commùnis, Linn. The classic Myrtle. Fig. 2427. A handsome evergreen shrub, 3–10 ft. or more (sometimes a small tree) high, both fls. and lvs. strongly scented: lvs. small in the variety usually cult., ovate or lanceolate, entire, smooth and shining, acute, coriaceous: peduncles solitary, 1-fld., length of lvs. or shorter, bearing 2 linear bractlets below the white and reddish pretty fls.: berry blue-black. Azores to Beluchistan; well known in the Medit. region. G.C. III. 45:18.—Several varieties are cult., which differ chiefly in the shape and size of the lvs. and in stature; there is also a variegated form. Makes a good hedge in S. Fla. Ever-blooming in S. Calif. It blooms in 2–3 years from cuttings in England. Following are some of the important named forms: Var. **melanocárpa**, DC. Fr. black. Var. **leucocárpa**, DC. Fr. white. Var. **latifòlia**, Hort. Lvs. very broad. G.W. 6, p. 595. Var. **microphýlla**, Hort. Lvs. small, dark green, linear-lanceolate and long-pointed. Var. **mucronàta**, Linn. Lvs. linear-lanceolate, acuminate. Var. **lusitánica**, Linn. Lvs. lanceolate-ovate, acute. Var. **itálica**, Mill. Shoots or branches nearly or quite erect, the lvs. rather small, ovate-lanceolate, sharp-pointed. Var. **boètica**, Mill. Branches short, lvs. crowded and thickish rather large, broadly ovate-lanceolate. Var. **bélgica**, Mill. Lvs. broad-lanceolate, long-sharp-pointed. Var. **angustifòlia**, Hort. Lvs. medium size, lanceolate. Var. **romàna**, Mill. Lvs. broad-ovate, large, sharp-pointed, light green, often 3–4 at a node. Var. **tarentìna**, Mill. Shoots short, lvs. ranged in 4 rows, short, ovate, sharp-pointed. Of some of the above, there are forms with variegated and white-margined lvs. and double forms. The different manifestations of *Myrtus communis* appear not to have been given adequate trial. It is not unlikely that the summers are too hot for them even where the winters are not too frosty; but there must be localities where they can be grown and treatments under protection of buildings or walls that would cause them to thrive. In ancient times, wreaths of myrtle were worn by magistrates and by victors. The plant yields perfumery, and the green and dried frs. are sometimes used as condiments. The wood is very hard and of interesting texture and grain.

Arayán, HBK. Lvs. 1–2 in. long, ovate-oblong, acute, membranaceous, reticulate, glabrous and shining: pedicels axillary, solitary, 1-fld., 2-bracted; fls. size of *M. communis;* calyx 5-parted: fr. globose, red, 2-celled and 2-seeded. Peru.—Listed in S. Calif.

Úgni, Molina (*Eugènia Úgni*, Hook. & Arn. *Úgni Molìnæ*, Turcz.). Ugni or Chilean Guava. As usually seen under cult., a shrub 4 ft. high, but in its native habitat it is said to become a tree 100 ft. high: pedicels 1-fld.: berry purple, glossy, edible, with a pleasant odor and taste. Chile; hardy in S. Calif. B.M. 4626. R.H. 1879, p. 409.—Wood very hard and heavy, much used in Chile for press-screws, and select implements.

M. Lùma=Eugenia apiculata, p. 1163.—*M. macrophýlla*, Spreng.=Eugenia malaccensis, p. 1163.—*M. tomentòsa*, Soland.=Rhodomyrtus tomentosa.

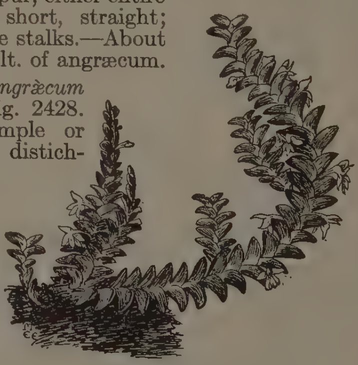
J. Burtt Davy. L. H. B.†

MYSTACÍDIUM (Greek, on account of bearded appendages of the column). *Orchidàceæ.* In habit resembling Angræcum. Sepals and petals similar, lip immovably attached to base of column, furnished with a long thin basal spur, either entire or 3-lobed; column short, straight; pollina upon 2 separate stalks.—About 20 species, in Afr. Cult. of angræcum.

dístichum, Pfitz. (*Angræcum dístichum*, Lindl.). Fig. 2428. Sts. 3–6 in. long, simple or branched: lvs. fleshy, distichous, grooved above, laterally compressed: fls. axillary, small, white. Sierra Leone. B. M. 4145. B. R. 1781.

M. gracíllimum, Rolfe. Scapes very slender; fls. white; spur long and very slender. Uganda.

George V. Nash.



2428. Mystacidium distichum. (×⅓)

N

NAEGÈLIA (Karl von Naegeli, once professor of botany at Munich). *Gesneriàceæ.* Trop. American herbs allied to Achimenes, but the fls. arranged alternately in a leafless terminal panicle (in Achimenes the fls. are axillary). In cult., the plants are oftener called gesnerias than naegelias, but they are distinguished from that genus in usually having an annular or ring-like disk at the base of the corolla, rather than a deeply lobed disk. Tubers usually none, the plant rhizomatous or repent: st. nearly simple: lvs. opposite, soft, long-petioled, usually cordate: fls. showy, mostly red, sometimes yellowish white or suffused, alternate in a terminal cluster with very small bracts at base of pedicels; corolla declined or hanging, oblique and usually more or less spotted in throat, much exceeding calyx.—Species about a half-dozen, Mex. and Cent. Amer. Naegelias hybridize with other gesnerias. One hybrid race is known as Naegelio-Achimenes and another (F.S. 10: 987, 988) as Mandirola. Because of the panicled fls., naegelias are very ornamental plants. They are warm-house subjects, prop. by stolons or offsets.

Because of conflict with another genus of the same name, Kuntze proposes the name Smithiantha for this genus; but the way seems to be clear for the use of the well-established Naegelia. See *Smithiantha.*

In general, the cultural methods given under Achimenes (Volume I, page 206) suit naegelias well (compare also Gloxinia). The roots should be stored in the pots in which they have been grown. It is a poor plan to keep any bulbs or tubers of the Gesneriaceæ in dry sand in a dry storeroom. After being well ripened, naegelia roots should be kept in the greenhouse under the benches. Keep them out of the drip, but water them occasionally. (T. D. Hatfield.)

A. *Fls. nearly scarlet, or brick-red, marked with white.*

cinnabarìna, Lind. (*Gesnèria cinnabarìna,* Lind. *Smithiántha cinnabarìna,* Kuntze). Fine winter-blooming plant, 1½–2 ft. tall, soft-hairy: lvs. round-ovate and cordate, crenate-dentate, thickish, green, with red or purplish hairs: fls. about 1½ in. long, hanging on the ends of spreading pedicels, gibbous-tubular to the very base, the calyx-lobes acute and spreading, the short corolla-lobes unequal and obtuse, the fl. cinnabar-red or nearly scarlet on the upper side, but paler and spotted on the under side. Mex. B.M. 5036. Lowe, 33. H.F. II. 5:4 (var. *rosea*).

AA. *Fls. orange-scarlet or scarlet, marked with yellow.*

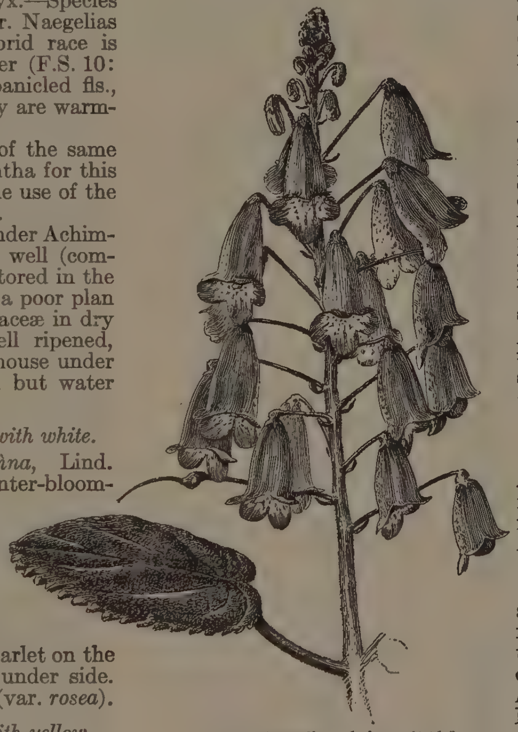
zebrìna, Regel (*Gesnèria zebrìna,* Paxt. *Smithiántha zebrìna,* Kuntze). Fig. 2429. Much like the above, but brighter colored, red-dotted below and yellow within and on the under side: calyx-lobes short and appressed; corolla contracted toward the base, whereas they are gibbous or swollen to the very base in *N. cinnabarina.* Brazil. B.M. 3940. B.R. 28:16. P.M. 8:271.—A fine plant, of which there are several forms. The commonest species. Names belonging here are *Gesneria regalis* and *G. splendens.*

achimenoìdes, Bart. (*Smithiántha achimenoìdes,* Fritsch). Hybrid of *N. zebrina* and Achimenes or Gloxinia (said to be with *A. glabrata;* see *Gloxinia,* Vol. III, p. 1350): fls. very large (often 2 in. long), yellowish rose on the outside, yellow and rose-spotted on the inside, the segms. clear rose.

AAA. *Fls. white, cream-color or rose.*

multiflòra, Hook. (*N. amábilis,* Decne. *Smithiántha amábilis,* Kuntze. *Gesnèria amábilis,* Hort.). Fls. white or cream-color, numerous, hanging, the tube curved and not much swollen, the obtuse lobes subequal: plant bearing long, glandular hairs in addition to the velvety covering: otherwise much like *N. zebrina.* Mex. B.M. 5083. F.S. 12:1192 (as *Achimenes* [*Naegelia*] *amabilis*). G.C. III. 22:413. Gn. W. 23:335. G. 22:631.—The tenable name of this species is sometimes held to be Decaisne's *N. amabilis,* which goes back to 1857, but *Gloxinia multiflora,* Mart. & Gal., dates from 1842.

hyacínthina, Carr. Of horticultural origin, probably a hybrid: fls. white or rose, in a very compact pyramidal panicle. R.H. 1877, p. 29.



2429. Naegelia zebrina. (×½)

N. fúlgida, Ort. Fls. vermilion: lvs. large, oval, deeply toothed. Mex.—*N. Geroltiàna,* Regel (Smithiantha Geroltiana, Kuntze). Continuous-flowering plant, allied to N. zebrina. Mex. F.S. 2:97.—*N. sceptre corail,* Carr. Fls. many in an open panicle, cinnabar-red, yellow-spotted inside. R.H. 1869, p. 154 and col. pl. For pictures of varieties and hybrids, see F. S. 16:1671-1672; 10:987-988.

L. H. B.

NAEGÈLIO-ACHÍMENES is a former trade name mentioned under *Naegelia.*

NÀMA (Greek, a *stream* or *spring,* referring to habitat of the first-described species). *Hydrophyllàceæ.* Low herbs or subshrubs, little known in planting. Annual and perennial, sometimes spiny: lvs. mostly alternate, entire, dentate or crenulate: fls. blue or white, solitary or in various clusters; corolla campanulate or nearly salverform to funnel-shaped or somewhat rotate, 5-lobed; stamens 5, inserted in base of corolla-tube, the filaments usually dilated or appendaged at base; styles 2, with small capitate stigmas: fr. a membranaceous ovoid or subglobose dehiscent caps.—Species 36, as defined by Brand in Das Pflanzenreich, hft. 59 (IV. 251:1913), mostly in W. N. Amer. and Mex., but also in W. Indies, S. Amer., and 1 in Hawaii. One species is offered as a garden plant in Calif.

Párryi, Gray (*Eriodíctyon Párryi,* Greene). Shrubby perennial, 3–6 ft., stove, the st. over ½in. diam.: lvs. many, dark green, linear or linear-lanceolate, dentate or undulate, villous, sessile: fls. violet-blue in small lateral clusters that are aggregated into a long terminal spike or narrow thyrse; sepals oblong-lanceolate; corolla tubular-funnelform, about ½in. long. Calif. May–July. L. H. B.

NAMES AND NOMENCLATURE. Every plant that is known and recorded must have a name or appellation; the system or scheme of naming is known as nomenclature (pronounced nò-menclature).

It is now the universal custom with botanists to name a plant with two words,—one designating the genus or group into which it falls, and the other distinguishing the particular plant from all other plants in the group. The genus or group may be *Rubus*, the raspberries, blackberries and dewberries; the particular species of Rubus may be *villosus;* and the complete name is therefore *Rubus villosus*. It will be seen, therefore, that this two-word or binomial appellation both classifies and names the plant. When other species of Rubus are discovered, they receive special, or specific, names in the genus, as *R. frondosus*, *R. allegheniensis*, *R. Millspaughii*.

In scientific language, a plant may have only one name. Confusion would arise if it had two or more. But it sometimes happens that two or more persons give a name to the same species (either because unaware of an earlier name or because the authors regarded a given form of the plant as a distinct species or as separate enough to receive another name), and to distinguish one name from another the author's name goes with the plant-name that he makes. So it comes that "*Rubus villosus*, Ait.", means that the name *Rubus villosus* was made by Aiton. Botanists know when and what Aiton wrote: therefore they can trace the name and description to its source. "*Rubus villosus*, Gray," may be a very different plant; but only the oldest name, if it is the proper or accepted genus, may stand, and all other names become synonyms or duplicates. It happens that the *Rubus villosus*, Gray, is not a species so named by Gray in ignorance of Aiton's name, but a misapplication of Aiton's *R. villosus* to another species than that which Aiton had in hand, as will be understood from the narrative below.

2430. Some of the cases in which is kept the priceless herbarium of Linnæus.

It would seem to the layman to be the simplest matter to make the name *Rubus villosus*—*villosus* is only a Latin word signifying "hairy;"—but, in fact, it is a serious undertaking. It is always considered the mark of a good botanist that he make new names with the greatest caution. In the first place, it is allowable to make a name only when the plant is nameless. When the botanist finds a plant that he suspects to be new, he must exercise all reasonable caution to determine whether anyone in all the world has named it. He must determine its genus, and be able to write a sufficient description of it. He must give it a name that has not been used before in that genus: if any plant has been named *Rubus villosus*, he cannot give another rubus that name. Then he must publish the name and description in some publication of recognized standing; and once published, it is established in botanical literature and neither he nor anyone else can ever modify it. Always is his own name associated with the name of the plant; and if the name is an error or the description inaccurate, he must take the responsibility so long as botanical literature shall last.

The description is made for the purpose of enabling anyone to identify the plant. Amongst the hosts of plants, however, the confusion may be so great that even the best description will not positively identify the plant. A picture will help, and illustrations are often published when the plant is first described. But a poor picture may be misleading and thereby be worse than none. Every botanist, therefore, preserves a specimen or specimens as a type of his new species. This specimen is dried, "mounted" or stuck on a sheet of stiff white paper, and laid away in the herbarium. Custom dictates that this sheet of paper shall be about 11½ inches wide and 16⅜ inches long; and only one species is glued on a sheet (see *Herbarium*, Volume III). In case of dispute, this type specimen is consulted, and it takes precedence over descriptions and pictures. It alone is final, as determining what plant the author meant to designate by the name. Even the author himself cannot ignore or replace the original "type specimen;" it is part of the ethics of the profession that this specimen shall not be destroyed or modified. So it happens that type specimens become increasingly valuable as time goes on.

The larger part of the new species are "made" or described at the great centers of botanical study, and the specimens are preserved in these public or semi-public collections; but any botanist anywhere may describe a new species, in which case he may send his type specimen or an authentic duplicate of it to one of the great herbaria, where it may be consulted by other students; and at his death his collections are likely to find their way to one of the botanical centers.

In all the great collections, quantities of unnamed or undetermined specimens may accumulate, particularly from travelers in little-frequented regions. In time, some student of the flora of the region may study these specimens, perhaps finding undescribed species among them; or a student of one special group may go over them to find the plants that fall within the range of his studies; or if the given accumulation is interesting and valuable in itself, some student may study it as a collection and publish on it, describing new species, adding to the descriptions of recognized species, and correcting ranges and habitats. Specimens and even whole collections are sometimes loaned to reputable students of special groups. These specimens are always to be returned without subtraction, injury or modification. Very often the student, in returning the specimens, adds material of his own to enrich the collection. It will be seen, therefore, that the herbarium becomes more precious year after year as successive students contribute their interpretations to it.

While the above outline may seem to make the naming of plants a relatively simple and direct process, nevertheless many complications and confusions may arise. First of these difficulties are the varying interpretations placed on the specimens by the different students, some of them regarding differences as having specific value (wide enough to justify the separation of the material into two or more species) whereas others may consider them to be only variations within the species. The process of combining, separating and recombining introduces many names of different relative values, all of which must be considered and accounted for by subsequent students or authors. Again, older authors may be found, in books or publications overlooked, who have made names and descriptions. Or the rules of nomenclature accepted by different botanists may not be harmonious, and the differences must be adjusted as completely as possible. There may be different standards or conceptions of genera between different authors, resulting in shift and re-shift from genus to genus. These and other situations make the subject of botanical nomenclature very complicated.

Some of the inharmonies in nomenclature have been resolved by the action of botanical congresses, but there is yet wide divergence in practice and it is difficult to foresee any close agreement even in the formal rules and precepts, while it is scarcely to be expected that concurrence can be attained in the underlying concepts as to what are species and what are not, although it ought not to be impossible to reach something like a uniformity on genera.

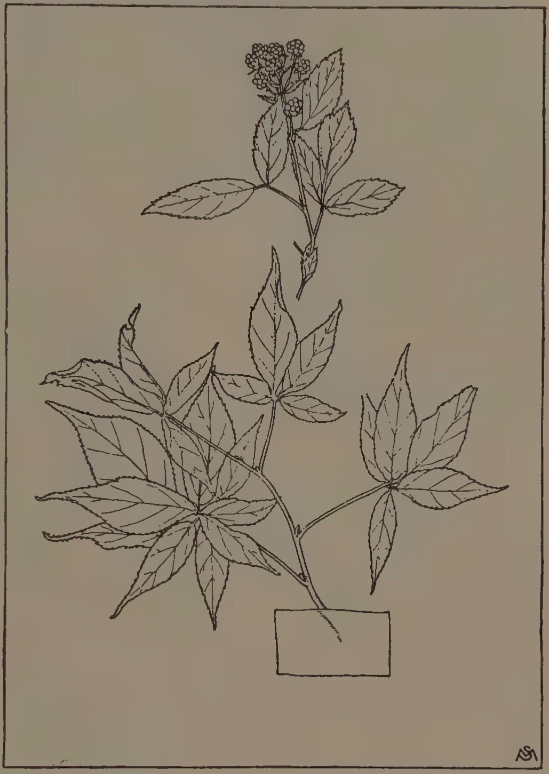
The situation of this Cyclopedia.

A cyclopedia of horticulture includes species from around the world, deriving its names and descriptions from the publications of many countries; its nomenclatorial method should be international so far as such a method exists. Therefore, this Cyclopedia follows, as a policy, the regulations of the International Botanical Congress held in Vienna in 1905 (see page xi, Volume I). It would not be desirable, as it would also not be practically possible, to endeavor in a compilation of this kind, and for popular use, to recombine the names of plants from all over the world to conform to any special or regional school of nomenclature.

The Cyclopedia is not primarily a botanical treatise. Its first obligation is to the horticultural fraternity, to those who apply and use the results of botanical study. It must regard the value of names that are long established in commerce and in literature. Binomial names do not belong exclusively to botanists. There is merit in usage and in the end it controls. Whenever all botanists of authority agree upon a set of changes, the horticulturists should of course adopt them; but a cyclopedia of this kind is not under obligation to be "up to date" in respect to recent changes that may represent only individual opinion or which are likely to be overturned or at least not adopted by other botanists of standing. So far as possible, a cyclopedia of horticulture should represent settled practices. This work, therefore, adopts a conservative attitude in nomenclature.

The International or so-called Vienna rules contain regulations or "articles," and recommendations. The articles deal with the principles, and the recommendations with cases and practices. The articles are broadly stated and often allow of considerable latitude of application; and the recommendations are left to the option of the author. Therefore, the application of the Vienna Rules is not invariable.

But other and somewhat opposite considerations weigh in the compilation of the Cyclopedia, seeing that many authors contribute. While it is desired that all these authors conform as nearly as practicable to one system, nevertheless the author himself, when he is a special and authoritative student of the group, must be allowed to use his preferred method even though the combined result as between the different articles should prove to be somewhat inharmonious. A distinction is clearly to be made between work that is compilatory and editorial, and that which is the result of original studies with the material; the former may follow the accepted method of the Cyclopedia, but the latter may follow the method of the particular author's monographic work. Thus it is, for example, that the citrous tribes, the cacti, and some of the groups of trees and shrubs, present such wide departures.

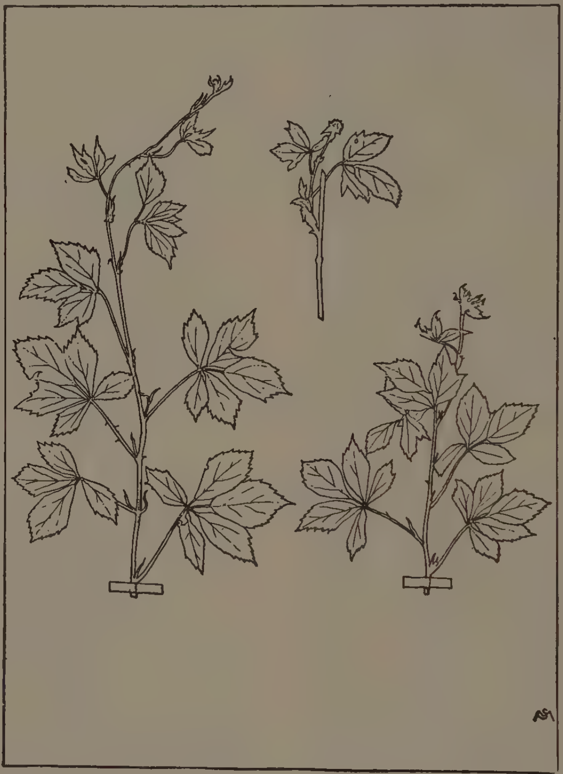


2431. Linnæus' sheet of Rubus canadensis.

It has been the desire, however, to avoid the making of new binomials or combinations, for the cyclopedia is not intended as a "place of publication" of botanical names. In the course of the work, however, it has been impossible to avoid re-combinations in some cases and yet present the subjects acceptably.

Double citation of authorities for botanical names has been avoided. This is in the interest of simplicity and convenience. The double citation is for the use of botanists to aid them in tracing the history of the name. The identification of a name by citing the author of it, is one thing; the record of the history of a name in the double citation is quite another thing. But whatever the justification in technical botanical work, the gardener and the horticulturist in general should not be burdened with these details, particularly when they are cumbersome and awkward in themselves. Thus, *Lippia nodiflora*, Michx., is sufficient for our purpose, showing that Michaux first used this combination; the double citation is *L. nodiflora*, (Linn.) Michx., showing that the use of *nodiflora* as a name for this plant began with Linnæus under another genus, although the double citation does not indicate the number of transfers from genus to genus that may have been made in the meantime.

In the prefatory pages to Volume I, the method of nomenclature employed in this Cyclopedia is briefly stated; but it may be well to make an explanation of the use of capital letters in specific names. It is the rule in English that proper adjectives are capitalized, as American, African, Canadian. This is not the practice in all other languages, however. For the sake of uniformity, it is now the practice with many authors to decapitalize all specific names. The specific name should agree with its genus in gender; but some of the old substantive or generic names are used as specific names in defiance of gender terminations, and the use of the capital letter explains the exception. Thus *Dracocephalum Moldavica* indicates that Moldavica is an old substantive (used once as a genus) and is used in apposition and not as an adjective; otherwise it would be *D. moldavicum*, meaning the moldavian dracocephalum. Other substantives are not Latin and cannot be Latinized, as *Dolichos Lablab;* the word Lablab is not an adjective qualifying Dolichos. Bearing these distinctions in mind, such names as *Campanula Medium, Dioscorea Batatas, Cornus Amomum, Schinus Molle, Mapania Pandanophyllum* are understood. The Vienna Code makes a recommendation on the use of capitals: "Specific names begin with a small letter except those which are taken from names of persons (substantives or adjectives) or those which are taken from generic names (substantives or adjectives)." Under this recommendation, descriptive names are not capitalized. A special category are the geographical names, but they may be fairly regarded as descriptive and be used with small letters; this is the practice in this Cyclopedia, for the purpose of conforming to the recommendation. A few confusions arise in decapitalizing geographical names. For example, *Syringa persica*, one of the lilacs, takes the small p because the name means Persian; whereas *Prunus Persica*, the peach, takes the large P because the word was once used for a genus (*Persica vulgaris*, the peach), although that generic word was derived from the country Persia whence the peach was supposed, at that time, to have come. In some cases, the same or similar specific names may be personal or geographical, and many geographical names are derived directly from persons, as Bolivia, Rhodesia, Colombia, America; but in practice little or no confusion arises. The practice in this Cyclopedia, then, is to capitalize specific names derived from persons (either in the genitive as *Hookeri*, or in adjective as *Hookeriana*), and all substantives used in apposition, as *Pyrus Malus, Alpinia Allughas, Vaccinium Vitis-Idæa, Phlox Stellaria, Ipomœa Nil, Polygonum Posumbu.*



2432. Aiton's sheet of Rubus villosus, preserved in London.

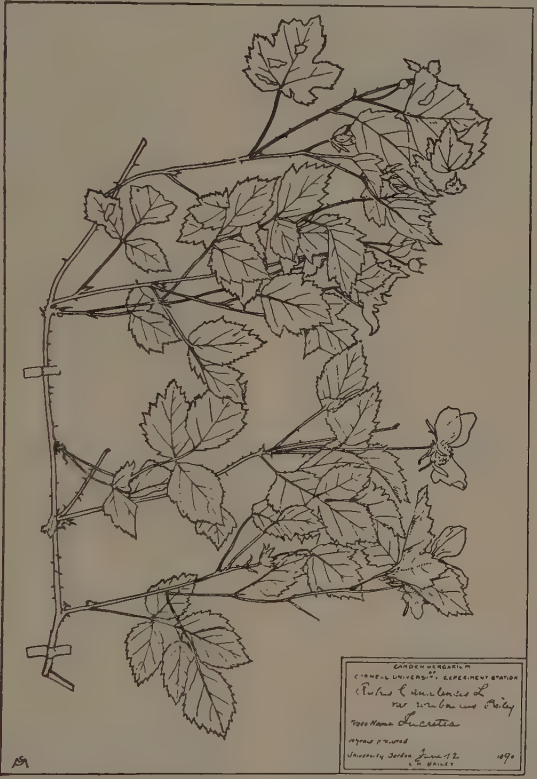
How a plant is named.

A personal narrative may illustrate some of the complexities in nomenclature. The case that is here chosen for elucidation is not more interesting or important than scores of others that might be taken from the experiences of botanists, but it will afford an example.

Blackberries and dewberries (which are of the genus Rubus) are variable. This is the botanist's way of saying that there are many intermediate forms and that it is difficult to distinguish one kind from another. On different soils and in different places, the plants look different. They may intergrade. With them, evolution has probably not yet proceeded far enough to obliterate the intermediates, and the "missing links" may not have disappeared. The species are not "well marked." Therefore it is not strange that botanists disagree as to what are species and what are varieties of species. What one botanist calls a species of Rubus, another prefers to call a variety, or a mere "form" perhaps due to influence of soil, elevation or exposure. The general tendency is to make more species in all genera than did the old botanists, because we know the plants more intimately and recognize differences that were not seen or understood one hundred years and more ago. What Linnæus thought was one species we may now think is several; and if we break up his one species into several, we must know which one of these forms he had, in order that we may retain his name for it;—and we determine this fact by consulting his herbarium (if a specimen is preserved) which is now in London.

Or, again, we may misunderstand what Linnæus meant to designate by a given name, and may use his name for a different plant from that which he had in mind. Even if we see his specimen, we may make an error in identifying it,—for it is not always an easy matter positively to identify and classify a dried specimen, particularly if the specimen was fragmentary or poor in the beginning or has become broken or insect-eaten. It sometimes happens, therefore, that when two men examine the type specimen of a "critical" species, they arrive at different conclusions as to what that species is. Each may publish his views, applying the name as seems right to him, and botanists choose the one determination or the other according as they accept one man or the other. The naming of plants, therefore, is not an exact procedure.

The name "*Rubus villosus*" is one that Aiton gave in 1789 to a plant that grew in the gardens at Kew, near London. The plant, he said, came from America. It was described in brief Latin phrase, with little indication as to its habit of growth. Before this time, even as early as 1753, Linnæus, the great Swede, had described a blackberry, which the traveler Kalm had discovered in Canada, as *Rubus canadensis*, the "Canadian rubus." In 1809, Willdenow, a Prussian systematist, described *Rubus inermis*, from specimens growing in the Botanic Garden at Berlin, said to have come from America; and in 1822, Link, also of Berlin, described, under similar circumstances, a plant that he called *Rubus argutus*. When American botanists began to write books, in the early part of the nineteenth century, two well-marked species of blackberries were made out,—one a trailing plant or dewberry, and the other an upright plant or high-bush blackberry. The descriptions given by Linnæus and Aiton were looked up and compared: the *Rubus canadensis* of Linnæus was thought to designate the dewberry, and the *Rubus villosus* of Aiton the high-bush blackberry. Since there were only two wild blackberries, the names made by Willdenow and Link must be mere duplicates; and they were regarded as synonyms of *Rubus villosus*, having no standing in the manuals.



GARDEN HERBARIUM OF CORNELL UNIVERSITY EXPERIMENT STATION
Rubus Canadensis L
var roribaccus Bailey
Trade Name Lucretia
University Garden June 12 1890
L H BAILEY

2433. An herbarium sheet of a form (var. roribaccus) of Rubus villosus.

Years passed. Botanists found that the rubuses did not match the descriptions in the books and they seemed to "run into each other," so that they could not be clearly separated or told apart. Therefore they were not carefully studied, for it has been the history of botany that the "best defined" species have usually been collected most freely, so completely have we been dominated by the old idea of the original entity of species. But gradually the dried specimens accumulated in the herbaria. One by one the puzzling genera were taken up for study. Finally Rubus had its turn.

It was found that there are several species of blackberry-like plants growing wild in the eastern states, rather than two. Amongst the rest was found a thornless blackberry in the mountains of West Virginia, and in 1891 it was named *Rubus Millspaughii*, in honor of C. F. Millspaugh, its discoverer. Thereupon botanists searched their herbaria, and sprigs of the plant were found, under various names, representing collections from Canada to Carolina. But there were still other species than this, and it began to be seen that the botany of American rubi is complex. This fact should have been no surprise, for the European species of rubi have long been known to be amongst the most puzzling of plants. What should be the names of these newly understood species? Linnæus and Aiton were consulted, but their descriptions did not distinguish. The type specimens must be seen.

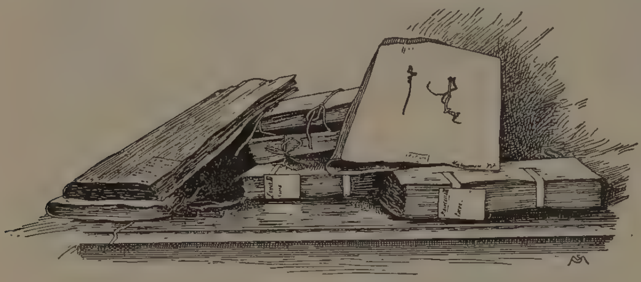
It seemed to fall to the writer to undertake the inquiry. To see the two dried plants of Linnæus and Aiton did not seem worth a trip to Europe. Therefore an artist near London was engaged to make a drawing of Linnæus' specimen in the rooms of the Linnæan Society, in Picadilly, and of Aiton's in the Natural History Museum at South Kensington, London. These pictures gave such unmistakable evidence that we had misunderstood these old botanists, that it seemed desirable not to publish the results until the specimens had been examined. The picture of Linnæus' plant left little doubt as to the identity of the species that he had, but that of Aiton's was a puzzle, for it seemed to represent clearly no American blackberry.

In the Linnæan herbarium is the sheet of *Rubus canadensis* (Fig. 2431), supposed for nearly a century and a half to represent the common running dewberries of the fields, but which was identified to be in reality the *Rubus Millspaughii* of recent years. From the time that Peter Kalm collected the plant in Canada before the middle of the eighteenth century until 1891, this plant had been overlooked. Now, therefore, this thornless blackberry must be known as *Rubus canadensis*, and the name *Rubus Millspaughii* becomes a duplicate or synonym having historic and literary value, but no longer to be used, if the determination is correct, as the name of the plant. In the meantime, the common dewberry, erroneously known as *Rubus canadensis*, is left without a name.

In the collections of Aiton is his specimen of *Rubus villosus* (Fig. 2432). It is difficult to determine just what this plant is, because the specimen was taken from the tip of a strong verdurous shoot, and therefore does not represent the usual form of any blackberry as seen in herbaria. It is, in fact, the tip of a prostrate shoot of the common dewberry, the very plant to which we had supposed Linnæus gave the name *Rubus canadensis*. The dewberry (Fig. 2433), therefore, must be called *Rubus villosus*, notwithstanding the fact that the name itself is not specially appropriate; but the tips of strong shoots—rarely mentioned in descriptions—are somewhat hairy. But a name is a name, not a description; and even though it is inappropriate as to the attribute it seems to ascribe to a plant, it still serves all the purposes of a designation. This unrepresentative specimen proved to be very puzzling; and a year later it was re-examined; and in the collection at South Kensington specimens were deposited of the tip growths of the dewberry which are good counterparts of Aiton's old type.

The thornless blackberry and the dewberry were now provided with names; but the common high-bush blackberry of east-American fields, which we had been accustomed to call *Rubus villosus*, was left nameless.

In the effort to find a name for the high-bush blackberry, the Rubus names given by Willdenow and Link must be accounted for. The descriptions made by these authors are not sufficient positively to determine the plants. The dried specimens themselves must be seen in Berlin. Willdenow's name, *Rubus inermis*, suggests that it may have been applied to the thornless blackberry, for *inermis* means "without thorns." In the great herbarium at the Botanical Garden, Willdenow's plants are preserved in stout blue paper wrappers (Fig. 2434). His *Rubus inermis* is amongst them (Fig. 2435), but it turns out to be a blackberry of Greece. In the old garden at Berlin, early in the century, American and European plants were growing, each species occupying a little space of earth and marked by a stake label. In time, one of the American plants probably had perished and a Grecian plant occupied its place, growing behind an American stake. Specimens of the plant were taken for the herbarium, and not recognizing it as an American plant, Willdenow described it as a new species; but before his time this Grecian plant had been described as *Rubus ulmifolius*—the "elm-leaved rubus"—and Willdenow's name, supposedly applied to an American plant, now becomes a synonym of a European species.



2434. Bundles from the herbarium of Willdenow.

Willdenow's name having failed us, we next take up Link's *Rubus argutus* (Fig. 2436), and here is still another difficulty; it is an American plant, but of a distinct species from the high-bush blackberry. Other names, not mentioned in this account, must be considered,—Trattinnick's, with specimens in Vienna, Michaux's in Paris, Bigelow's of Boston, and others. All were looked up, and none of them could be applied to the common blackberry, and the plant was given a new name, *Rubus nigrobaccus.*

It must not be supposed, however, that the case was now disposed of and settled. Every subsequent student has the liberty of his own interpretation. Some botanists consider the common *Rubus nigrobaccus* to be but a form of *R. allegheniensis* of Porter, a name which dates from 1896 whereas *R. nigrobaccus* dates from 1898; in this case, *R. allegheniensis* holds and *R. nigrobaccus* becomes a synonym. So all the other forms may be separately judged, and every author has the right to his own judgment and to the use of the name that goes with it. Other interpretations have been made more recently as to the species-lines in Rubus. In a group so difficult and variable as Rubus, the judgments naturally will be diverse and agreement is not to be expected, perhaps not even to be desired.

(See name lists, end Vol. VI.) L. H. B.

Historical development of botanical nomenclature.

The present universally accepted binomial nomenclature started in 1753 with the publication of Linnæus' "Species Plantarum," when for the first time all known plants were named according to a uniform system based on the principle that for the designation of a plant two names, a generic and a specific, each consisting of one word only, should be sufficient.

Before that time there was no uniformity in naming plants; most of them were designated by longer or shorter descriptive phrases, as *Aralia caule aculeato, Narcissus niveus odoratus circulo rubello, Mespilus apiifolio virginiana spinis horrida fructu amplo coccineo, Acer foliis palmato-angulatis floribus subapetalis sessilibus fructu pedunculato corymboso;* others by a single Latin or vernacular name, some by common nouns like *Centrum galli, Corona imperialis, Capillus Veneris;* not unfrequently the descriptive phrase was reduced to one word, as in *Iris germanica, Nymphæa lutea, Berberis vulgaris,* combinations which were already in use in the sixteenth century. This more or less lawless naming is usually referred to as pre-Linnæan nomenclature. Its beginnings may be traced back more than 2,000 years to the writings of Theophrastus (371–286 B. C.), a disciple of Aristotle, to the works of Pliny (33–79 A. D.), and of Dioscorides, who lived at nearly the same time, and to other ancient writers. Later writers on natural history and medicine up to the fifteenth century added little to the knowledge of the plant world; their writings consisted chiefly of commentaries to the classical works and of scholastic discussions on the meaning and application of the names used by the ancient writers and on the medical virtues of the plants as set forth by them. A new era started in the beginning of the sixteenth century when men like Brunfels, whose "Herbarum Vivæ Eicones" appeared in 1530, Bock, Fuchs and Cordus, began to study the native plants and found that many of them were unknown to the old writers; they published figures drawn from nature and descriptions of these new plants and gave new names to them. The coining of botanical names derived from personal names was inaugurated at that time, and Conrad Gesner (1516–1563) was probably the first one to name plants in compliment to his friends, e. g., Cortusa, Aretia, Vollata and others. A fairly complete enumeration of the plant names with their synonyms known up to 1623 was published in that year by Caspar Bauhin in his "Pinax Theatri Botanici;" this work shows the extent of the botanical knowledge at that time and is valuable as a key to the nomenclature of the older writers.

Progress in nomenclature is hardly possible without classification. In the earlier works the plants were either enumerated alphabetically or roughly divided into trees, shrubs and herbs or arranged according to their uses. One of the first attempts toward classification was made by Cesalpini in his "De Plantis Libri XVI" (1583), who arranged the plants roughly according to their fruits. Other more natural systems and at the same time a clearer conception of genera and species were introduced by Jung, Morison, Ray and Rivinus.

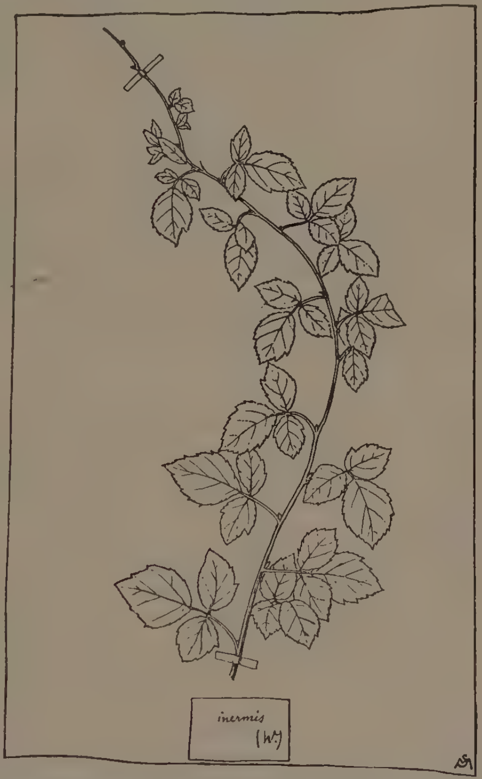
Morison was the first botanist to publish a monographic treatment of a natural group in his "Plantarum Umbelliferarum Distributio Nova" (1672). Ray in his "Methodus Plantarum Nova" (1682) distinguished families like Labiatæ, Papilionaceæ, Siliquosæ (Cruciferæ), Grasses, Monopetalæ, while Rivinus based his classification chiefly on the corolla and distinguished Monopetalæ with regular and with irregular flowers and Pentapetalæ and Tetrapetalæ with the same subdivisions. The older writers had often united under one generic name very different plants: e. g., *Clematis sylvatica latifolia* (=*Clematis Vitalba*), *C. daphnoides* (=*Vinca minor*), *Clematis tetraphylla* (=*Bignonia capreolata*), *C. indica* (=*Passiflora*); and as another example, *Viola Martia purpurea* (=*V. odorata*), *V. matronalis* (=*Hesperis matronalis*), *V. lunaria* (=*Lunaria rediviva*). The botanists named above, in consequence of their better understanding of natural affinities, proved the unnatural character of such genera and divided them into different genera under distinct names.

In 1700, Tournefort published in his "Institutiones Rei Herbariæ" a complete enumeration of all the known genera with descriptions and illustrations; he is considered the founder of the modern conception of the genus and of its nomenclature, and therefore the year 1700 has been proposed by some botanists as the starting-point for generic nomenclature. Tournefort, however, still retained a few of the inconvenient generic names which consisted of two words, as *Corona imperalis*, *Centaurium minus* and *Centaurium majus*, *Ferrum equinum*. These disappeared forever with the publication of Linnæus' "Genera Plantarum" in 1737, which contained, like Tournefort's work, a complete enumeration of the known genera, but much clearer and more concisely characterized and arranged according to the sexual system of which Linnæus had published an outline two years before. About the same time, in 1736 and 1737, Linnæus laid down his principles of botanical nomenclature in his "Fundamenta Botanica" and "Critica Botanica," but it was not until 1753 that he took the last step in his reform of botanical nomenclature and proposed for each known species a *nomen triviale*, that is a name which consisted of a single word and was intended to replace for general use and reference the cumbersome descriptive phrases previously used.

This simplified and convenient nomenclature found the speedy approval of nearly all botanists and was soon universally adopted. Very few botanical works of importance were published after that time which did not accept the binomial nomenclature; the most notable are perhaps Patrick Browne's "Civil and Natural History of Jamaica" (1756), and the sixth edition of Philip Miller's "Gardeners' Dictionary" (1759), but in the seventh edition (1768) Miller adopted the binomial nomenclature. Although little or no objection was raised against the nomenclatorial system itself, many attempts were made to change specific and also generic names for various reasons; for example, Salisbury in his "Prodromus Stirpium in Horto ad Chapel Allerton Vigentium" (1796) conceived the idea that all specific names ought to be descriptive adjectives and therefore changed names like *Lonicera Caprifolium* to *L. suavis*, *L. Periclymenum* to *L. odora*, *Rhamnus Frangula* to *R. nemoralis*, and others. Likewise many other botanists felt themselves at liberty to change names they did not like or did not consider quite correct, and the law of priority had little weight up to the first quarter of last century. The general tendency was then, and in fact has been for a much longer time, to give preference to names published in important and easily accessible works and to follow the lead of men considered to be great authorities. Fortunately, nearly all great systematic botanists, about the middle of last century, as the De Candolles, Endlicher, Martius, Hooker, Bentham, Asa Gray, Baillon, were more or less guided by the law of priority, but with the increasing botanical activity about that time the necessity was felt to have definite and uniform rules for the ever-increasing number of botanical workers. Therefore Alphonse De Candolle was charged to prepare for the International Botanical Congress at Paris in 1867 a code embodying the rules to be followed in botanical nomenclature. The code which was presented to the Congress and adopted contained as the fundamental principle the strict observation of the law of priority. It ruled that in transferring a species from one genus to another the oldest specific name had to be preserved; also that in changing a variety to a species or *vice versa* the oldest name must be retained. Although most continental botanists followed more or less this Paris Code, or as it is sometimes called Candollean Code, the British botanists under the leadership of Kew preferred the first combination under the correct genus, the so-called Kew rule. The Paris Code, however, even by its professed adherents, was hardly ever applied consistently in all its consequences. This was pointed out forcibly by Otto Kuntze in his "Revisio Generum," of which the first part appeared in 1891; in this work he essayed a rigid application of the Paris Code, resulting in thousands of new combinations under hundreds of unfamiliar generic names. This avalanche of new names raised a storm of protest in many quarters. For years Kuntze fought for the strict application of the Paris Code of which he proposed several amendments, and for the acknowledgement of his new names, but his uncompromising and unyielding attitude and the often intemperate language used against those in opposition made him many enemies, and he therefore did not accomplish so much as he might have effected, if he had tried more persuasive methods; but nevertheless he set the reform under way.

In 1892 the Botanical Club of the American Association for the Advancement of Science at the Rochester meeting drew up a short code of eight articles, somewhat amended at the Madison (Wisconsin) meeting the following year, which embodied about the same rules as were contained in the more amplified Philadelphia Code of 1905. In the following year, the International Botanical Congress at Genoa added a few but rather unimportant amendments to the Paris Code. In 1897, the botanists of the Berlin Botanical Museum agreed on a set of rules mainly for the guidance of the collaborators of Engler & Prantl's "Natürliche Pflanzenfamilien." The chief feature of these rules was a provision against replacing well-known generic names by old half-forgotten names which had failed to become established within fifty years after their publication, thereby allowing the principle of usage to predominate in certain cases over the principle of priority.

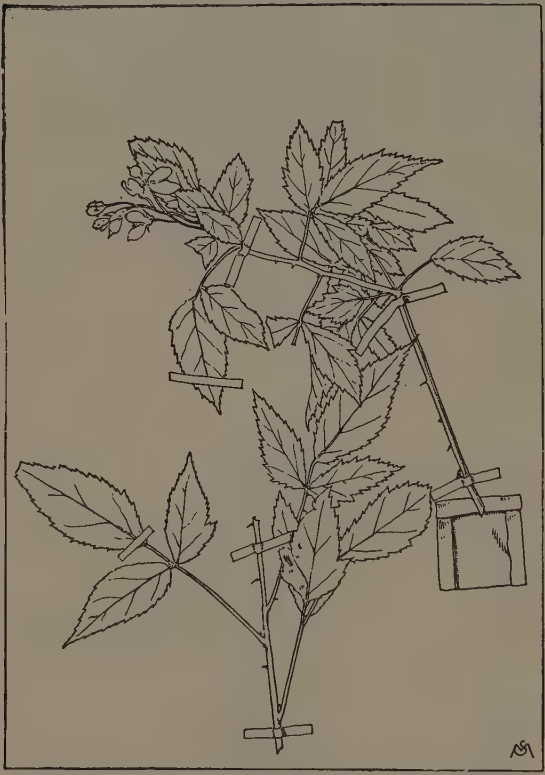
In 1900, at the International Botanical Congress at Paris, a commission was formed to make the necessary arrangements for a representative meeting of botanists at the time of the Congress at Vienna in 1905 to come to some agreement on the fundamental rules of nomenclature. Botanists of the whole world were invited to make propositions and amendments to the Paris Code, which had been decided upon as the base of the new code. Propositions were freely offered, and all were incorporated in a publication which was sent to lead-



2435. Willdenow's specimen of Rubus inermis, in Berlin.

ing botanical institutions and to those botanists who had offered propositions. During the Congress the different propositions were discussed and voted upon by a representative gathering of botanists of the whole world in special nomenclatorial sessions which extended through a whole week. The new code, which was the result of this Congress, is known as the International Rules, sometimes called Vienna Code.

The fundamental principle of this code is the acceptance of the law of priority with 1753 as the starting-point for the nomenclature of the vascular plants. However, to avoid disadvantageous changes in the names of well-known genera, a list of about 400 generic names, "nomina conservanda," was provided which must be retained in all cases. The oldest specific name, under whatever genus it had been published, is to be preserved in transferring a species from one genus into another except when the same combination already exists in the new genus, e. g., *Azalea pontica*, if transferred to Rhododendron cannot become *R. ponticum*, as this combination already exists for another species in the genus. Also a specific name must be changed if it repeats simply the generic name in the new genus, e. g., the specific name of *Bignonia Catalpa* when transferred to Catalpa must be changed, as *Catalpa Catalpa* is not admissible. Varietal and specific names cannot compete with each other; that is, for a variety the oldest varietal name given under any other species or genus holds, even if there should be an older specific name for the same plant, and *vice versa.* Under the Paris Code, however, the oldest name must be retained in any case whether published as a specific or as a varietal name. When two or more groups with names of the same date are united, the author chooses. A name or combination of names which is universally regarded as a synonym may be used again for another plant, although it ought to be avoided. The whole code contains fifty-eight articles and thirty-seven recommendations. It gives detailed rules for the formation of names, citation of authors, validity of genera, species and varieties, transfer of species and varieties, changes of names, rejection of names, and other practices. A conveniently accessible reprint of the English version of the code will be found in Rhodora 9:33–55 (1907). There are also German, French and English versions in "Verhandlungen des Internationalen Botanischen Kongresses in Wien 1905," published in 1906 by Gustav Fischer in Jena.



2436. The sheet of Link's Rubus argutus in the herbarium at Berlin.

A number of American botanists had submitted to the Congress an entirely new code and proposed that it should be accepted instead of amending the Paris Code. This, however, could not be done, as it was understood from the beginning that the new code should be based on the Paris Code. After the Congress, the authors and supporters of this new code came together and voted not to accept the decision of the International Congress, but to retain their code, which is known as the Philadelphia Code or American Code. Only in one point was a change introduced and the decision of the Vienna Congress followed, namely, that specific and varietal names cannot compete with each other. In the Philadelphia Code, much stress is laid on the method of types. to which little attention is paid in the International Rules. Besides this the following points are the most important in which the two codes differ. The Philadelphia Code recognizes no exceptions in the priority of generic names; it has no list of "nomina conservanda." In the case of union of group-names published at the same time in the same book, those having precedence of position in the publication or on the page are regarded as having priority. A name or combination of names can never be used a second time for a different group, while according to the International Rules it can be used again if the older is not valid. In transferring a specific name to another genus, repetition is allowed, which makes names like *Glaucium Glaucium* and *Symphoricarpos Symphoricarpos* admissible. The use of the genitive and the adjective form of the same personal name for different species in the same genus is not admissible, while according to the International Rules they cannot be rejected, e. g., *Lysimachia Hemsleyi* and *L. Hemsleyana* are admissible according to the International Rules, but not according to the Philadelphia Code. The whole Philadelphia Code contains nineteen canons, besides rules on orthography, citation, and other matters. It is published in the Bull. Torr. Bot. Club. 34:167–178 (1907).

In 1910, the International Botanical Congress held at Brussels added several amendments to the International Rules and fixed the starting points for the nomenclature of the lower cryptogamous plants. In conjunction with this congress, an International Horticultural Congress was held, of which a subsection on nomenclature was charged to consider nomenclatorial questions in regard to horticulture. It was resolved that the International Rules should be accepted with a few exceptions and modifications concerning the nomenclature of horticultural varieties and hybrids. The employment of Latin names for horticultural forms is restricted to descriptive terms like *compactus, nanus, fastigiatus;* other names ought to be given in a vulgar tongue and must not be translated when transferred to other languages; the names should be expressed so far as possible in one word, the employment of three words to be the maximum. Bigeneric hybrids ought to receive a generic name formed by the combination of the generic names of the parents into a single word, while according to the International Rules they must be placed under one of the parent genera. Trigeneric hybrids are preferably designated by affixing the ending *ara* to a personal name. (See *Adamara, Linncara, Lowiara.*) The Horticultural Code consists of sixteen articles; the English version of it will be found in the Jour. Roy. Hort. Soc. 37:149–151 (October, 1911).

The International Rules have been adopted and are followed by nearly all botanists of the Old World and of this continent outside of the United States. In England there are perhaps a few who still follow the Kew rule, and an example of a very recent horticultural book in which this rule is adhered to is Bean's "Hardy Trees and Shrubs." In Germany there is one horticultural writer, A. Voss, who holds to the Paris Code as amended by O. Kuntze, as appears from his botanical contributions to the "Landlexikon" edited by K. von Putlitz & L. Meyer and in course of publication. In this country, a large number of botanists have adopted the International Rules, but the greater part follow the Philadelphia Code. The differences that the application of these codes produces on the nomenclature of our native plants may readily be seen by comparing the two manuals of the flora of northeastern North America, namely the seventh edition of Gray's Manual by Fernald and Robinson and the second edition of Britton's Manual; the first follows the International Rules the second the Philadelphia Code.

An interesting secession from the Philadelphia Code is constituted by E. L. Greene and two or three other botanists; they do not recognize any fixed starting point in botanical nomenclature and go back to Theophrastus, Dioscorides and Pliny, accepting the occasional binomial names found in the works of pre-Linnæan writers. They quote, e. g., *Populus nigra*, Pliny; *Hesperis hortensis*, C. Bauhin; *Rorella Cordi*, Lobelius (=*Drosera rotundifolia*); *Bucanephyllum americanum*, Plukenett (=*Sarracenia purpurea*); *Spiræa*, Theophrastus. Other examples may be found in articles published in the "American Midland Naturalist."

It is to be hoped that there will be no more secessions from the two chief nomenclatorial codes, but that instead the followers of these two codes will find, by mutual concessions, some common ground to agree on a universal code acceptable to all botanists of the world.

Alfred Rehder.

NANDÌNA (Japanese name). *Berberidàceæ*. A small, tender shrub with bright red or white berries, said to be cultivated in every little garden in Japan.

Erect plant: sts. about as thick as a finger: foliage evergreen, graceful at all times, twice or thrice ternately cut; lfts. entire: young growth prettily tinged with red, and the bases of the lower stalks often swollen into red globular bodies: fls. small, numerous, white and panicled. It agrees with the common barberries in having 6 stamens and an indehiscent berry, but the fls. are differently colored and the sepals more numerous. There are about 6 petals, but the numerous sepals gradually pass into petals, the outer ones being small, green and leathery, the inner larger and whiter: ovules 2, ascending from the base: berries red, in clusters terminating the branches, handsome.—Species 1, **N. doméstica**, Thunb. Japan and China. B.M. 1109. Gn. 23, p. 329; 58, p. 13. G.M. 51:665. G. 29:43.

This shrub is rarely grown North under glass. Pot-grown plants or seeds are procurable from Japanese dealers. The seeds are said to be of an uncommon shape, being convex on one side and concave on the other. Ernest Braunton writes as follows about the plant in California: "*Nandina domestica* is an old-time favorite in southern California, ultimately reaching to 8 feet in height, though of slow growth. For a few years past its use in local gardens has steadily increased and bids fair to rival that accorded it in Japan, where it is to be found in nearly every garden. It grows well in whole or partial shade and if well supplied with water does equally well in the hottest sunshine. If used in sunny position it will be found to thrive best when planted in lawns, evidently needing more atmospheric humidity than our climate naturally affords. Its terminal trusses of white flowers, followed by brilliant scarlet berries, added to a winter change of foliage from green to red, unite to make it an interesting and attractive shrub throughout the year." The plant is held in great reverence in China; it there withstands considerable frost when the wood is well ripened.

Wilhelm Miller.

NÁNNORHOPS (*dwarf bush*, because of its low stature). *Palmàceæ*. One tufted small fan-lvd. palm, Afghanistan and India, *N. Ritchieàna*, Wendl., scarcely cult. St. or rhizome prostrate, several feet long, branched: lvs. rigid, plicate, with whitish powder, the segms. curved and 2-lobed, the petiole unarmed (and thereby distinguished from *Chamærops humilis*): spadix much branched: spathes tubular and sheathing: fls. polygamous; corolla 3-parted; stamens 6–9: fr. a small globose or oblong 1-seeded drupe the size of a grape. G.C. III. 51:66.

In the mountains of Afghanistan it grows where covered with snow in winter. In sheltered places there it reaches a height of 15–25 ft.: lvs. 3 ft. long, the petiole half as long as the blade, the 8–15 lf.-divisions 1 ft. long. The hard bony seed is said to be surrounded with an edible pulp.

L. H. B.

NANÒDES (a *pigmy:* the plants are small). *Orchidàceæ*. Two or 3 epiphytic S. American orchids now referred to Epidendrum. In that genus it forms a section or subgenus, with lip adnate to column, and 4 pollen-masses on ovate glands. **E. Medùsæ,** Pfitz. (*Nanòdes Medùsæ*, Reichb. f.), from the Andes, is a very singular fleshy-stemmed pendent orchid with distichous imbricated, twisted glaucous lvs., and 2 or more large terminal fls. with greenish sepals and petals shaded dark brown, and a fringed dark purple lip: pseudobulb about 1 ft. long. B.M. 5723, where Hooker remarks: "Amongst the many bizarre fls. which Orchideæ present, few are more singular than this Nanodes, to which Mr. Reichenbach has most felicitously given the name of *Medusæ*. Altogether the flattened, stout culms, and the extraordinary appearance and lurid purple of the flower give it a most sinister appearance, and, for an orchid, a most unusual one."—**E. Máthewsii,** Reichb. f. (*Nanòdes Máthewsii*, Rolfe). Rhizome creeping, many-rooted: st. nearly erect: lvs. linear, acute, canaliculate at base, distichous: fl. single, large; sepals lance-acuminate; petals linear, acute; lip emarginate. Peru.

L. H. B.

NAPǼA (name refers to a *glade* or *dell*). *Malvàceæ*. One species, *N. dioìca*, Linn., a rough-pubescent perennial herb, 5–9 ft. high, st. nearly simple, growing in valleys and bottom-lands, Pa. to Minn. and Tenn., said to be sometimes cult. for ornament. The fls. are small, white, in terminal corymbs, diœcious, the staminate with 15–20 anthers and the fertile with sterile stamens and an 8–10-carpelled ovary; petals entire; calyx 5-toothed and no involucel: lvs. large, the radical ones often 1 ft. or more across, palmately 9–11-cleft and the lobes pinnatifid. This plant is not to be confounded with *Sida Napæa* (or properly *S. hermaphrodita*), of similar range and habit and said also to be cult. in old gardens, but which has hermaphrodite fls. See *Sida*.

NAPOLEÒNA (after Napoleon Bonaparte). *Lecythidàceæ*. A small but botanically remarkable genus of Trop. W. Afr., very little known in cult. and demanding no treatment here. The fls. are of interesting structure. They are shaped like a saucer, about 2 in. diam., and the dominant color is reddish and bluish. The petals, staminodia and stamens are in 4 concentric rows, and more or less joined at the base to form the saucer or cup; the petals, on the outside, are connate and form a circular membrane or rim with many folds: the staminodia, free or nearly so, form a second row; the third row of connate staminodia: inner row of good stamens also connate at base. In the Flora of Trop. Afr. the fls. are said to be red, white or blue. Elsewhere it is stated that the fls. turn bluish as they decay. The names and illustrations of the species are confused. The names met in horticultural literature are *N. imperiàlis*, Beauv., *N. Heudelòtii*, Juss., *N. Whítfieldii*, Lem., *N. Mánnii*, Miers, *N. cuspidàta*, Miers, *N. Mìersii*, Hook. f. In B.M. 7199, some of the synonomy of the species is explained, with references to figures.

NARCÍSSUS (name probably derived from the story of the youth Narcissus, in mythology). *Amaryllidàceæ.* Narcissus. Daffodil. Well known and desirable mostly spring-blooming bulbs, hardy and also used for forcing.

Plants with tunicated bulbs, from which arise the foliage and the fl.-scapes: lvs. linear or even subulate, usually appearing with the bloom: fls. white, yellow or seldom green, erect or pendent, solitary or umbellate on the top of the scape or peduncle, the spathe 1-lvd. and membranous; perianth salverform, the tube varying in shape, the 6 segms. equal or nearly so and ascending, spreading or reflexed, the throat bearing a corona or crown which is long and tubular (trumpet daffodils), or cup-shaped, or reduced to a ring; stamens 6, attached in the perianth-tube, the filaments short or long; ovary 3-celled, the style filiform and the small stigma 3-lobed: caps. membranous, loculicidal, bearing globose or angled seeds.—The species of Narcissus grow natively in Cent. Eu. and the Medit. region and eastward through Asia to China and Japan. Many species-names are in the literature, most of them representing variants or hybrids, for the plants are extensively cult. and have received much attention from fanciers; probably 25 or 30 species represent the original stocks. The prominent species-types from the horticultural point of view are *N. Pseudo-Narcissus* (the common daffodil), *N. Bulbocodium* (hoop-petticoat daffodil), *N. Tazetta* (polyanthus narcissus), *N. Jonquilla* (jonquil), *N. poeticus* (poet's narcissus).

2437. Narcissus Bulbocodium var. monophyllus. (×⅔)

It is customary to throw the cultivated narcissi into three main groups, founded on the length or size of the crown or cup in the perianth: I. The true daffodils or trumpets (Magnicoronati; Figs. 2437–2442), those with crowns equaling or surpassing the perianth-segments in length; here belong *N. Pseudo-Narcissus*, *N. Bulbocodium.* II. The star-narcissi or chalice-flowers (Mediocoronati; Figs. 2443–2446), with crowns about half the length of the segments, as *N. triandrus*, *N. incomparabilis.* III. The true narcissi (Parvicoronati; Figs. 2447–2450), in which the crown is very short or reduced to a rim, as *N. poeticus*, *N. Jonquilla* and *N. Tazetta.* With the introduction of hybrid races, this old and usual classification becomes confused. It is suggested, therefore, by S. Eugene Bourne, an English authority, in "The Garden," "that the first step to an improved classification—a step which requires a very slight alteration in the present system—should be to form group I exclusively of true daffodils, and group III exclusively of true narcissi. All seedlings resulting from the union of two true daffodils should be placed in group I, all those from the union of two true narcissi in group III. All cross-bred forms containing both true daffodil and true narcissus blood should be put with the two species of intermediate character, Triandrus and Juncifolius, in group II, to be called, perhaps, intermediate narcissi. In subdividing this middle group, forms having special characteristics must be carefully distinguished from each other (for example, hybrids of Triandrus from hybrids of Poeticus, and so on), but subject to such distinctions, arbitrary crown-perianth measurements would be usefully employed." Discarding, for the garden forms, the older grouping into the three crown-lengths, the Royal Horticultural Society recently adopted eleven groups of Narcissi, as follows (subdivisions omitted except in I):

I. Trumpet Daffodils. Trumpet or crown as long as or longer than the perianth-segments.
  Yellow.—Perianth and trumpet yellow.
  White.—Perianth and trumpet white.
  Bicolor.—Perianth white, trumpet yellow.
II. Incomparabilis. Cup or crown not less than one-third but less than equal to the length of the perianth-segments.
III. Barrii. Cup or crown less than one-third the length of the perianth-segments.
IV. Leedsii. Perianth white, and cup or crown white, cream or pale citron, sometimes tinged with pink or apricot; embracing different dimensions.
V. Triandrus Hybrids.
VI. Cyclamineus Hybrids.
VII. Jonquilla Hybrids.
VIII. Tazetta and Tazetta Hybrids.
  Poetaz.—Hybrids between Poeticus and Polyanthus sorts.
IX. Poeticus Varieties.
X. Double Varieties.
XI. Various. To include *N. Bulbocodium*, *N. cyclamineus*, *N. triandrus*, *N. juncifolius*, *N. Jonquilla*, *N. Tazetta* (sp.), *N. viridiflorus*, etc.

In the present account, it is desired to keep the type-species in view, and therefore a botanical classification is followed. In this systematic treatment, use has been made of Bourne's "Book of the Daffodil," although it is founded on Baker's "Handbook of the Amaryllideæ." A "Key to the Daffodils" by Wilhelm Miller and Leonard Barron in Kirby's "Daffodils, Narcissus and How to Grow Them," New York, 1907, arranges the species and the main garden races. In this systematic account, only the main types or well-recognized races are described; other forms will be found in the supplementary list at the end of the article.

Into the second or medium-crowned group may be placed a number of good and popular horticultural strains which are actually or presumably hybrids between long-crowns (or trumpets) and short-crowns. Very likely *N. incomparabilis* and *N. odorus* are themselves hybrid series. Forms of *N. triandrus* might very well be classed with the long-crowns. The other garden series in this group are undoubtedly of hybrid origin, as: *N. Barrii* (Fig. 2446) had yielded about fifty named forms when Baker wrote in 1888. It is one-flowered: perianth-segments spreading, somewhat imbricated, to 1¼ inches long, sulfur-yellow, twice or more the length of the crown, the latter somewhat expanded, yellow and more or less margined with darker yellow or red. *N. Leedsii* is one-flowered: flowers slightly drooping, with spreading milk-white segments twice or more the length of cup-shaped very pale yellow crown, which usually changes to white. Other group-series, as *N. Humei*, *N. tridymus*, *N. Backhousei*, will be found in the supplementary list (page 2113).

The narcissi are among the most popular of all spring-flowering plants, being mostly hardy, free-blooming and showy, and of interesting forms and colors There are a few autumn-bloomers in the genus, but these are little known horticulturally. They are *N. viridiflorus*, *N. serotinus* and *N. elegans*. The hybrid narcissi have now introduced many forms, and races of varieties, and the nomenclature is mixed; but these forms and tribes add greatly to the resources of the cultivator. In this country, there is less amateur interest in the group than in European countries, although some of the kinds are forced in great quantities and many of them are widely popular among planters.

Narcissus has an interesting literature. Some of the older standard works in English are Burbidge's "The Narcissus," with many colored plates, and Peter Barr's "Ye Narcissus or Daffodyl Flowre, and hys Roots." Haworth wrote a monograph of narcissi in 1831, in which he made sixteen genera of the plants that are now referred to Narcissus. For 300 years and more, some of the species have been known as cultivated plants, and the literature runs through all the gardening books and periodicals. The number of good illustrations is also very large; some of the available portraits of the species and varieties in recent periodical literature are indicated in the systematic account herewith under the names that they bear in the journals. Some of the pictures used in this article are adapted from G.F. 5:209–13.

Usual outdoor culture of Narcissus. (J. N. Gerard.)

The narcissi are among the oldest of cultivated plants, but were much neglected for many years. Within the last twenty-five to thirty years there has spread a renewed interest in the group, with the usual result in such cases that the habitats have been closely searched for new forms, and hybrids have been raised till we have now a surprising number of beautiful flowers. Recently many of these have become so plentiful that they are within reach of the most impecunious gardener, and there is no reason why American gardens should not be filled with good collections of these beautiful flowers, or why florists should not force a more interesting list.

With few exceptions, the narcissi are hardy and strong-growing under ordinary cultivation. The "bunch-flowered" or polyanthus narcissi (*N. Tazetta*) and corbularias (*N. Bulbocodium*) are better grown under glass. The moschatus varieties, which are white (or properly sulfur-white) forms, seem to be of rather tender constitution in most gardens. Otherwise the narcissi as a rule succeed in good turfy loam, but no manure, rotted or otherwise, must touch the bulbs. Of course drainage should be good, and moisture plentiful in the growing season. In the garden it is well to plant very strong bulbs say 6 or 8 inches deep, and 3 inches at most apart, and allow them to remain till they form strong groups, or until they show signs of too much exhaustion from numerous offsets. Weak or small bulbs should not go so deep. It is advised to cover the bulbs once and one-half their own depth or size, measuring the solid body part of the bulb and not the soft neck or top. They may be placed a little deeper in light soils. The large bulbs may be 4 to 6 inches apart, and the smaller ones 3 to 4 inches. As decaying foliage is unsightly in the garden, a good plan is to dress the beds in the fall with rich manure, either animal or chemical, and in early spring start seedlings of annuals to cover the beds when the narcissi are through flowering, the dressing being necessary for the sustenance of the double crop. Too strong cultivation of the narcissi is not to be recommended, an extra vigor of growth being detrimental to the purity of the color of the flowers. If the object is to increase one's stock as quickly as possible, biennial or even annual lifting and separation of bulbs is advantageous. For naturalizing in waste places, in the grass, or near water, many of the strong-growing kinds will succeed perfectly.

The proper time to plant is in late summer or early autumn, and the poeticus kinds should not be kept out of ground longer than possible. Knob-like excrescences at the base of the bulbs indicate that growth is beginning and that planting should not be delayed. Partial shade, or at least protection from midday sun, is desirable, as the blooms last longer, and the colors are likely to be better. The old-fashioned or unimproved kinds will last for many years, but the more highly developed strains may need renewal every three or four years.

A most satisfactory planting of narcissi for house decoration is the use of flat lily pots, say 8 inches in diameter, placing the bulbs close together. The flowers carry best and keep better if cut when half open.

The intending collector will perhaps be confused when he opens a list of say 200 varieties, and it may be as well to say that a moderate beginning may be made by choosing a few of each section into which these are usually divided in good lists, bearing in mind that price is not an indication of the beauty or usefulness. As a matter of fact, the lower price is usually an indication that these are not uncertain and are probably more valuable in the garden.

2438. Narcissus Pseudo-Narcissus. (×⅓)

Narcissi for naturalizing and bedding. (David Lumsden.)

Many attempts have been made to naturalize the narcissi in this country. Often, however, very little success has been achieved. The difficulties are due in a measure, first, to climatic conditions, the very dry summer weather being apparently detrimental to their growth; second, the cultural treatment afforded the plants. The former can be overcome to a considerable degree by planting the bulbs in a cool sheltered position where they will not be exposed to the prevailing dry winds. The latter difficulty can be remedied by changing cultural methods. Frequently the bulbs are placed in a lawn, and as soon as their flowering period is over the foliage is cut down to the ground. This practice is to be condemned as it seriously impairs the vitality of the plants, and in a comparatively few years they succumb. When naturalization of bulbs in the grass is desired, a part of the estate or grounds should be taken where the grass may remain unclipped until the ripening period of the bulbs approaches. This period is readily discernible, as the foliage will develop a yellow hue and wither. It is then that the grass may be mown and the bulbs will suffer no injury.

In colonizing narcissi bulbs, it is advisable to plant early in autumn or as soon as the bulbs are received, which is usually the month of October. The bulbs should be set 4 to 6 inches deep, the larger sorts 5 to 6 inches apart; and the smaller species and varieties 3 to 4 inches apart. The plants may be massed by the side of ponds or streams, along sides of shady, or partially shady, walks. Planting in open, bleak, and especially in windy situations, should be avoided. Under trees, the bulbs are likely to be short-lived unless they are well supplied with moisture and available food.

Bedding.—The daffodil lends itself admirably to formal bedding work, and it is especially attractive when planted in combination with other bulbous or spring-bedding plants, such as *Scilla sibirica* or *Myosotis scorpioides*, the blue flowers of the scillas or myosotis making an attractive groundwork in contrast with the golden yellow trumpets of the daffodils. The daffodil also stands cold weather well and will recuperate after being subjected to a late spring freeze, showing no apparent sign of injury.

List of narcissi arranged in order for successional blooming in beds, border and garden.

By careful selection, narcissi may be had in bloom from the early part of April through the month of May. Some allowance must be made for abnormal seasons, late planting and uncongenial soils. In the following list, arrangement is made according to the order of earliness. The narcissus season in the northern states is April and May. Species and varieties marked (a) are early flowering; (b) second early; (c) intermediate; (d) late; (e) very late.

Section I. Large Trumpet Class.

(a) *Narcissus Pseudo-Narcissus* (Lent lily).

minimus
princeps
tortuosus
Golden Spur
obvallaris (Tenby daffodil)
Henry Irving

(b) *Narcissus Pseudo-Narcissus.*

Horsfieldii

Patellaris
King Edward VII
ornatus

Section IV. Poeticus-Tazetta Class (Poetaz).

(d) *Narcissus poetaz.*

Alsace
Ideal
Aspasia
Irene
Elvira
Klondyke

The forcing of narcissi under glass. (David Lumsden.)

Of late years the forcing of narcissi under glass has assumed immense proportions. Tens of thousands of these bulbs are forced annually by many of the larger florists' establishments in this country. With few exceptions, these bulbs are imported, France and Holland supplying the major part. The earlier species, such as *Narcissus Pseudo-Narcissus* var. *obvallaris* (trumpet), *N. Pseudo-Narcissus* var. *spurius*, Golden Spur, and *N. Tazetta* var. *papyraceus* (paper-white narcissus), are received from France and arrive early in August, while the larger importations of the various species are received from Holland the latter part of September. The French bulbs therefore give the earlier bloom.

When the bulbs arrive, they should at once be placed in the pots or boxes in which they are to be grown. Immediate potting is a necessity, as the flowering quality of a bulb is greatly impaired if it is kept out of the soil any great length of time. This is especially true if the bulb is exposed to the influence of a dry warm office or storeroom. If the bulbs are to be grown for home or conservatory decoration, a pot or pan, preferably 6 to 8 inches in diameter, is used, five to nine bulbs being placed in each, according to the size of the bulbs. If grown in boxes for cut-flowers, 24 by 12 by 3 inches is a convenient size to handle.

The soil should be rich and composed of two-thirds good garden loam and one-third leaf-mold or well-decayed stable-manure, with an admixture of sand sufficient to keep the compost open. The pots should be well drained with crocks or cinders, and the soil pressed firmly around the bulbs, leaving the tips just visible. Allow ½ inch of space between the top of the soil and the top of the pot to insure that the plants are well watered when being forced. When the bulbs are potted they should be placed close together in a cold-pit or frame and given a thorough watering, covering them at once with 5 or 6 inches of screened cinders or sand, which acts as a non-conductor. The object of this is to keep them from drying out, and at the same time to maintain a low temperature which will induce them to develop good root-action. Before removing any bulbs from the coldframe or pit to the forcing-house, it is imperative that they be well rooted, as many of the failures in bulb-forcing are due to disregard of this essential precaution. A temperature of 55° to 60° F. at night in the forcing-house will be adequate. It will require four to six weeks' forcing to bring the bulbs into flower, depending in a measure on the season and the varieties forced.

Bulbs of the hardy narcissi which have not been unduly forced, may be planted outside when the ground is in condition in spring. These bulbs will yield a display of flowers in the garden the second year after forcing, and continue for years if the conditions are right.

The following species and varieties are among the most useful for forcing:

N. Tazetta var. *papyraceus* (paper-white narcissus) is the most useful of the florists' narcissi. Its pure white flowers are of great value to the trade. It is one of the easiest to force and the first to appear on the market.

N. Pseudo-Narcissus var. Van Sion (double daffodil) is grown both in boxes for cut-flowers, and in bulb-pans and pots to be used for conservatory and home decoration. Not being adapted to early forcing, the first batch of plants should not be brought into the forcing-house before the end of December or early January.

Narcissus Pseudo-Narcissus var. *obvallaris major* (Tenby daffodil), *N. Pseudo-Narcissus* var. Golden Spur, *N. Pseudo-Narcissus* var. Princeps, Emperor, Empress, and King Alfred, *N. incomparabilis* var. Sir Watkin, *N. Leedsii* var. Duchess of Westminster, *N. Barrii* var. *conspicuus*, *N. Jonquilla*, *N. Tazetta*, *N. poeticus* and *N. poeticus* var. *patellaris* are all desirable forms. For very early forcing, *Narcissus Pseudo-Narcissus* var. *obvallaris*, *N. Pseudo-Narcissus* var. Golden Spur, and *N. Tazetta* var. *papyraceus* are most

LXX. Narcissus poeticus.—The poet's narcissus; hardy and good.

largely grown. Only first-class bulbs should be used for forcing purposes. Bulbs potted early in September will be well rooted by the middle of October, at which time some of the earliest narcissi may be placed in the forcing-house; and by bringing in a batch each week, a continuous display of flowers may be had from November until Easter. For the best results in forcing bulbs, the night temperature should not exceed 60° F.

Growing bulbs in water on pebbles.—Recently much interest has been taken in growing narcissus bulbs in vessels containing water and pebbles. The culture is simple, and such bulbs may be readily grown under dwelling-house conditions. The bulbs should be placed in shallow jardinieres or saucers with clean white pebbles arranged around them to keep them in position and to hold them up. The jardinieres should be kept supplied with water sufficient to keep the roots submerged. *Narcissus Tazetta* var. *papyraceus* (paper-white narcissus) and *N. Tazetta* var. *orientalis* (Chinese sacred lily) are the most popular and useful for this purpose.

A. MAGNICORONATI *or* LARGE-CROWNED *species: corona or crown as long as the segms. or even longer, trumpet-shaped or cylindrical.*—DAFFODILS. (*Forms of No. 4 may be sought here.*)

B. *Lvs. green, few (often only 1), very slender and nearly terete, channelled.*

1. **Bulbocòdium,** Linn. (*Corbulària* species). HOOP-PETTICOAT DAFFODIL. A slender small plant, with bulb 1 in. or less in diam., and the very slender lvs. (usually 3 or 4 to each st.) mostly overtopping the blossoms: fl. 1, ascending or horizontal (not declined), 1½ or 1¾ in. long in most forms, normally bright yellow in all parts, the very prominent thin flaring corona entire or crenulate; perianth-segms. very narrow, ascending, to ¾in. long, the keel green, the same color as crown; stamens inserted near the base of the tube, declined, rather long. S. France to Morocco. May. B.M. 88. J.H. III. 54:393. Gn. 69, p. 222. G. 5:131.—Runs into many garden forms and hybrids. Fls. usually borne 5–8 in. above the ground. Minor forms are var. *conspicua*, a large yellow kind, 6 in.; var. *præcox*, large, yellow, early-flowering, 6 in.; var. *tenuifòlia*, small, early-flowering, golden yellow, 3 in.

Var. **Graéllsii,** Baker (*N. Graéllsii*, Webb). Lvs. about 2: perianth about 1 in. long, whitish or primrose-yellow. Castile. B.M. 6473 B.

Var. **monophýllus,** Baker (*N. monophýllus*, Moore. *N. Clùsii*, Dunal. *Corbulària monophýlla*, Dur.). Fig. 2437. An Algerian form, winter-blooming, usually with 1 lf., and fl. sessile and white: corona crenate. B.M. 5831. Gn. 60, p. 199; 76, p. 94. J.H. III. 42:287.

Var. **citrìnus,** Baker. Fls. large, 1–2 in. long, pale lemon-yellow or sulfur-yellow, the corona somewhat crenulate and 1 in. diam.; stamens and style included. Gn. 78, p. 189.

Var. **nivàlis,** Baker (*N. nivàlis*, Graells). Lvs. 2–3, erect and slender, the scape 2–4 in. long: perianth orange-yellow, ¾in. or less long; style and stamens exserted. Spain.

BB. *Lvs. glaucous, several, flat.*

C. *Segms. of perianth spreading horizontally.*

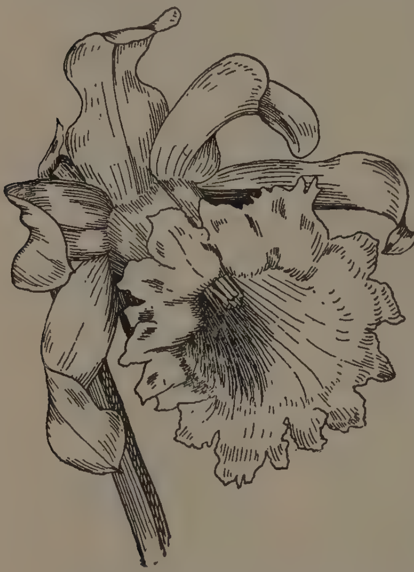
2. **Pseùdo-Narcíssus,** Linn. (*Ájax Pseùdo-Narcíssus*, Haw.). COMMON DAFFODIL. TRUMPET DAFFODIL. LENT LILY. Fig. 2438. Strong plant, 12–18 in. tall, with bulb 1½–2 in. and more diam.: lvs. 4–6, glaucous, narrow but flat, erect, usually about reaching the blossoms: fl. about 2 in. long, horizontal or ascending, pale yellow, the segms. and corona usually of different shades, the corona deeply crenate or almost crenate-fimbriate, more or less plicate; stamens inserted near the base of the perianth, much shorter than crown; style little longer than stamens. From Sweden and England to Spain and Austria.—Exceedingly variable in size, shape and coloring of fls. There are full double forms (common daffodil) in which the corona disappears as a separate body, and supernumerary segms. are present. This is one of the hardiest and commonest of narcissi.

2439. Cernuus—a form of N. Pseudo-Narcissus var. moschatus. (×⅔)

This species is the Trumpet narcissus, so named from the long corona. The Ajax daffodils are of this species and its derivatives, separated by Salisbury, Haworth and others as a distinct genus (*Ajax*). The normal forms are Yellow Trumpets, but the Bicolor Trumpet, var. **bícolor,** Baker (*N. bícolor*, Linn.), has pure white, spreading and much imbricated segms. and yellow corona. To this variety Baker refers *Ájax bréviflos*, Haw. (B.M. 1187), and *Hórsfieldii*, Burb. Horsfield and Empress are trade forms belonging in this group, the former being the earlier of the two. The White Trumpets are var. **moschàtus,** Baker (*N. moschàtus*, Linn.; B.M. 1300), which has cream-white or white fls., the perianth-tube obconic and nearly as broad as long, the segms. more or less ascending, twisted, sulfur-tinged and becoming pure white, crown about as long as segms., the throat crenate-plicate and about 1 in. across. Gn. 78, p. 89. J.H. III. 60:443. G. 28:231; 36:192. To this set, Baker refers *N. candidíssimus*, Red., *N. longiflòrus*, Salisb. (B.M. 924), with twisted segms. shorter than crown; *Ájax álbicans*, Haw., with large fl. and more imbricated segms.; *A. cérnuus*, Haw., with a more drooping fl. and tube longer than broad, the segms. sometimes longer than crown. The *cernuus* of the trade (Fig. 2439) has segms. equaling and sometimes exceeding the trumpet.

Other main forms or types of *N. Pseudo-Narcissus* are var. **màjor,** Baker, to which Baker refers *N. hispanicus*, Gouan, *Ajax propinquus*, Haw., *A. maximus*, Haw., *A. spurius*, Haw., *A. Telamonius*, Haw., *A. lorifolius*, Haw., and others. More robust and larger than the type of *N. Pseudo-Narcissus*, the fls. 2–2½ in. long, tube obconic, long and broad, segms. mostly spreading not imbricated and lemon-yellow; crown same length and shade as segms., and with a much crisped margin. B.M. 51; 1301. Spurius of the trade belongs here, with a hooded perianth and trumpet wide open at mouth; Golden Spur and Henry Irving are forms of it. The garden form *maximus* (Fig. 2440) has a very large fl., deep golden yellow, segms. twisted at ends, crown with spreading limb. G. 6:505; 25:132 (as *maximus superbus*); 28:145. J.H. III. 43:274. *Obvallàris*, Hort. (Tenby daffodil) is a sub-variety of var. *major*. It is a distinct form of medium size, somewhat dwarf, very floriferous, almost self-yellow, the perianth wheel-like with rather short segms. Gn. 63, p. 245. Var. **mìnor,** Baker (*N. mìnor*, Linn. *Àjax mínimus*, Haw.), is much smaller in all its parts than the type of *N. Pseudo-Narcissus;* lvs. 3–4 in. long and ¼in. broad: fls. to 1¼ in. long, with obconic tube and oblong sulfur-yellow segms.; crown deeper yellow, with deeply 6-lobed spreading throat. The garden *minimus* (Fig. 2441) is very small in all ways; said to be the smallest and earliest Trumpet narcissus. Gn. 76, p. 563. G. 36:171. Var. **mùticus,** Baker (*Àjax mùticus*, Gay). General stature of *N. Pseudo-Narcissus*, with somewhat broader lvs.: fl. to 1½ in. long, with obconic tube and sulfur-yellow segms.; crown deep lemon-yellow, as long as segms., ¾in. diam., the throat very truncate: from the Pyrenees. Gn.W. 5:593. Var. **Jóhnstonii,** Baker (*N. Jóhnstonii*, Hort.), is described by Baker as "a Portuguese form with a tube ¾in. long, ⅓in. broad at the throat, a pale truncate corona, and style much longer than the stamens." Bourne calls *N. Johnstonii* "a typical hybrid. Found wild in Portugal (Pseudo-Narcissus × triandrus). Slightly variable in form. In color from soft sulfur to pale lemon. Long straight, funnel-shaped corona; perianth-segms. somewhat reflexed. Is best grown in grass or coldframes."

According to Bourne, "the recognized type fl. of *N. Pseudo-Narcissus* is the wild daffodil of England. Trumpet yellow; perianth-segms. pale sulphur." White varieties are found wild here and there in England. There are many hybrids and intermediate forms with Latin names. See supplementary list, page 2113.

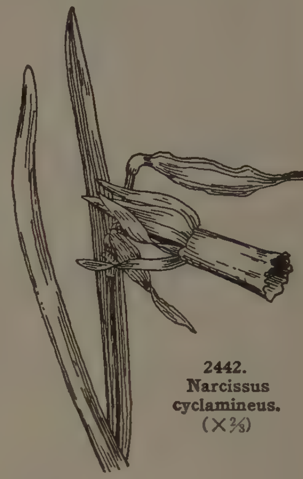


2440. Narcissus maximus.—A form of N. Pseudo-Narcissus. (×⅔)

2441. Narcissus minimus.—A form of N. Pseudo-Narcissus. (×⅔)

cc. *Segms. reflexed or pointing backward.*

3. **cyclamíneus,** Baker (*Àjax cyclamíneus*, Haw. *N. Pseùdo-Narcíssus* var. *cyclamíneus* Baker). Fig 2442. Lvs. narrow and linear, deeply grooved, the scape slender and subterete: fl. very drooping, the tube obconic and very short, the segms. lemon-yellow, ¼in. broad, abruptly reflexed (hence *cyclamineus*, or cyclamen-like); crown equaling the segms., orange-yellow, crenate. Portugal. B. M. 6950. Gn. 59, p. 352; 69, p. 148; 71, p. 252. J.H. III. 42:287; 64:305.



2442. Narcissus cyclamineus. (×⅔)

AA. MEDIOCORONATI *or* MEDIUM-CROWNED *species: corona or crown usually about half the length of the segms., cup-shaped. (Forms of N. triandrus may have large crowns.)*

B. *Segms. narrow, standing straight backwards (reflexed).*

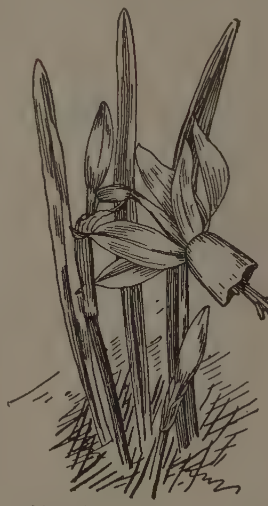
4. **triándrus,** Linn. (*Ganymèdes álbus*, Haw.). Fig. 2443. Slender most dwarf rush-lvd. species (scape 10–15 in. tall), bulb ¾in. or less diam.: lvs. few (2–4), very slender and semi-cylindrical and not overtopping the blossoms, channeled: scape very slender, semi-cylindrical: fls. 1 to several, horizontal or drooping, an inch long, but variable in size, both the lanceolate sharply-reflexed segms. and the entire cup-shaped corona (which is half as long as segms.) pure white in the type; stamens sometimes a little exserted. Spain and Portugal. G. 17:114; 19:355.—There are several forms, as var. *cóncolor*, Hort. (*Ganymèdes cóncolor*, Haw.), pale self-yellow; var. *pallídulus*, Hort. (*N. pallídulus*, Graells), primrose-yellow. B.M. 6473 *A;* var. *pulchéllus*, Hort. (*Ganymèdes pulchéllus*, Haw.), segms. yellow, corona white. B.M. 1262. (as var. *luteus*). Gn. 75, p. 604; var. *nùtans*, Hort. (*Ganymèdes nùtans*, Haw. *N. trílobus*. B.M. 945), corona a deeper yellow than the segms., crenulate.

Var. **calathìnus,** Hort. (*N. calathìnus*, Red., Burbidge, not Ker). Crown or corona larger, nearly, or quite as long as the segms., the fl. pale yellow. Isl. of Brittany. Gn. W. 20:297. Gn. 77, p. 459.

BB. *Segms. oblong or broader, spreading.*

c. *Foliage glaucous,*

5. **incomparábilis,** Mill. (*N. Gouáni*, Red. *Quéltia fœtida*, Herb.). Fig. 2444. Strong fine ornamental plant, with large bulb (1½ in. diam.) and 3–5 lvs.: lvs. flat (but narrow) and glaucous, nearly or quite the length (1 ft. or more long) of the distinctly 2-edged scape: fl. always 1, not fragrant, horizontal or



2443. Narcissus triandrus. (×⅔)

somewhat ascending, on a very short pedicel, the tube usually greenish, and subcylindrical, the segms. and crenate-plicate 6-lobed corona pale yellow in the type (but varying to other color combinations), the stamens and style not exserted. S. France and Spain to the Tyrol; by some considered a hybrid race of *N. Pseudo-Narcissus* × *N. poeticus*. B.M. 121. G. 4:127.—One of the commonest species in cult., the fls. often 3–4 in. across, and in many varieties. Double forms are frequent. Var. **álbus,** Hort., has white fls., with the corona usually pale yellowish. Var. **aurántus,** Hort., has the corona orange at the top.

2444. Narcissus incomparabilis. (×⅔)

cc. *Foliage green.*

6. **odòrus,** Linn. (*N. calathìnus,* Ker. *Philógyne odòra,* Haw. *N. Campernéllii,* Hort.). Campernelle Jonquil. Lvs. half the width (¼in.) of those of *N. incomparabilis,* the bulb nearly or quite as large, the peduncle subterete: fls. about 2 (sometimes 4), fragrant, the tube more slender than in *N. incomparabilis,* and the obconic shortly 6-lobed crenate corona somewhat smaller, the fl. bright yellow throughout; segms. obovate-oblong, cuneate below, spreading and not imbricated, to 1¼ in. long; style exceeding the anthers and reaching about half way of the crown. France and Spain and eastward; although found wild, by some regarded as a hybrid of *N. Jonquilla* × *N. Pseudo-Narcissus.* B.M. 934.—A good hardy species, differing from *N. incomparabilis* chiefly in its narrow lvs., 2 or more blossoms to a peduncle, fls. fragrant. Var. **trìlobus,** Baker (*N. trìlobus,* Linn., *N. lætus,* Salisb. *N. odòrus* var. *lætus,* Hort. *Philógyne heminàlis,* Haw.). Fls. smaller, the segms. about ¾in. long and imbricated; crown lobed, much shorter than segms. B.M. 78. Var. **mìnor,** Burb., fls. 1 in. diam. and the crown very small. Var. **rugulòsus,** Hort. (*Philógyne rugulòsa,* Burb.), has shorter oblong imbricated perianth-segms. Queen Anne's Jonquils are double forms of *N. odorus.*

7. **juncifòlius,** Lag. (*N. Requiénii,* Roem. *Quéltia juncifòlia,* Herb. *Philógyne mìnor,* Haw.). Very small slender species, with bulb about ½in. diam., and very narrow rush-like terete lvs., about 6 in. long: scape slender and terete, 6–12 in. long: fls. 1–4, horizontal or ascending, the tube slender-cylindrical (½in. long), the ovate spreading imbricated segms. and the cup-shaped, crenulate corona bright yellow or the corona sometimes darker; style reaching the throat of the tube; segms. about twice as long as corona. S. France and south.—A choice fancier's plant. Var. **minutiflòrus,** Baker (*N. minutiflòrus,* Willk.), has about 4 very small fls., the perianth-tube ⅓in. and the ovate segms. ⅙ in. long; corona truncate. Var. **rupícolus,** Baker (*N. rupícolus,* Dufour), Fig. 2445, has pedicels none or very short, perianth-tube ¾in. long and limb ¾in. across; corona 6-lobed. B.M. 6473 C. Var. **gaditànus,** Baker (*N. gaditànus,* Boiss.). Fls. 4 or 5, with rather long pedicels; segms. of perianth ⅙in. or less long, broadly ovate; corona truncate, nearly equaling segms.

2445. Narcissus rupicolus.—A form of N. juncifolius. (×⅔)

2446. Narcissus Barrii. (×⅔)

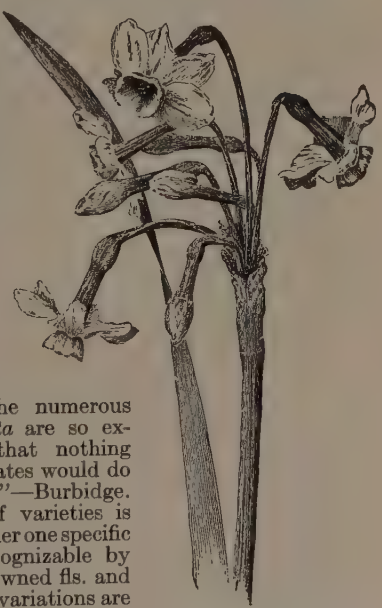
In this medium-crowned section belong many hybrid races derived from the long-crowns (or trumpets) and the short-crowns. Perhaps the best-known of these races in gardens are those called *N. Barrii* (Fig. 2446) and *N. Leedsii* (see pp. 2106 and 2113).

aaa. Parvicoronati *or* Small-crowned *species: corona usually much less than half the length of the segms., mostly saucer-shaped.*

b. *Corona soft and uniform in texture: lvs. various.*

c. *Lvs. ½in. or more broad, flat, mostly somewhat glaucous.*

8. **Tazétta,** Linn. Polyanthus Narcissus. Fig. 2447. Strong variable species, the bulb often 2 in. diam., the 4–6 lvs. 1½ ft. or less long, about the length of the flattened peduncle: fls. several (4–8 or 12), horizontal or declined on slender pedicels, the tube less than 1 in. long and greenish, the spreading obovate imbricate segms. pure white, and entire cup-shaped corona lemon-yellow, the whole fl. about 1½ in. across; stamens and style barely exserted. Canary Isls. to China and Japan.—Perhaps the commonest species and very variable. "Of the multiform Tazetta narcissi about 100 have received specific names."—Baker. In his monograph, he describes 14 subspecies, named in italic below. "The numerous forms of *N. Tazetta* are so extremely variable that nothing short of 50 folio plates would do the plant justice."—Burbidge. All this wealth of varieties is readily grouped under one specific type, which is recognizable by the many small-crowned fls. and the broad lvs. The variations are largely in color and in size of fls. Baker makes three groups:



2447. Polyanthus narcissus.—N. Tazetta. (×⅓)

(*a*) *bicolores*, the perianth white and the corona yellow. Here are to be placed *lacticolor, corcyrensis, patulus, ochroleucus* and many others.

(*b*) *albæ*, entire fl. white. Here belongs the "Paper White" (var. *papyràceus*, Hort. *N. papyràceus*, Ker. B.M. 947) very popular for winter bloom. G. 26:137. Here are to be referred the names *Panizzianus, dubius, canariensis, pachybolbos, polyanthos.*

2448. Jonquil.—Narcissus Jonquilla. (×½)

(c) *luteæ*, entire fl. yellow. Here belong *aureus, cupularis, Bertolonii, italicus.*

Var. **orientàlis,** Hort. (*N. orientàlis*, Linn. *Quéltia orientàlis*, Salisb.). Chinese Sacred Lily. Considered by Baker and others to be probably a hybrid between *N. incomparabilis* and *N. Tazetta:* robust: lvs. flat and green, ⅓in. broad: scape much compressed: fls. 3–4, on long erect or curving pedicels: tube of perianth subcylindrical, ½in. long and green, the segms. oblong, acute, sulfur-yellow, 1 in. long and half as wide; corona cup-shaped, one-third length of segms., orange-yellow, irregularly 3-lobed with erect margin; stamens and style not exserted. B.M. 948.—Grown in bowls of water; very fragrant.

N. pòetaz, Hort., is a hybrid race, from *N. Tazetta* × a form (*ornatus*) of *N. poeticus*. It is a promising race, with several poeticus-like fls. on the scape, the fragrance less cloying than that of *N. Tazetta.* They force readily. Writing of the origin and characteristics of the poetaz section, Joseph Jacob says in The Garden that they originated in 1885 in the bulb-fields of R. van der Schoot & Son, at Hillegom, Holland, from *N. ornatus* used as seed parent crossed with different kinds of *N. Tazetta.* "In their general appearance, this new race partakes of the characters of both parents. The Poet shows itself in the larger fls. and in some of the cups, while the Tazetta appears in their having several fls. upon one st. To sum up, they may be described as a large-fld. Polyanthus narcissus having from 2–6 blooms on a st., more pleasantly scented, and, generally speaking, with a looser and more artistic perianth." The *Poetico-Tazetta* narcissi are of this group or race.

cc. *Lvs. ¼in. or less broad, mostly terete or subterete, not glaucous.*

9. **intermèdius,** Lois. A yellow-fld. species, thought by some to be a hybrid between *N. Tazetta* and *N. Jonquilla*, distinguished from *N. Tazetta* chiefly by its subterete deep-channeled green lvs., which are only ¼in. wide: scape nearly terete: fls. 4–10; crown one-fourth or less the length of the oblong slightly imbricated spreading perianth-segms.; fls. soft yellow, the segms. described as lemon-yellow and the corona as orange-yellow: except for the subcylindrical green lvs. it might be taken for a form of the yellow race of Tazettas. S. France and Spain. Var. **primúlinus,** Hort. (*Hérmione primúlina*, Haw.), has imbricated segms. and the corona or crown with a 6-lobed spreading margin. B.M. 1299. Var. **bífrons,** Hort., has narrow perianth-segms. and deep crown.

10. **grácilis,** Sabine. Smaller, rush-lvd., 1 ft. high, the scape slender and weak and subterete, 1 ft. long: lvs. bright green, ⅙in. or less wide and very convex on the back: fl. pale yellow, the corona usually somewhat deeper colored than the oblong acute imbricated segms.; stamens and style not exserted. S. France probably, but known chiefly as an old garden plant, and perhaps, a hybrid of *N. Jonquilla* × *N. Tazetta* or *N. juncifolius* × *N. Tazetta.* B.R. 816. Var. **ténuior,** Hort. (*N. ténuior*, Curt.), the "silver jonquil," is more slender in all parts, the paler fls. changing to white. B.M. 379.

11. **Jonquílla,** Linn. Jonquil. Fig. 2448. Very slender and graceful hardy plant, 1½ ft. or less tall, the lvs. and subterete scape about equal in height: lvs. glossy dark green and very narrow and rush-like, 2–4 to a st.: fls. 2–6, fragrant, the slender cylindrical tube greenish yellow and 1 in. or less long; segms. yellow, obovate and scarcely overlapping; corona very short (⅛in. or less long), crenate, cup-shaped, the same color as the segms.; stamens and style barely exserted. S. Eu. and Algeria. B.M. 15.—One of the old-fashioned fls., perfectly hardy in N. Y. There is a double-fld. form. Var. *mìnor*, Baker (*N. Wébbii*, Parl. *Jonquílla mìnor*, Haw.), is a dwarf form: lvs. very slender: perianth-limb ½in. diam. Var. *stellàris*, Baker. Segms. lanceolate, reflexing; crown 6-lobed. Var. *jonquilloìdes*, Baker (*N. jonquilloìdes*, Willk.). Tube of perianth ½in. long, the limb ¾in. diam., the segms. obovate and imbricated; crown more than half as long as segms., the throat plain.

BB. *Corona with a prominently hardened or dry rim: lvs. broad.*

12. **biflòrus,** Curt. Primrose Peerless. Strong fragrant-fld. species, with globose bulb 2 in. or less in diam.: lvs. about 4 to a st., 1–2 ft. long and nearly or quite ½in. broad, and slightly glaucous, channeled, usually equaling and sometimes exceeding the stout 2-edged scape or peduncle: fls. 1–3, usually 2, white, with a pale yellow cup, the tube greenish white and 1 in. long, the segms. milky white, broad-obovate and over-lapping; the corona pale yellow, ⅛in. long, with a crisped scariose erect edge; stamens and style barely exserted. S. Eu. B.M. 197. G. 13:55; 27:295.—This plant has a wide range in the wild state, but some persons regard it as a hybrid of *N. Tazetta* and *N. poeticus.* Apparently little known in this country. Var. *álbus*, Hort., has white fls.

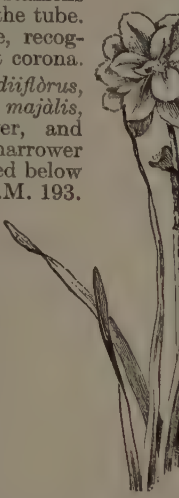
13. **poéticus,** Linn. Poet's Narcissus. Pheasant's Eye. Fig. 2449. A beautiful and popular strong-growing and hardy species, 1½ ft. high, the bulb 1 in. or more thick: scape or peduncle as long as the lvs., 2-

2449. Narcissus poeticus. (×¼)

edged: lvs. about 4 to a st., linear, ⅙in. broad, somewhat glaucous: fls. solitary (rarely 2), fragrant, horizontal, wide open, the obovate overlapping segms. white, about 1 in. long in native plants; corona much crisped and red-edged, ⅙in. or less long; tube of perianth cylindrical, greenish, 1 in. long; stamens and style barely exserted from the tube. Medit. region.—An old favorite, recognized by the red-margined short corona.

Var. **radiiflòrus,** Burb. (*N. radiiflòrus,* Salisb. *N. angustifòlius* and *N. majàlis,* Curt.). Slender; lvs. narrower, and shorter than the scape: corona narrower and more erect; segms. narrowed below so that they do not overlap. B.M. 193. An early-fld. form, often known as var. *angustifòlius.* Var. **ornàtus,** Hort. (*N. ornàtus,* Haw.) is an early-flowering kind, distinct in its perfect form: segms. of good substance, imbricated, broad and rounded. Var. **poetàrum,** Hort. (*N. poetàrum,* Haw.), blooms after var. *ornatus:* fls. large; segms. imbricated and slightly recurved; corona red or reddish to base.

Horticultural forms of *N. poeticus* are: *plènus* (Fig. 2450), double, late-fld.; *recurvus,* lvs. much recurved, and segms. recurving; *patellàris,* fls. flat, crown large, segms. much imbricated; *stellàris,* has a much distended bladder-like spathe. For poeticus forms, see Pugsley, Journ. Bot., Aug., 1915.



2450. Narcissus poeticus var. plenus. (×⅓)

N. abscíssus, Schult.=N. Pseudo-Narcissus var. muticus.—*Ajax* is an old generic name for N. Pseudo-Narcissus; this species is now sometimes called the Ajax narcissus.—*N. Báckhousei,* Hort. (N. Pseudo-Narcissus × incomparabilis; or N. Pseudo-Narcissus × Tazetta, or N. bicolor × poeticus) has single horizontal sulfur-yellow fls. with tube about half equaling the segms., the latter about 1–1¼ in. long; crown lemon-yellow, nearly equaling segms., erect, deeply lobed and plicate.—*N. Bárrii,* Hort. (N. poeticus × Pseudo-Narcissus or N. incomparabilis × poeticus), of the medium-crowned section, has yellow horizontal fls. with long, slender neck; "covers a series of forms intermediate between incomparabilis and poeticus, nearer the former than the latter" (Baker); Fig. 2446. G.M. 51:644. Gn. 73, p. 599; 78, p. 458 (all as N. Barrii conspicuus). A popular form (see p. 2106).—*N. Bernárdii,* Hen., is like N. Macleaii, but with a more plicate and deeper-colored corona, which is orange or lemon-yellow, and half as long as the spreading white segms. Pyrenees, said to occur where N. Pseudo-Narcissus var. muticus and N. poeticus grow together.—*Bunch-flowered daffodils* are N. Tazetta.—*N. Broussonètii,* Lag. Lvs. linear, about 4 to a st.: scape 1 ft., 2-edged: fls. many in an umbel, the cylindrical tube whitish, the oblong obtuse segms. ½in. long and pure white; crown rudimentary; anthers exserted. Morocco.—*N. Búrbidgei,* Hort. (probably N. incomparabilis × poeticus, in a series of forms). Short-crowned: it has the habit of N. poeticus, with a solitary drooping fl. with white horizontal or somewhat reflexed segms. and a very short corona with a yellow base and red rim.—*Cambricus* is an early bicolor form of N. Pseudo-Narcissus: segms. sulfur-white; crown or trumpet yellow.—*Capax plenus* is an old double form, lemon-yellow.—*N. CookSoniæ,* Hort., is a creamy-white variety of the Leedsii type. G.C. III. 47:336.—*Corbularia* narcissi are the N. Bulbocodium forms. Corbularia is an old generic name for this species.—*Daffodil.* The word daffodil is variously used. In this country it means usually the full double forms of N. Pseudo-Narcissus, plants that are very common in old gardens. Modern named varieties of this daffodil type are Van Sion and Rip Van Winkle. In England, however, daffodil is a more general term, used for most species except the Poet's narcissus (N. poeticus).—*N. élegans,* Spach (N. autumnalis, Link). Autumn-flowering: bulb globose, ½in. diam.: lvs. 1–4, appearing with the fls., very narrow, subterete: scape stiff and erect: fls. 2–6, on erect pedicels; perianth-tube cylindrical, whitish, about ½in. long; segms. spreading, lanceolate, pure white; crown very short, saucer-like, yellow. Italy, Algeria.—*N. Ënglehéartii,* Hort. Hybrids of N. incomparabilis and N. poeticus, the name of recent origin: much like N. Burbidgei but the flat crown or cup is ruffled or fluted. This comprises the relatively new section of "flat-eyes" or "flat-crowns," although the cup may take the form of a shallow wide-mouthed funnel.—*N. Fósteri,* Lynch. Garden hybrid between N. Bulbocodium var. citrinus and N. triandrus, the latter probably the male parent: scapes 2-fld.: fls. have the Bulbocodium character in size and shape of perianth, lanceolate segms. and declinate stamens: lvs. much like those of N. triandrus; crown and segms. pale yellow, tube greenish. G.C. III. 47:342.—*Flat-leaved* narcissi are the various forms of N. Pseudo-Narcissus.—*Ganymedes* is an old generic name for N. triandrus and its forms.—*Giganteus*=Sir Watkin.—*Grandiflorus* is applied to a large-fld. white form of N. Tazetta.—*N. Hùmei,* Hort., has a single nodding medium-crowned yellow fl. with long, straight cup about 1 in. long (often equaling the segms., but variable in size); segms. oblong, somewhat ascending, 1½ in. long: fls. said to have "a deformed clipt-off appearance." Ascribed to N. Pseudo-Narcissus and N. poculiformis.—*Incognita,* one of the Engleheartii forms, or by some referred to N. Barrii. Gn. 71, p. vii, Nov. 30 (1907); 73, p. 301. G.M. 54:300.—*N. Leèdsii,* Hort., has horizontal or drooping fls. with white segms. and yellow to whitish medium corona; described by Baker as having perianth-tube subcylindrical, ¾in. long; segms. spreading, oblong, acute, milk-white, to 1¼ in. long and to ¾in. broad; crown cup-shaped, ½in. long, sulfur-yellow, erect and irregularly crenate-plicate; style overtopping anthers and reaching nearly to throat of crown: intermediate between N. poculiformis and incomparabilis, but said by some to be produced by crossing white N. Pseudo-Narcissus varieties with N. poeticus. (See p. 2106.)—*Lent Lily*=N. Pseudo-Narcissus.—*Lobularius* is a confused name, usually applied to the deep yellow double daffodil, N. Pseudo-Narcissus.—*Lusitanicus* is a name for a bicolor N. Pseudo-Narcissus.—*N. Maclèaii,* Lindl., is a 1-fld. plant of small growth, bearing horizontal short-tubed fls. with milk-white segms. and medium-sized yellow crenate corona half or more the length of the lobes; segms. much imbricated, about ¾in. long, crown about ½in. long, minutely crenulate; style included. Of doubtful origin, several species having been suggested as parents. B.M. 2588. B.R. 987. Gn. 69, p. 103.—*N. Mastersiànus* is a hybrid of N. Tazetta and N. poculiformis.—*N. Mílneri,* hybrid of N. incomparabilis and N. Pseudo-Narcissus var. moschatus.—*N. minicýcla,* Hort. A garden hybrid between N. cyclamineus and N. minimus.—*N. montànus,* Ker=N. poculiformis.—*N. Nélsonii,* Hort., a subtype of N. Macleaii, very robust, and fls. larger (2–3 in. across), the lemon-yellow corona more than half as long as the segms.—*N. pallidus,* a whitish form of N. Pseudo-Narcissus.—*Pallidus præcox* is a pale sulfur-colored early form. Gn. 60, p. 320; 65, p. 271. G. 30: 215.—*Peerless* narcissi are the forms of N. incomparabilis.—*N. poculifórmis,* Salisb. (N. montanus, Ker; B.R. 123) has 1 or 2 nodding medium-crowned white fls. and a cup-shaped corona about half the length of the segms.; origin doubtful: by some regarded as a hybrid and by others as a native of the Pyrenees.—*Princeps,* sulfur-yellow and yellow-crowned, a form of the N. Pseudo-Narcissus type. G.C. III. 29:182.—*Queltia* is an old generic name to distinguish the group comprising N. incomparabilis.—*Rip Van Winkle* is a double variety of N. Pseudo-Narcissus.—*Roman* narcissus is a name for double-fld. N. Tazetta, white with orange cup. —*Rugilobus,* large-fld. variety of N. Pseudo-Narcissus, with primrose perianth and yellow trumpet. G. 16:89.—*Salmonetta,* raised by Engleheart: perianth clear white; cup salmon-orange; fl. star-like. Gn. 63, p. 393.—*Scoticus,* N. Pseudo-Narcissus with deep yellow corona and whitish segms.; known as Scotch garland lily. There is also a double form.—*N. serótinus,* Linn. Autumnal: bulb globose, 1 in. or less in diam.: lvs. appearing after the fls., very slender: scape very slender and jointed low down: fls. 1 or 2; tube subcylindrical, greenish; segms. oblanceolate, obtuse, spreading, pure white, about ½in. long; crown very short, 6-lobed, lemon-yellow. Medit. region.—*Sir Watkin* or *giganteus* is a very large-fld. form of N. incomparabilis.—*N. Spréngeri vomerénsis* is a garden hybrid between N. Pseudo-Narcissus and N. Tazetta. Carl Sprénger, Naples.—*Spurius,* a yellow N. Pseudo-Narcissus, a subform of var. major.—*Stella,* one of the star-narcissi of the N. incomparabilis group; now represented by Stella Superba, about twice the size, with long white spreading segms. and cup clear yellow. J.H. III. 43:269.—*Telamonius plenus* is the common sulfur-yellow double daffodil, N. Pseudo-Narcissus. Gn. 73, p. 227.—*Tortuosus* has twisted segms.: a form of N. Pseudo-Narcissus.—*Tridymus* is like N. Nelsoni, but has 2–3 smaller fls., with tube usually obconic (N. Pseudo-Narcissus × Tazetta).—*Van Sion* is a large pure yellow and very double form of N. Pseudo-Narcissus of the Telamonius set; much used for forcing. There is also a single Van Sion. —*Variiformis* is a form of N. Pseudo-Narcissus with canary-yellow corona and white segms., the fls. variable.—*N. viridiflòrus,* Schousb. Autumnal: bulb globose, 1 in. diam.: lvs. 1 or 2 to st., subterete, not appearing with the bloom: fls. 2–4, on a slender fragile scape, green in all parts; perianth-tube cylindrical and slender, about ½in. long; segms. lanceolate, reflexing, short; crown very short, 6-lobed; anthers barely exserted. Gibralter, Morocco; very late. B.M. 1687. G.C. III. 40:375.

L. H. B.

NARTHÈCIUM (the name may be derived from *Narthex,* the Greek name of Ferula, the stems of which were used as rods; or by others explained as an anagram of Anthericum). *Liliàceæ.* BOG-ASPHODEL. Perennial rhizomatous herbs.

Flowers yellowish green, the solitary pedicels subtended by a narrow bract, and bearing a small linear bractlet; perianth-segms. linear-lanceolate, obscurely 3-nerved, reflexed or spreading in fl., soon erect, persistent; stamens 6, included; filaments subulate, woolly; anthers linear-oblong; style none; the slightly lobed stigma sessile upon the attenuated apex of the ovary: caps. narrowly oblong, membranous, prolonged upward, splitting into 3 valves; seeds long with a straight tail at each end: lvs. 3–8 in. long, often less than ⅙in. broad; grass-like and vertical: sts. 1–2 ft. tall.—About 6 species, natives of northern hemisphere, Eu., E. Asia, Atlantic states, Calif.

The genus is close to Tofieldia in having a persistent perianth, simple racemes, and grass-like lvs.; resembles Simethis in the bearded filaments and simple style. The perianth is firmer than in most liliaceous plants and shows an approach to Juncaceæ, with which many botanists associate it. Some botanists call this genus Abama and assign it to the family Melanthaceæ.

califórnicum, Baker. Lvs. iris-like; basal ones ⅛–⅙in. broad; cauline lvs. 2–3 in number, short: raceme 3–5 in. long, loose: sts. 18–20 in. high: fls. 30–40, yellowish green: caps. of paper-like texture, slender at top, 3-valved, when ripe a bright salmon-color; seeds, including the points or tails, ½in. long. Swamps, Calif.—Intro. by dealers in native plants in 1888 or 1889.

M. B. Coulston.

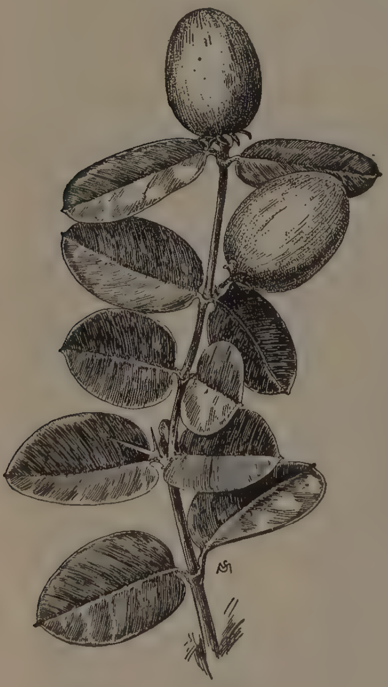
NASEBERRY: *Sapodilla.*

NASTÚRTIUM (classical Latin name of some cress, referring to its pungent smell: *nasus*, nose, and *tortus*, distortion). *Cruciferæ.* The name Nasturtium is used for two very different groups of plants. As a flower-garden name, it is used for plants of the Tropæolaceæ (see *Tropæolum*). It has also been used for certain crucifers, including the water-cress and horse-radish; but as a generic name it is now replaced, mostly by *Radicula*, which see.

NATAL PLUM, a handsome shrub (*Carissa grandiflora*, of the family *Apocynaceæ*), originally from South Africa, is cultivated in southern Florida and southern California for ornament and for its scarlet edible fruits the size of a plum. Fig. 2451. It is considered one of the best hedge plants in South Africa, and is sometimes used for this purpose in the United States. See *Carissa.*



2451. Natal plum.—Carissa grandiflora. (×½)

The Natal plum is a large shrub, eventually attaining to 15 or 18 ft., much branched and spreading, and armed with stout bifurcate spines: foliage dense, glossy green in color; lvs. opposite, ovate-acute, mucronate, thick and leathery, 1–2 in. long: fls. star-shaped, fragrant, about 2 in. across and borne in small terminal cymes; calyx composed of 5 oblong-acute lobes about ⅛in. long; corolla salverform, with a slender tube about ¾in. long and 5 oblong-obovate lobes twice the length of the tube and twisted to the left in bud; stamens 5, inserted upon the tube; style clavate; ovary superior, 2-celled, with several ovules in each cell.

The plant blooms most abundantly in early spring, but produces a few scattering flowers throughout the year; their waxy texture and fragrance are suggestive of the jasmine. The fruits, most of which ripen in summer, are ovoid or elliptic in form, commonly 1 to 2 inches long, with a thin skin inclosing the firm granular reddish pulp toward the center of which are several thin papery almost circular seeds,—sometimes as many as twenty or more. The fruit is very attractive in appearance, but is not generally relished when eaten out of hand; its flavor suggests the raspberry or cranberry, and when stewed it yields a sauce which greatly resembles that made from the latter fruit. It is also used for jelly and preserves. It is not of commercial importance in the United States, but is frequently planted in gardens for ornament and fruit. It seems well adapted to cultivation in both Florida and California, withstanding several degrees of frost without injury, and being somewhat drought-resistant. Among seedlings, however, there is great variation in productiveness, so that vegetative means of propagation must be used to perpetuate good varieties. Firminger states that grafting on *Carissa Carandas* renders the species more productive.

When used as a hedge-plant it withstands shearing admirably, but yields little fruit under these conditions. Its growth is compact and low, and it has the interesting habit of branching dichotomously. It succeeds on a variety of soils, from the lightest sand to heavy clay or adobe, and when left to itself will form a shapely attractive bush.

Seeds are easily germinated by planting in pans of light sandy loam. They should be as fresh as possible and barely covered with soil. Cuttings, when planted directly after removal from the parent bush, do not root very readily, but a method has been discovered by Simmonds whereby nearly every one will grow: this consists in notching young branchlets while still attached to the plant, making a cut half way through the stem 3 or 4 inches from the tip; the branchlet is then bent downward and allowed to hang limply until the end of the second month, when a callus will have formed on the cut portion, and the cutting may be removed and placed in sand under a lath shade, requiring another month to strike roots. The plant is also easily propagated by layering, and it is not difficult to bud, using the common method of shield-budding, essentially the same as practised with the avocado. Late spring is the best time to do the work.

Another species of Carissa in cultivation and which is sometimes confused with *C. grandiflora* is *C. bispinosa* (*C. arduina*). This can be distinguished from *C. grandiflora* by the much smaller size of the flowers, which are only ½inch broad, with the corolla-segments much shorter than the tube, and by the oblong-obtuse fruit which is only ½inch in length and contains one or two instead of many seeds lanceolate in outline.

Carissa Carandas, a species common in India, where it is known as karaunda, has also been introduced to this country. It is distinguished from the above two by the corolla-lobes being contorted to the right instead of to the left (as stated on page 664), by the oblong or elliptic-oblong leaves with rounded or obtuse tips, and by the spines being simple in place of bifurcate. Its fruits are ½ to 1 inch long, containing three or four seeds, and are much used in India for pickles and preserves.

F. W. Popenoe.

NATHÙSIA (Gottlob Nathusius, 1760–1838, Prussian plantsman). *Oleàceæ.* Four trees of India and tropical Africa seldom cult., for which see *Schrebera.*

NATIVE PLANTS. The desire for native and natural plants is one of the dominant notes of the present time. It is not strange that wild plants are not appreciated in a new country. The first necessity of civilization is to fell the trees that ground may be tilled and habitations be built. The necessities of life are imported; the literature is exotic; the plants are transported from other lands. In Europe the conditions of living had become established. People had outgrown the desire to remove. They appreciated their own plants and also those from the New World. American plants attracted attention in Europe rather than in America.

Twenty-five years ago, the writer made a census of indigenous American plants known to have been introduced to cultivation. The statistics were published in "Annals of Horticulture for 1891." It was found "that there are in North America, north of Mexico, about 10,150 known species of native plants, distributed in 1,555 genera and 168 families. Of these, 2,416 species are recorded in this census, representing 769 genera and 133 families. Of this number, 1,929 species are now offered for sale in America; 1,500 have been introduced into England, of which 487 are not in cultivation in this country." All these species are there catalogued. The only other account of the entire cultivated flora is that which was compiled in the "Cyclopedia of American Horticulture," 1900–1902, and for which the lists of twenty-five years ago were a preparation. That Cyclopedia described 2,419 species of plants native to North America north of Mexico. A brief sketch of the history of recent efforts toward the introduction of native plants is given in the preface to the catalogue of 1891.

Formerly, the term "American plants" had a technical meaning in England. William Paul in his book on "American Plants," published in London in 1858, writes as follows: "The history of American plants may be briefly told. The term is popularly applied to several genera, principally belonging to the natural order Ericaceæ. They are generally 'evergreen,' producing their flowers for the most part in the months of May and June." The book is devoted largely to rhododendrons, azaleas and kalmias, although European and other heaths are included.

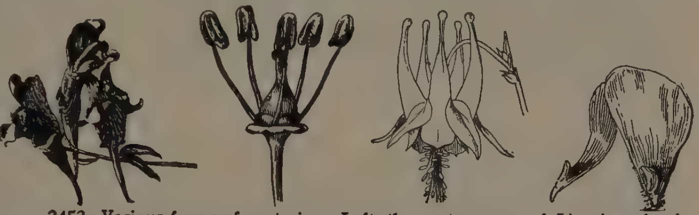
There is a strong tendency toward the production of peculiarly American types and races even in species domesticated from other countries, as of the carnation and sweet pea. As American plant-breeders give greater attention to native species, the divergencies between the horticulture of the Old World and that of the New World will be accentuated. The recent multiplication of books about native plants has stimulated interest in the indigenous resources. L. H. B.

NAUMBÙRGIA: *Lysimachia.*

NAUTILÓCALYX (apparently *nautilus-shaped calyx*). *Gesneriàceæ.* Herbs of Trop. S. Amer., usually referred to Episcea, but lately separated and re-defined by Sprague (Kew Bull. 1912, 85). As now constituted, it comprises species named in Episcea and Alloplectus, 9 being included altogether. Two of these may be mentioned here, although apparently not in the American trade. The species of Nautilocalyx have the general habit and appearance of Episcea, but differ in having ovules on the inner surface only of the placental plates rather than on both surfaces. They are distinguished from Alloplectus in being herbs rather than shrubs and undershrubs, and in bearing a larger corolla-limb.

N. Fórgetii, Sprague (*Alloplèctus Fórgetii*, Sprague). Fls. pale yellow, corolla hairy outside, the calyx-segms. much shorter than the corolla-tube: lvs. with very wavy margins, somewhat truncate at base, green above and red along the ribs and veins beneath: petioles 2 in. or less long, villous. Peru. *N. pállidus*, Sprague (*Alloplèctus pállidus*, Sprague). Fls. creamy white, the corolla hairy outside and the front part of the tube purple-striped inside and the back part with broad band of purple blotches: lvs. gradually narrowed to base, nearly glabrous above, minutely puberulous beneath. Peru. B.M. 8519. L. H. B.

NECTAR. Most flowers pollinated by insects possess nectar-glands, simple or composite, located upon some part of the floral structures. To designate nectar by its chief constituent would be simply to call it a sugar solution, more or less watery or dense, depending upon the flower, or upon the conditions under which produced. However, several sugars may be present, as well as small quantities of other substances. Just as in honey, the predominant form is fruit-sugar, with cane-sugar next in importance, and always with small amounts of aromatic substances yielding the odor and affecting the taste of the product. Sometimes mucilaginous substances are present. Honey contains less water than nectar, also other aromatic compounds and small amounts of waxes and pollen. The abundant secretion of nectar is, to a large extent, dependent upon external conditions, and usually is favored by conditions inducing the perfection of the flowers.



2452. Various forms of nectaries. Left, the nectar-spurs of Linaria vulgaris; the cushion-like nectaries in a grape flower; nectaries of columbine; right, the nectar-scales on petals of ranunculus.

Nectaries occur on various parts of the flowers, often about the base of one or more petals, or even stamens; again, they may take the form of glandular protuberances or ridges arranged between any of the whorls of floral members; while the most interesting and conspicuous modifications involving the nectaries are those in which one or more of the petals or other floral leaves may be changed into pockets, spurs, or receptacles. Some of the interesting types of modification may be noticed in the violet, columbine, nasturtium, and certain orchids. An extreme form is found in a Madagascar orchid, angræcum, in which the nectar-tube may be 6 inches long. Various nectaries are shown in Fig. 2452. In all cases, the nectar is secreted from glandular cells located either superficially or more deeply in the tissues, and in the latter case connected with the receptacle by nectar-ducts. The secreting cells may be confined to a single small spot or may be spread over a larger area or zone.

The development of the curious and complicated nectaries referred to indicates a remarkable adjustment for insect pollination, and whatever may be the immediate explanation of the development of these structures, they serve a most useful purpose in effecting cross-pollination. It is necessary to add, however, that the secretion of sugary liquids by plants is not confined to nectaries, and oftentimes the relation of these secretions to any useful purpose is not clear. The production of "honey-dew" by certain plants, normally or through the incitation of aphid punctures, is allied to nectar-secretion. The opportunities determining the excretion of sugars by nectaries have been considerably studied by physiologists; but, for these facts, the reader must seek information in papers dealing more extensively with the osmotic properties of cells, as the subject is too technical for discussion here. B. M. DUGGAR.

NECTARINE, a smooth-skinned peach (*Prunus Persica* var. *nucipersica*). Fig. 2453. It was formerly thought to be a distinct species of plant. By DeCandolle it was called *Persica lævis.* Roemer in 1847 made

2453. Nectarines.

two species of it, *Persica violacea*, the freestone nectarines, and *P. lævis*, the clingstone nectarines. It is now known, however, that nectarines often come from seeds of peaches, and peaches have come from seeds of nectarines; and yet it is not impossible that a distinct species is involved in the nectarine group. Either may originate from the other by means of bud-variation. (See Darwin's "Animals and Plants under Domestication" for historical data.)

The cultivation of the nectarine is in all ways like that of the peach. Because of the smooth skin of the fruit, it is perhaps more liable to the attacks of curculio. It is less popular in the market than the peach, and therefore is less grown, although in California it is planted on a commercial scale. In that state it does well on almond stocks. Nectarines are usually inferior to peaches in quality, probably because less attention has been given to the breeding and selection of varieties, and from the fact that there is no conventional standard of excellence. Nectarines thrive in the peach regions. Varieties are few, as compared with peaches. The most prominent in this country are Boston, Downton, Hardwick, Early Newington, Pitmaston Orange, Stanwick, Humboldt, Lord Napier, Advance, Elruge. In color, size and season, nectarines vary as do peaches. See also *Peach*, and *Prunus*.

L. H. B.

The nectarine is grown in California almost exclusively for drying and cannning, and even for these uses is but of minor importance. As compared with peaches for canning, the product of nectarines is only about one-eighth of 1 per cent that of the peach, and for drying only about 1 per cent that of the peach. The varieties grown for both canning and drying are the white varieties, because they do not color the syrup in canning and because when sulfured they make a beautiful amber-colored translucent product. E. J. Wickson.

NEGÚNDO: *Acer*, page 204.

NEÌLLIA (named after Patrick Neill, at the beginning of the nineteenth century secretary of the Caledonian Horticultural Society at Edinburgh). *Rosàceæ.* Ornamental shrubs chiefly grown for their graceful habit, the handsome bright green foliage and the attractive flowers.

Deciduous: lvs. stipulate, alternate, short-petioled, doubly serrate and usually more or less lobed: fls. in racemes; calyx-tube rather large, campanulate or almost tubular, with 5 short erect sepals exceeding the 5 oval petals; stamens 10–30, carpels 1 or 2 with terminal slender styles: pod dehiscent only at the inner suture, with several shining seeds. From Spiræa it differs, like the allied genera Physocarpus and Stephanandra, by its stipulate lvs. and shining crustaceous seeds.—About 10 species in China and the Himalayas.

The neillias are graceful shrubs, with spreading branches, bright green generally ovate leaves and with pink or whitish rather small flowers in terminal racemes. *N. sinensis*, which is the handsomest of the species in cultivation, and *N. longeracemosa* have proved fairly hardy at the Arnold Arboretum, while *N. thyrsiflora* requires protection even in the Middle States, and is often killed to the ground in severe winters, but usually vigorous young shoots spring up and bloom and fruit in the same season. On account of their graceful habit and handsome foliage they may be used as border plants for shrubberies. They grow in any good moderately moist soil. Propagation is readily effected by greenwood cuttings under glass and also by seeds treated like those of spirea.

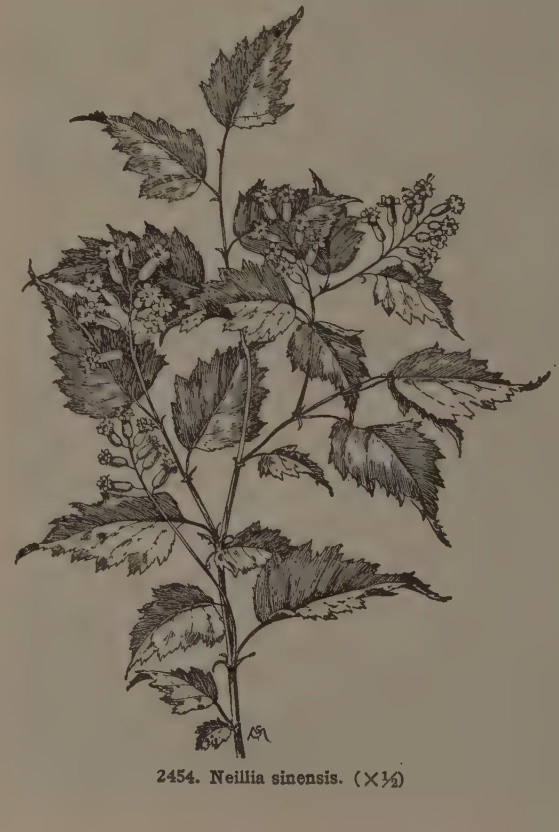
A. *Fls. whitish; racemes collected into terminal panicles.*

thyrsiflòra, D. Don. Upright shrub, to 6 ft. high, but usually not exceeding 2 ft. if annually killed to the ground: branches angular, glabrous: stipules rather large, serrate: lvs. ovate to ovate-oblong, cordate at base, long-acuminate, usually 3-lobed, incised-serrate, glabrous above, pubescent on the veins or glabrous beneath, 2–4 in. long: fls. short-pedicelled, in terminal and axillary racemes 1½–3 in. long and crowded into terminal panicles, rarely solitary; calyx-tube campanulate, pubescent, with the sepals about ⅓in. long. Aug., Sept. Himalayas. R.H. 1888, p. 416.

AA. *Fls. pink; racemes solitary.*

longeracemòsa, Hemsl. Shrub, to 10 ft.: branchlets terete, pubescent: lvs. ovate to ovate-oblong, acuminate, rounded or subcordate at the base, incised-serrate, rarely 3-lobed, glabrous above, pubescent on the veins and veinlets beneath, 1½–2½ in. long; stipules lanceolate, entire: fls. pink, about ⅓in. long, short-pedicelled, in dense racemes 1½–3½ in. long or sometimes longer; calyx tubular-campanulate; ovary hairy only at the apex. June, July. W. China.

sinénsis, Oliver. Fig. 2454. Shrub, to 6 ft.: branchlets terete, glabrous: lvs. ovate to ovate-oblong, acuminate, rounded at the base, incised-serrate, usually lobed,



2454. Neillia sinensis. (×½)

sparingly hairy or nearly glabrous, 1½–2½ in. long; stipules lanceolate, entire, usually conspicuous: fls. about ½in. long, slender-pedicelled, in terminal racemes 1–2½ in. long; calyx tubular, glabrous or with glandular bristles; ovaries hairy at the apex. May, June. Cent. China. H.I. 16:1540.

N. affìnis, Hemsl. Closely allied to N. longeracemosa. Branchlets glabrous: lvs. broader, nearly glabrous: racemes shorter; calyx sometimes bristly; ovary villous. W. China.—*N. amurênsis*, Nichols.=Physocarpus amurensis.—*N. opulifòlius*, Brew. & Wats. =Physocarpus opulifolius.—*N. Tanákæ*, Franch. & Sav.=Stephanandra Tanakæ.—*N. thibética*, Franch. Closely allied to N. longeracemosa. Lvs. cordate, pubescent beneath, slightly 3-lobed; stipules ovate, often sparingly toothed: calyx-tube cylindric, pubescent and often bristly; ovary silky pubescent. W. China.—*N. Tórreyi*, Wats.=Physocarpus monogynus.

Alfred Rehder.

NELÚMBO (Ceylonese name). Usually written *Nelumbium. Nymphæàceæ.* Nelumbium. Two strong-growing aquatics, one yellow-flowered and native to North America, the other white or cyanic-flowered and native of the Orient.

From Nymphæa, or the true water-lilies, Nelumbo differs technically in having distinct carpels, which are imbedded in the receptacle, with a single ovule in each. Nelumbiums have strong and thick and usually tuber-bearing rhizomes, which creep in the earth in the bottoms of ponds and slow streams: lvs. peltate, orbicular or nearly so, entire, usually very large and long-petioled and mostly standing high above the water (floating when from young plants or in deep water): fls. large and showy, single, on peduncles which equal or exceed the lvs.; sepals 4 or 5; petals many, erect or erect-spreading; stamens many, on broad, short filaments: fr. a large, flat-topped perforated receptacle (Fig. 2455), in which are immersed the many carpels. The bold and characteristic form of the nelumbiums lends itself well to conventional designs, as in Fig. 2456.

Nelumbiums are bold plants, suitable for large ponds and for masses. They may be grown in tubs, or better in the open pond, as the rhizomes may run 30 or 40 feet in a year. *N. lutea* flowers well only when thoroughly established and in entire freedom; it is sometimes crowded out by *N. nucifera.* The latter species, commonly but incorrectly known as Egyptian lotus, is one of the best of large pond plants, being grown for its stately habit and showy flowers. Its roots should not freeze. Covering the pond with boards and litter, or filling it with water, may be made to afford ample protection.

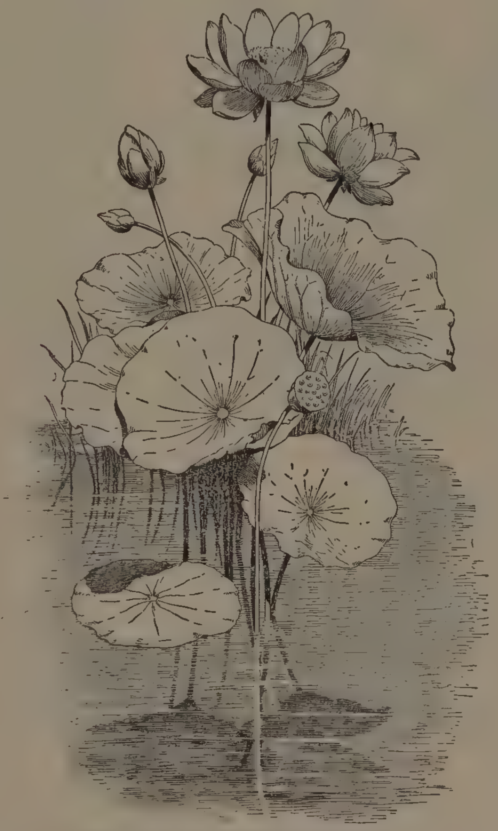
A. *Fls. yellow.*

lùtea, Pers American Lotus, or Nelumbo. Water Chinkapin. Lvs. usually raised 2–6 ft. out of shallow water, cupped or depressed in the center over the attachment of the petiole, 1–2 ft. across: fls. pale sulfur-yellow, 4–10 in. across, with obovate-obtuse concave petals and hook-appendaged anthers. S. Ont. to Minn., Neb., Fla. and La.; usually local. G.F. 9:375. Mn. 10:113. V. 19:9.—A bold and useful plant for colonizing, deserving to be better known. *N. flavéscens*, Hort., produces more but smaller fls. and has a red spot at center of lf.; possibly a hybrid.

AA. *Fls. pink, red or white.*

nucífera, Gaertn. (*Nelúmbium speciòsum*, Willd. *Nelúmbo índica*, Pers., and *N. Nelúmbo*, Karst.). East Indian Lotus. Fig. 2455. Lvs. usually larger than those of *N. lutea*, glaucous: fls. fragrant, usually pink except in horticultural varieties, overtopping the lvs. Caspian Sea to Japan, Philippine Isls., India and N. Austral.; naturalized at Bordentown, N. J., where it was intro. by E. D. Sturtevant. A.G. 15:334. C.L.A. 4:275; 5:301. G. 7:16; 28:395. Gn. 28, pp. 426, 429; 43:463; 44, pp. 229, 435; 50, pp. 267, 469; 57, p. 397; 66:171; 76, p. 447. Gng. 5:114; 6:295; 15:334. G.C. III. 52:119. G.M. 38:809; 40:34; 41:833–5. G.W. 2:377. I.H. 42:27. R.H. 1900, p. 243. V. 15:97.—This plant is known to the trade as Egyptian lotus, but the lotus of the ancient Egyptians is a Nymphæa. This plant is not native to the Nile region. Many named forms are cult., e.g.: Fls. white: Var. **álba** (*N. álba*, Hort.), the "magnolia lotus." Gn. 28, p. 427. G.C. III. 14:41. Var. **álba grandiflòra**, larger-fld. A.F. 14:726. A.G. 20:369. Gng. 7:146. Mn. 9:73. Var. **álba striàta**, edge of petals striped and tipped with red. Var. **pygmæ̀a álba**, dwarf: lvs. 6 in.: fls. 4 in. across. Var. **álba plèna** (*N. Shiròman*), large, double Japanese form. A.F. 16:229. F.E. 10: suppl. Feb. 12. Gn. 60, p. 158. Gng. 9:3. Var. **pygmæ̀a álba plèna**, dwarf, double. Fls. pink to red: Var. **Kinshìren**, white shaded pink. Var. **kermesìna**, light rose. Var. Grossherzog Ernst Ludwig (=*N. flavescens* × *N. Osiris*), salmon-rose. Var. **pygmæ̀a ròsea**, dwarf, bright rose. Var. **ròsea**, Hort., deep rosy pink. Var. **Osìris**, deep rose. Gn. 72, p. 457. Var. **púlchra**, dark rosy red. Var. **pekinénsis rùbra**, rosy carmine. Var. **gigantèa**, very large, rose-purple. Var. **ròsea plèna**, double, deep rosy pink. G.W. 5:411. Var. **pekinénsis rùbra plèna**, very large, double, rosy carmine.

H. S. Conard.



2455. The Indian lotus, Nelumbium speciosum, of the trade, but properly Nelumbo nucifera.

Nelumbium in cultivation.

Whilst it may be historically true that the Egyptian lotus is not a Nelumbium, the *Nelumbium speciosum* (or more properly *Nelumbo nucifera*) is everywhere known under that name, and it has been so distributed in good faith. In fact, it is doubtful whether it is worth while to change the common name at this time.

America may be honestly proud of possessing such a fine aquatic plant as *Nelumbo lutea*, the well-known American lotus. While China and Japan are the recognized homes of the splendid *Nelumbo nucifera*, they do not possess a yellow lotus. In the central states and near the Great Lakes, *N. lutea* is found in abundance, but it is scarce in the Middle Atlantic and eastern states. When well established it is a magnificent plant, and when in blossom it is a sight worth traveling miles to see.

Nelumbiums, with nympheas and other aquatic plants, were among the few flowers known or cultivated by the ancients. No mention is made in history of a yellow lotus prior to the discovery of America by white men, but over four centuries ago it was well known to the Indians and cultivated by them in the waters of the Tennessee and Cumberland rivers, and was abundant on the tributaries of the Mississippi. It was carried northward and eastward by the Indians, and was established as far east as Connecticut. At the present time (1914), it is established and cultivated in most of the states of the Union.

2456. Metal fountain in Nelumbo form.

The late Isaac Buchanan received tubers of *N. nucifera* from Japan, which were planted in a stream on Long Island, but there they perished. Later, other efforts were made, and some tubers from the same source were received and planted by Samuel Henshaw in an artificial pond in the gardens of the late Mr. Green, at New Brighton, Staten Island, New York, where they grew most satisfactorily, some of the original stock being still in evidence on the estate.

About the same time E. D. Sturtevant, of Bordentown, New Jersey, who had introduced a number of tender water-lilies into commerce, and knowing of its being grown in the Jardin des Plantes, Paris, made an examination of the condition under which it existed there and determined to experiment in the culture at Bordentown, New Jersey. Roots were obtained from Kew Gardens and afterward planted in shallow water in a sheltered spot in a millpond near Bordentown. Here the plant grew amazingly, and its success and hardiness were fully established. From here was disseminated the now famous Egyptian lotus, *Nelumbo nucifera,* to all parts of the United States. Several varieties have since then been introduced from Japan, including white and delicately tinted varieties, also deep rose, and double forms of both white and rose.

The cultivation of the nelumbium is of the simplest. The roots or tubers should not be transplanted until there is evidence of growth, as the tubers, being usually buried deep in the soil below the water and out of the reach of frost, are not affected by the warm rays of sunshine as early as nympheas and other terrestrial plants. If nelumbiums are dug before they start into growth, the tubers should be kept in a warm place or planted where the temperature is such that growth will begin at once. In the Middle Atlantic States and eastward and westward, May is the best time to transplant; southward earlier. Tubers may be planted in shallow water near the margin of the pond where it is intended they shall grow. The tuber should be placed horizontally in the soil, first making a little trench or opening to receive the same and covering with about 3 inches of soil. Means must be employed to keep the tuber securely in position and, if necessary, a stone or brick laid over the tuber. When the season is late or circumstances delay the planting season until June, it will be safer to secure plants in pots or tubs. These, beside being somewhat advanced, will transplant with a greater degree of certainty and more satisfactory results. In artificial ponds a walled section should be built to hold the soil and keep the roots within bounds. The walls should have no corners at right angles; where there are such they should be rounded off, so that the runners are not intercepted and crowded in bunches at the corners. The natural soil and deposits in ponds are, in most cases, all that is required for these plants. They will flourish equally well in a stiff or tenacious soil, but when grown in artificial ponds it is best to use a mixture of two parts turfy loam and one part thoroughly rotted cow-manure. Do not use fresh or green manure, and when possible have sods cut in the fall and stacked with the manure (in this case it may be fresh). In early spring, have the same turned over two or three times before using. Resort may be had to cultivation in tubs, but the lotus being such a gross feeder, the result in most cases is that the plants are starved into rest at an early date. The leaves turn a sickly yellow and present a sorry appearance, and in many cases produce no flowers. If no other method can be adopted, then secure the largest tubs possible and during the growing season use liquid or artificial manure liberally. An excellent method to grow nelumbiums under artificial conditions is to excavate a hole 5 to 6 feet in diameter and 2½ feet deep with slightly sloping sides. Have a form in readiness to place inside the excavation, leaving about 4 inches clear for concrete. The form can be of light material, the size of the pool desired, so braced as to hold the concrete in place until set. Place heavy chicken wire netting in the opening for reinforcement and secure in place when filling so as to be in the center of wall. When finished, this makes an ideal pool for nelumbiums or water-lilies, watertight and frostproof. Use two bags Portland cement, three wheelbarrows of sand and five wheelbarrows gravel or finely broken stone.

It must be understood that while the nelumbiums are hardy, they are so only as long as the tubers are out of the reach of frost. The depth to which frost penetrates the soil or water may be termed a dead-line.

The tubers are farinaceous and edible, and are of considerable market value in Japan, but a taste must first be cultivated for them in the United States. The muskrat, however, has developed a highly cultivated taste for these sacred morsels, and it is necessary to watch these animals lest they take up their abode near ponds where the nelumbiums grow. There are now in cultivation in the United States a dozen or more varieties, including single and double forms, pure white to deep rose, and yellow.

As to insect pests, black-fly or black aphis is sometimes troublesome. The best remedy is the lady-bird beetle and its larvæ. Also spray with tobacco water. The leaf-cutter, or roller, is prevalent in some sections, and both young and old leaves are attacked, also the stems of the leaves and flowers. These have their natural enemies in the form of wasps and even sparrows, and as no liquid insecticide can be used, only such as are in the shape of a dry powder can be depended on. Paris green, mixed with land plaster or plaster and powdered slaked lime, is excellent, but dry hellebore in powder-form, or slugshot applied by a powder bellows is the best material to exterminate them. A borer in the leaf-stalks sometimes does great damage, killing nearly all the leaves, so that no blooms are made. Apply "slug-shot" with a bellows. Sometimes the diseased leaves are mowed off and destroyed, and a second growth may escape the borers.

Wm. Tricker.

NEMÁSTYLIS (Greek, *thread-like styles*, because the styles are not united). Syn., *Nemastylus. Iridàceæ.* Tender American bulbs, with blue six-lobed flowers about an inch across which last only a day.

Erect plants, with slender, usually branched sts.: root-lvs. linear: spathes 1 or more, peduncled: fls. rather large, more than 1 to a spathe; perianth of 6 segms. without a tube; inner segms. a little smaller than the outer; ovary 3-celled; filaments more or less united; anthers short; ovules many, superposed; style-branches alternate with the anthers: caps. loculicidally 3-valved, oblong, ovoid or obovoid.—Strictly, Nemastylis is a genus of 3 species, found only in the S. U. S. and characterized by having the filaments nearly free. Baker, however, in his Handbook of the Irideæ, includes Chlamydostylis as a subgenus of 17 species found from Mex. to S. Amer. and characterized by having the filaments united in a column to the summit. Some of the following species have been rarely advertised by dealers in native plants; the others by Dutch bulb-growers.

A. *Filaments nearly free.* (*Subgenus Nemastylis proper.*)

B. *Cluster of fls. single: spathes usually 1-fld.*

cœléstina, Nutt. Root-lvs. 1–2, 1 ft. or more long: st. 1½–2 ft. long, bearing 3–4 reduced lvs.: fls. sky-blue. Pine barrens, Fla. to Ga., and westward through Texas.—Differs from *N. acuta* in having more broadly ovate perianth-lobes.

BB. *Clusters of fls. 2–3: spathes 2–3-fld.*

acûta, Herb. (*N. geminiflòra,* Nutt.). NORTHERN NEMASTYLIS. Root-lvs. 2–3, ½–1 ft. long: st. ½ ft. long, bearing 1 large linear lf. at the fork, and sometimes another below it: fls. bright blue or purple: bulb dark colored, ovoid, scaly, 1 in. or less long: caps. obovoid. Texas, to Mo., La., and Kans., Ark. and Tenn. B.M. 6666. F.S. 21:2171.

AA. *Filaments united in a column to the summit.* (*Subgenus Chlamydostylis.*)

B. *Fls. brownish purple, inner segms. tipped yellow.*

brúnnea, Wats. St. 1 ft. long, bearing a single lf. 6–8 in. long and a sheathing bract at the base of the peduncle: spathe 2½ in. long, several-fld.: outer perianth-segms. obtuse, inner ones acuminate, brown-purple, the inner segms. tipped yellow; anthers yellow. Mex.

BB. *Fls. pale blue.*

Prínglei, Wats. St. usually simple, with a single lf. at the middle: radical lvs. shorter than st., 2–3-nerved: spathe 1½ in. long: fls. fragrant; outer segms. obtuse, inner ones minutely apiculate, pale blue: caps. oblong. Mex., province of Chihuahua.

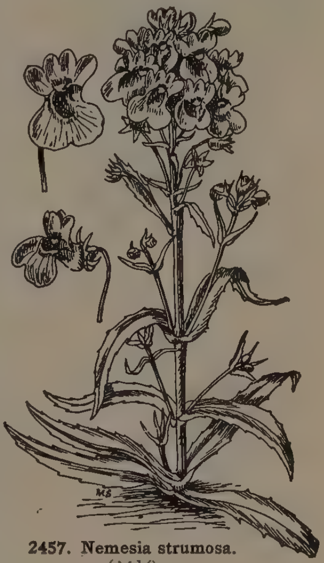
WILHELM MILLER.
A. C. HOTTES.†

NEMÈSIA (old name used by Dioscorides for some sort of snapdragon). *Scrophulariàceæ.* The genus includes attractive flower-garden half-hardy annuals.

Herbs annual or perennial, sometimes undershrubs, the annual kinds having come into cult: lvs. opposite: fls. very variable in color, from yellow to white and purple, in terminal racemes or axillary (racemose in the garden kinds), the pedicels bractless; calyx 5-parted; corolla with short tube which in front bears a spur or pouch; corolla-limb 2-lipped, the upper or posterior lip 4-notched or -cleft and the lower or anterior of one shallow-notched or entire lobe with palate at base; stamens 4, didynamous, the anthers 1-celled and usually cohering about the stigma; ovary 2-celled: caps. with boat-shaped valves.—Species about 50, of which a very few are Trop. African and the remainder S. African. Cf. Hiern, Flora Capensis, IV: II (1904). *N. strumosa* was one of the horticultural novelties in the last part of the 19th century. The fls. are very distinct in shape and have a wide range of color. They are about an inch across and borne in great profusion. If started indoors in March and transferred to the open in May the plants will furnish continuous bloom from June to Sept. The colors range from white, through pale yellow and rose, to orange and crimson, with numerous intermediate shades and a great variety of throat markings. This species has been known to botanists nearly a whole century; it grows only 50 miles from Cape Town, and it exhibits all these colors in the wild, yet it was never exploited until 1893, the first live plants seen in Eu. being shown in 1892. Sixteen distinct color varieties were recognized in the first batch of cult. plants, and the process of selecting strains has probably only begun. The nemesias are of easy cult. They may stand about 6 in. apart in the garden beds.

A. *Fls. with a sac or pouch at the base.*

strumòsa, Benth. Fig. 2457. Erect, branches, 4-angled, glabrous below and more or less pilose above, 6–24 in. high: root-lvs. oblong-spatulate, entire or dentate; st.-lvs. lanceolate or linear, dentate, sessile: racemes in wild plants, 2–4 in. long, terminal, becoming subcorymbose and afterward elongating; fls. white or in shades of yellow and purple, often purple-marked on the outside, the bearded throat spotted on a yellow ground; upper lip about ½in. long and often 1 in. broad; lower lip about 1 in. broad: caps. 4–6 lines long, 3–4 lines wide. S. Afr. B.M. 7272. G.C. III. 12: 277. R.H. 1898, p. 87 (var. *grandiflora*). V. 16:7. G. 31:315.—It varies into a number of forms, some of them compact. Var. **Súttonii,** Hort., is a series of improved forms, with large fls. of many colors, pale yellow, rose-pink, white, rich orange, crimson and scarlet being now offered separately. G.M. 35: 459; 43:311. Gn.W. 9:289; 18:637. J.H. III. 51:58.



2457. Nemesia strumosa. (×¼)

AA. *Fls. with a spur at the base.*

versícolor, E. Mey. Erect or ascending, nearly glabrous below and slightly pilose above, simple or branched, 1 ft. or more high: lowest lvs. somewhat stalked and ovate or narrower; upper lvs. few, sessile, oblong, lanceolate or linear, entire or toothed: racemes sub-corymbose and lengthening, 1–3 in. long in the wild; fls. "variable in color, either white and striate outside or cinnabar-red, striate outside and sulphur-coloured on the throat or sulphur-colored and not striate" (Hiern); lobes of the upper lip equal among themselves and as long as the lower lip; throat with 2 callosities, pubescent; spur incurved or nearly straight, about as long as the lower lip. S. Afr. Var. **compácta,** Hort. (*N. compácta,* Hort.). A compact and attractive free-flowering race, 8 in. to 1 ft., excellent for borders and rock-gardens, with fls. in white, rose, violet, and blue. Var. **compácta trícolor,** Hort., has white, rose, and violet in the fls. R.H. 1898, p. 87.

floribúnda, Lehm. Erect, 6–15 in., glabrous below and somewhat pilose above, the sts. 4-angled: lower lvs. stalked, oval or ovate, dentate; upper ones few, small, ovate or lanceolate, subsessile: racemes rather open, subcorymbose or oblong, 1–5 in. long in the wild; fls whitish; upper corolla-lobes oblong, very short; lower lip somewhat longer and 2-lobed; mouth closed; spur nearly straight and obtuse long-conical. S. Afr. B.R. 24:39.—Fls. smaller and with a narrower range of colors than in *N. strumosa.*

lilácina, N. E. Br. Much branched, minutely glandular-pubescent, to 15 in. high: lvs. narrow-lanceolate, to 1½ in. long, toothed: racemes to about 1 ft. long, loose, the pedicels slender; fls. small, lilac; upper lip scarcely ⅛in. long, purple-striped; lower lip about same length, yellow-marked on the palate; spur whitish, short. German S. W. Afr.

2458. Nemopanthus mucronata. (×¼)

NEMOPÁNTHUS (from the Greek, referring to the thread-like flower-stalks). Also spelled *Nemopanthes. Aquifoliàceæ.* Mountain Holly. Ornamental shrub planted for its attractive fruit and handsome foliage.

Deciduous: lvs. alternate and partly fascicled, slender-stalked, entire or slightly toothed: stipules small, caducous: fls. polygamo-diœcious, small, whitish, 1 or few on slender axillary pedicels; calyx in the staminate fls. of 4–5 deciduous teeth, ovate in the fertile fl.; petals distinct, 4–5, linear; stamens 4–5, free, with slender filaments: fr. a drupe with 4–5 bony nutlets.—One species in N. E. N. Amer. Closely allied to Ilex, which differs chiefly in the persistent calyx and in the stamens being adnate to the petals, which are slightly united at the base.

The mountain holly is a much-branched upright shrub with medium-sized generally oblong bright green leaves, inconspicuous whitish axillary flowers followed by attractive globose red fruits on slender drooping stalks. It is hardy North and prefers moist soil; it does well in partly shaded situations. Propagation is by seeds; also by greenwood cuttings under glass.

mucronàta, Trel. (*N. canadénsis,* DC. *N. fasciculàris,* Raf. *Ilicioìdes mucronàta,* Brit.). Fig. 2458. Shrub, to 10 ft.: young branches purplish, older ones ashy gray: lvs. elliptic-oblong, mucronate, entire or sometimes slightly toothed, paler beneath, glabrous, 1–1½ in. long: fls. solitary or few, small, on slender peduncles ½–1 in. long: fr. subglobose, ¼–⅓in. across, dull red. May, June; fr. in Aug., Sept. Canada to Wis., Ind., and Va. B.B. (ed. 2) 2:490. I.T. 3:81.

Alfred Rehder.

NEMÓPHILA (Greek, *nemos,* a grove, and *phileo,* to love; referring to the habitat of some species). *Hydrophyllàceæ.* Hardy annual herbs blooming abundantly from early spring to late summer.

Whole plant more or less hairy: st. diffuse, becoming prostrate: lvs. alternate or opposite, pinnately lobed or divided, petiolate: fl.-stalks usually longer than the lvs., terminal or lateral, slender, 1-fld., in one or two species inclined to be racemose; fls. blue, white, purple, or variously spotted; calyx 5-parted; lobes erect or spreading, with 5 supplementary reflexed lobes alternating with them, increasing in size when fruiting; corolla broadly bell-shaped or wheel-shaped, deeply 5-lobed, with 10 scaly appendages on the inside of the throat; ovary hairy; styles glabrous: caps. globose, hairy, smaller than calyx-lobes. The chief source of information is in the monograph of the Hydrophyllaceæ in Das Pflanzenreich, hft. 59, p. 42, by A. Brand; also in Syn. Flor. of N. Amer., vol. II, part I, p. 155, by Asa Gray. Brand recognizes 18 species and over 50 subspecies and varieties, all from N. Amer.

Nemophilas are of dwarf, compact habit, and produce an abundance of showy bell-shaped flowers from early spring to late summer; hence they are valued for bedding and for the border.

A. *Lvs. mostly alternate, all with an ear-shaped and clasping base or winged petiole.*

aurìta, Lindl. St. 1–3 ft. long, weak, with stiff, recurved bristles by which the plant tends to climb: lvs. mostly alternate, the lower opposite, deeply cut above into 5–9 oblong or lanceolate segms. which are usually turned back: later fls. not accompanied by lvs., and hence appearing to be in loose racemes; corolla about 1 in. broad, violet. Blooming from March till May, low, shady grounds. Calif. from Sacramento Valley to San Diego. B.R. 1601.

phacelioìdes, Nutt. Sparsely hairy, 1–2 ft. tall: lvs., all but earliest, alternate; lf.-segms. obtuse, margin slightly ciliate; lower lvs. narrowed into a short naked petiole; lobes notched at end: corolla bell-shaped, blue with white or pale center: seeds slightly pitted. Low ground. W. N. Amer., Ark., Texas. B.R. 740. B.M. 2373.

AA. *Lvs. opposite.*

B. *Fls. one color, or dotted or veined.*

Ménziesii, Hook. & Arn. (*N. atomària,* Fisch. & Mey. *N. modésta,* Kellogg. *N. pedunculàta,* Benth.). St. straggling, succulent, procumbent, pilose: lvs. pinnatifid, the lobes ovate, nearly entire, slightly hairy: fls. light blue to nearly white, marked with dark brown spots toward the center or sometimes with a dark eye. Low grounds, W. Amer., Calif. to Ore. B.R. 1940. B.M. 3774. P.M. 5:99. V. 2:267. Brand makes 19 subspecies and botanical varieties of this species, of which some are important horticulturally. Var. **discoidàlis,** Hort., in which the spots on the corolla are confluent into a large, brownish purple eye. Other garden forms are: var. **vittàta,** Hort., velvety black margined with white (Gn. 9, p. 232); var. **élegans,** Hort. (*N. atomària* var. *élegans,* Hort.), fls. pure white, with chocolate center.

2459. Nemophila Menziesii var. insignis. (×½)

(V. 2:268); var. **oculàta**, Hort., white, with purple center, and var. **argéntea**, Hort., white fls., lilac stripes.

Subsp. **insígnis**, Brand. Baby Blue-Eyes. Fig. 2459. Lvs. pinnately parted into 7–9 oblong segms., which are sometimes 2–3-lobed or toothed: fls. ½–1 in. wide; corolla bright clear blue, the scales within its base short, partly free, covered with short hairs. Low ground, Calif. B.R. 1713. B.M. 3485. P.M. 3:151. V. 2:268; 5:168; 8:215. Gn. 74, p. 367.—There are many garden varieties. Among these are var. **grandiflòra**, with large, clear blue fls. (Gt. 34:370); var. **álba** fls. pure white; var. **marginàta**, or **variegàta**, Hort., fls. blue, edged with white.

Var. **crambeoìdes**, Hort. Corolla 15–18 in. diam., light blue, veined not spotted.

BB. *Fls. white; corolla-segms. each spotted deep purple.*

maculàta, Benth. Lvs. lyre-shaped, the 5–9 short lobes obtuse, entire; upper lvs. wedge-shaped, sometimes only 3-lobed: fls. white, with a deep purple blotch at the apex of each of the broad lobes, 1–2 in. wide, showy; sometimes the purple blotch is poorly defined. Common in W. and Cent. Calif. Blooms April and May. P.M. 16:6. F.S. 5:431. R.H. 1849:201. V. 2:267. J.H. III. 51:567.—Good garden forms of this are var. **álbida** and var. **grandiflòra**. Var. **variegàta** has variegated lvs.

S. W. Fletcher.
A. C. Hottes.†

NÉNGA (Malayan name). *Palmàceæ.* A few graceful spineless feather-leaved Malayan palms, one of which is cultivated as *Areca pumila.*

In Areca, the ovule is erect and fastened at the base, while Nenga belongs to a large group in which the ovule is attached on the side and more or less pendulous. Nenga is distinguished from the 5 cult. genera of this group (which are listed under Hedyscepe) by the following characteristics: staminate fls. with narrow sepals much surpassing the petals; stamens 6; anthers erect. Trunks erect, slender, ringed: lvs. terminal, equally pinnatisect; segms. linear, acuminate or obliquely 2-fid or 3-fid; margins folded back at the base; primary nerves sparsely scaly below; rachis 3-sided; petiole short; sheath cylindrical, strongly oblique at the throat: spadix with a short peduncle and slender pendent branches; spathes 2, the lower symmetrical, lanceolate, folded, 2-crested, the upper unsymmetrical, persistent, or lacking: bracts 3-fld.; bractlets scaly: fls. white: fr. ellipsoidal, smooth, reddish orange. Cult. as in Kentia.

Wendlandiàna, Scheff (*Arèca pùmila*, Blume). St. 10–20 ft. high, 2–3 in. diam.: lvs. 8–9 ft., pinnate nearly to the base; pinnæ alternate, ensiform, acuminate, 2½ ft. long, ½–1½ in. wide, bright green, coriaceous, 2-ribbed; petiole slender; sheath sub-ventricose, 2 ft. long. Java.

Jared G. Smith.

NEOBENTHÀMIA (in honor of Geo. Bentham). *Orchidàceæ.* Orchids with slender leafy sts.: fls. in racemes; sepals and petals similar, contracted, the lateral sepals forming a short chin with the column-foot; lip fleshy, entire, crisped on the margin; column short and thick; anther helm-shaped, upright; pollinia 2, with short stalks.—Species 1, in Zanzibar.

grácilis, Rolfe. Sts. up to 4 ft. long, sparingly branched: lvs. linear, acuminate, sheathing at base: fls. in a short terminal raceme, white, on long pedicels, campanulate; lip spreading from base, obovate-oblong, nearly truncate at apex, disk yellow in middle, with 2 rows of red spots. B.M. 7221. G.C. III. 10:273; 24:430, 431.—Cult. as for Cymbidium.

George. V. Nash.

NEOGLAZIÒVIA (*new Glaziovia*). *Bromeliàceæ.* Two Brazilian plants allied to Billbergia, but with ovules few rather than many in each locule. Plants terrestrial and on rocks, with spiny lvs. that furnish good fiber for ropes. *N. variegàta*, Mez (*Bromèlia variegàta*, Arr. *Billbérgia variegàta*, R. & S. *Dýckia Glaziòvii*, Baker), the Caroá of Brazil, is 3 ft. or more tall, with glabrous or very minutely lepidote lvs., marked with lighter transverse bars in the living specimen: fls. scarlet. *N. cóncolor*, C. H. Wright, the Makimbeira of Brazil, has a very short st.: lvs. uniformly white-lepidote, the younger parts woolly: calyx scarlet and petals violet. B.M. 8348.

NEÓGYNE (*new pistil*). *Orchidàceæ.* Pseudobulbous orchids with many-fld. racemes: fls. withering; sepals erect-connivent, free, saccate at base, longer and broader than the flat petals; lip concave, 3-lobed, saccate at base, the lateral lobes large, rounded, inclosing the column, the middle lobe small; column shorter than lateral lobes of lip, winged upward; anther dependent, convex; pollinia 4, waxy, dorsally compressed, the inner face deeply sulcate.—Species 1, native of the Himalayas.

Gardneriàna, Reichb. f. (*Cœlógyne Gardneriàna*, Lindl.). Lvs. narrowed into a petiole much shorter than pseudobulb, cuneate-elliptic, acuminate, up to 15 in. long and 3 in. wide: fls. white with a lip marked yellow, about 2 in. long. P.M. 6:73. G.W. 15, p. 86.—Cult. of warmhouse Cœlogyne; midwinter.

George V. Nash.

NEOLAÙCHEA (the type species flowered in the collection of Prince Johannes Liechtenstein, in honor of whose gardener, Herr Lauche, the genus was named). *Orchidàceæ.* One species, a native of Brazil, has been described. Primary sts. pro-repent, secondary sts. thickened into 1-lvd. pseudobulbs: infl. terminal; peduncle filiform, 1-fld.; pollinia 8. Closely allied to Cœlia.

pulchélla, Kränzl. (*Meiracýllium Wettsteìnii*, Porsch). A small plant with ovate pseudobulbs ⅖in. tall, terminated by a linear lf. 4 in. long, scarcely 1⅓ in. wide: peduncle shorter than the lf.; fl. purplish, about ⅖in. long; upper sepal and the petals lanceolate; lateral sepals coherent below the middle, free portion triangular; labellum with the lateral lobes minute, rounded, auriculæform; middle lobe rhombic; disk between the lobes thickened, minutely papillose. July.

Oakes Ames.

NEONICHOLSÒNIA (name in compliment to the late George Nicholson, curator at Kew, author of Dictionary of Gardening). *Palmàceæ.* Two Central American stemless palms with pinnate lvs. 4–6 ft. long, yet little known. Fls. monœcious; male fls. small, trifid, the petals 3 and longer than calyx, stamens connate at base in a short ring, the filaments subulate, anthers long-sagittate and with a thin subulate connective that forms a mucro beyond the apex, pistil a conical rudiment; infl. spicate: allied to Calyptrogyne. The genus is founded and the two species described by Dammer in G. C. III. 30, pp. 178, 179 (1901).

N. Geòrgei, Dammer, has lvs. about 4½ ft. long, petiole and all; pinnules 10 or 11 on each side the rachis, lanceolate, acuminate, with 1 central and 2 marginal primary nerves and 6–8 secondary nerves, 12–16 in. long and ⅓–2 in. broad, the first pair opposite and the others alternate, terminal pair confluent only at the base and 8 in. long by 1 in. broad. Costa Rica. *N. Wátsonii*, Dammer (named for W. Watson, Nicholson's successor at Kew), differs in its longer lvs., which are about 6 ft. long; and pinnules 9 or 10 on each side, elongate-lanceolate, caudate, 13–18 in. long and 1–2 in. broad, more or less opposite, the terminal pair confluent only at base and 10 in. long by 2 in. broad. Costa Rica.

L. H. B.

NEÓTTIA (meaning a *bird's nest*, and referring to the curiously interlaced roots). *Orchidàceæ.* A very few small terrestrial saprophytic orchids of Eu. and

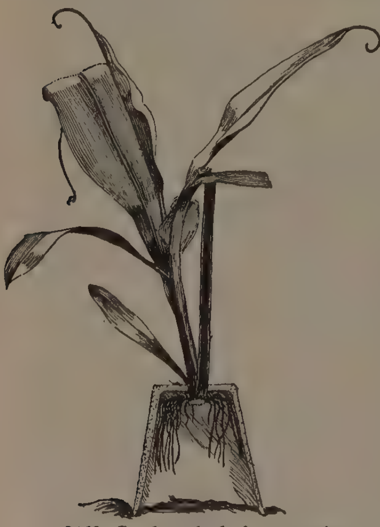
Asia, sometimes transferred to grounds, but little known as cult. plants. The *N. Petola*, Blume, of orchid collections, is *Macodes Petola*, which see. *N. speciosa*, Jacq., is Spiranthes, and *N. pubescens*, Willd., is *Goodyera pubescens*.

Leafless and brown, the st. with sheathing scales rather than lvs.: fls. brownish, in a raceme or spike; perianth hooded; lip deflexed and 2-lobed; column long and free, the anther hinged on the back of it. *N. Nìdus-àvis*, Linn., is the bird's-nest orchid of Great Britain and the continent, frequenting beech woods particularly: root a mass of interlaced stout fibers from the extremities of which young plants are produced: st. 12–18 in. high: fls. many in a dense spike ⅓in. long, with short bracts. L. H. B.

NEOTTÓPTERIS (name means *bird's-nest fern*). *Asplenium Nidus*, of which *N. australasicum* is by botanists considered to be a synonym, although by others kept distinct. *A. Nidus* is widespread in Tropical Asia and the Pacific Islands, and is a most striking large fern. B.M. 3101. G. 13:85, where distinctions are made between *N. australasicum* and *N. Nidus*.

NEPÉNTHES (from Greek for *without*, and *care*). *Nepenthàceæ*, the only genus of the family. The genus includes those forms that are popularly called PITCHER-PLANTS, and consists of about seventy species, all of which are found in the Orient. The generic name was given in allusion to the statement in the "Odyssey," where Helen so drugged the wine-cup that its contents freed men from care and grief. Linnæus in naming the genus truly expressed the feeling that some travelers have since experienced when he said "If this is not Helen's Nepenthes, it certainly will be for all botanists. What botanist would not be filled with admiration, if after a long journey he should find this wonderful plant? In his astonishment past ills would be forgotten when beholding this admirable work of the Creator."

All of the nepenthes are climbing or rarely upright plants of rather straggling habit and semi-woody consistence. In height they vary from a foot to 60 or 70 feet, while the stem varies from the thickness of a pencil to an inch across. In their native haunts the plants spread their rootage abundantly through the decaying humus of moist "scrub" land, and when planted in an open greenhouse border, they grow equally vigorously. But the roots always spread near the surface, and free oxygen exchange is necessary. Some of the more striking species, like *N. Veitchii* and *N. Edwardsiana*, are often or habitually epiphytic. The former has become so adapted to this mode of life, that its stem creeps horizontally or obliquely upward along tree branches, while the leaves with their yellow-green pitchers spread in double rows on either side. Such forms, therefore, succeed only under cultivation when treated like the epiphytic orchids. Well-known species, like *N. ampullaria* and *N. Rafflesiana*, may form long rope-like stems amid the rather open forest vegetation of their native haunts, and then spread out amongst the tree crowns, there to bear the graceful pitchers and the racemes of nectariferous flowers. These latter, according to Burbidge, are often encircled by groups of insects.



2460. Good method of propagating nepenthes.

The cutting is placed in an inverted pot. The stick at the right wedges the cutting and keeps it tight; it may also carry the label. The pot is cut in two vertically to show how the roots form in the air, without the aid of sand, water or even moss.

Each fully developed leaf is of complicated structure. It may be either sessile or stalked, but always has a lower flattened blade portion, that is traversed lengthwise by two to ten or twelve veins, all of which are braced together in turn by transverse or oblique nerves. The number and disposition of the former yield valuable aid in classification of the species. The midrib is then prolonged as a tendril of varying length, but of great tenacity. This can wind around supports, and alike helps the stem in bearing the crown of leaves, and supports the pitchers with their often considerable weight of water.

The pitcher is the greatly expanded and hollowed-out end of the midrib. It usually bears two fringed or ciliate wings in front, that in the seedling leaf are continuous with the blade below, and gradually become separated from it as older leaves are produced. They represent, therefore, lobes that are separated off from the blade portion in the early history of the leaves. The margin of each pitcher, except in *N. Lowii* (Fig. 2462), is widened or thickened without and within into a collar-like rim or peristome, that is striated, corrugated or even ridged from within outward, and is of shining aspect. The inner, or the outer, or both rim-margins may be curved downward and inward, so as to give a cylindric aspect to the peristome (Fig. 2463), or it may be widely expanded as a spreading collar (Fig. 2465). The pitchered or hollowed-out midrib ends in a small spur at the back of the peristome, and just behind the insertion of the lid that next deserves notice. This lid represents two terminal lobes of the leaf formed on either side of the spur, and which have grown forward, have fused, and so have caused the lid to be traversed by two main veins from which minor ones may branch off.

All of the above details would be comparatively unintelligible did we not refer shortly now to the numerous secreting glands that are formed over the leaf, and to the function of these in securing the capture and digestion of insects or other prey. Over the lower blade surface, here and there along the tendril, over the pitcher and lid exterior, but most abundantly over the inner lid surface, small spots can readily be detected that exude a honied juice. This is greedily licked by ants, cockroaches, and other—mostly running—insects. They are thus attracted to the edge of the peristome, or upward to the inner lid surface with its rich nectar supplies. In either case they usually step ultimately on the shining surface of the peristome. But the finely or coarsely serrated inner edge of this carries the openings of large sunken glands. These exude a juice that is greatly liked by insects. In attempting to reach the droplets they often slide off into the pitcher interior. This shows a different but equally noteworthy device. In some species, like the commonly grown *N. ampullaria*, *N. Hookeriana* and *N. Chelsonii*, the entire pitcher interior is smooth and glistening, but abundantly studded with small glands that excrete an acid peptonizing fluid, capable of converting albuminous substances like animal flesh or white of egg into a dissolved peptone or even into a simpler tryptophan product that can readily be absorbed and assimilated by the inner pitcher wall.

In most species and hybrids, however, now under cultivation, the upper one-third or one-half, of the pitcher interior is extremely smooth and bluish or purplish waxy in aspect. This forms a sliding or "conducting" surface, that ensures dropping of insects into the lower area, where digestive glands occur as already described. So following the nomenclature of Hooker and the writer, the general external leaf area with its scattered honey-glands forms the "alluring" surface. The inner lid area and the peristome rim with their concentrated honey-glands, form the "attractive" surface, the smooth upper part of the interior that is devoid of glands can well be named the "conducting" surface, while the glistening lower area with its abundant digestive glands, forms the "detentive" and digestive surface.

In greenhouses where ants and cockroaches occur, the captured prey soon accumulate in such pitchers as *N. hybrida*, *N. Hookeriana* or *N. khasiana*, at times also to such an extent that the ammoniacal fumes of the decaying contents cause a brown discoloring of the pitcher-wall. The loose stuffing, therefore, of the pitchers with wadding or moss has been recommended by some growers. But it appears certain that the pitchers are thereby prevented from securing, digesting, and absorbing animal prey that seems to aid in the nutrition of the plant under wild as under cultivated conditions.

Another feature deserves mention here from the cultural and physiological standpoints. The leaves bear an abundance of minute brown peltate hairs, that appear to the naked eye as dark specks. Even though nepenthes be almost wholly deprived for a time of their roots, the plants remain healthy if kept in a moist atmosphere. This and other evidence, that cannot here be cited, suggest that atmospheric moisture may be absorbed directly through the leaf surface, though such a view is contrary to current physiological opinion.

In contrast to the above relations, it has been shown by three observers that several species of insects and also a spider are capable of living, and even, in some cases, of breeding, in the pitcher liquid, while they are able with impunity to ascend and pass out from the pitcher cavity. Their ability to live in the pitcher liquid that digests other insects seems to be due to their having an antagonistic or neutralizing ferment to that in the pitchers.

The size, shape, and color-markings of the pitchers vary greatly. The pitchers of the rare *N. bicalcarata* are usually yellow-green, but may be of a faint brick-red. Projecting downward from the top of its high neck and so overhanging the pitcher-cavity are two strong sharp spines. These have been considered by Burbidge to act as protective spines against the thieving habits of a small lemur (*Tarsius spectrum*) that attempts to rifle the pitchers of their insect prey. When it tries the above it is often caught by the nape of the neck, and tumbled into the pitcher. Equally curious in the same species is the thickened end of the tendril alongside the pitcher, that is always thickened, and in the wild state is drilled by ants which form a home or myrmicarium in the interior.

N. Lowii (Fig. 2462) has large leathery urnshaped pitchers of a greenish yellow hue, each strongly constricted in the middle, and so in outline resembling the finely colored *N. ventricosa* and *N. Burkei*, now in cultivation from the Philippines. *N. Rajah*, found about 6,000 feet on Kinabalu only, attains a height of 5 to 6 feet, but its huge claret-crimson goblet pitchers sit in the moist moss of the ground at the ends of the large dependent leaves which spread out from the stout stem. *N. villosa* and *N. Edwardsiana* are soil-growers or often epiphytes with brilliant crimson pitchers of striking aspect that grow on Kinabalu at 8,000 to 10,000 feet elevation. Two splendid new species, *N. Merrilliana* and *N. truncata*, have recently been described from the Philippines, which suggests that these islands may yet yield other attractive types.

The flowers appear in panicled or simple racemes on the young wood, and each raceme is opposite a bract-leaf that differs usually in shape and venation from the other foliage-leaves. In greenhouses of the north-eastern states, these inflorescences appear as a rule, from July to October, but only on plants or on shoots that have been allowed to grow long. Thus racemes appear on *N. maxima* (*N. Curtisii*), *N. Hookeriana*, and *N. phyllamphora* when the shoots are from 5 to 12 feet long. The plants are always diœcious, and so for production of seeds under cultivation a staminate and pistillate plant must be in bloom simultaneously. Failing this, it has been shown experimentally that pollen from a staminate plant can be kept good for days or even weeks, if preserved in tinfoil or in paraffin paper and in a cool place. Taplin adopted this method in order to secure some of his fine hybrids, while *N. Dicksoniana* (page 2128) was got in the Edinburgh Botanic Garden from the seed-parent *N. Rafflesiana*, by applying to it pollen of *N. Veitchii* forwarded from the Veitch establishment in London.

2461. A simple propagating-frame. Used by Robert Shore for propagating nepenthes, dracenas and other tropical subjects.

The staminate flowers are produced in dense paniculate cymes as in *N. ampullaria*, or in loose simple racemes as in *N. gracilis* and *N. sanguinea*. Each consists of four green, yellowish, red or claret-colored sepals, about ⅜ by ¼ inch in size on the average, and of rather thick texture. The inner surface is closely dotted over with honey-glands that resemble the attractive lid-glands, and which pour out an abundant nectar secretion at the time of blooming. This is often accompanied by a heavy somewhat fetid odor, and the two attractions draw small insects in great numbers to the flowers. Becoming dusted with pollen they carry this to pistillate flowers on other plants. The stamens rarely may be from twenty to twelve in number, commonly they are from ten to eight, or they may be as few as four. The filaments are fused into a short pillar that bears the terminal anthers in a rounded crowded mass. When the latter dehisce the whole appears as a dusty ball of pollen.

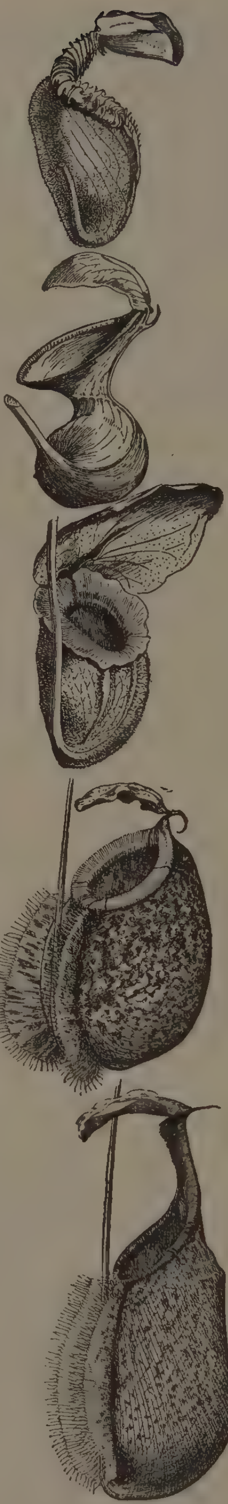
The pistillate flowers bear sepals like those of the staminate. The pistil consists of four carpels that are united below to form a four-celled ovary. This incloses many minute elongated ovules, which after fertilization continue to lengthen, and swell up in the middle to form the seeds. The style is either very short and thick, or is practically absent. The stigma is four-lobed to rounded, and forms an expanded thickened mass on top of the short style or of the ovary. It, as well as the sepals, persists during maturation of the fruit. The fruit when ripe is a dry glabrous and shining or a hairy capsule that dehisces loculicidally into four valves. The seeds vary in number, according to the species, from 100 to 500 in a capsule. Each is a light delicate elongated thread-like body, due to great elongation of the loose seed-coat on either end of the central mass. From their extreme lightness they can readily be blown to considerable distances, and this fact, along with the direction of the prevailing monsoon winds, seems to explain the distribution of the species along the western and northwestern sides of the foothills or the mountains where they mainly occur.

The literature of the group has been recently summarized by the writer in his monograph published as hft. 36 of Engler's "Pflanzenreich." A general description is there given in English on pp. 2–26, while detailed descriptions of the species and hybrids follow in Latin. An interesting account of the group is given by Veitch and Burbidge in Journ. Roy. Hort. Soc., vol. 21 for 1897, on pp. 226–262.

History and distribution.

We owe the first notice of the group to the French botanist Flacourt. In his "History of the Island of Madagascar" (1658) he described the only native pitcher-plant of that region as Anramitico, and inclined to regard the pitcher as a flower or hollow fruit. In 1679 Breyn described the only Ceylon species as *Bandura Zingalensium*, and he justly regarded it as a vegetable wonder. Since that time other forms have been discovered in the Seychelle Islands, in southern China, in northeast India, in the Philippines, the East Indian Islands and in northeast Australia. But the headquarters of the genus extend from the Malay Peninsula—where are ten species—through Borneo and Sumatra, that contain about twenty-four species, to New Guinea and Australia in a southerly and the Philippines in a northerly direction, where are about twenty-six species.

While nearly one-fourth of the species grow in hot reeking swampy situations at or near sea-level in the eastern tropics, the larger number occur in moist ground on the western and northwestern sides of the mountains at elevations of 1,000 to even 10,000 feet. Thus the lone and impressive mountain, Kinabalu in northwestern Borneo, that rises to a height of 13,700 feet, overlooks a tropical shore region that is rich in nepenthes. But, from 3,000 to 10,000 feet, it harbors eight species, some of which are the largest and most gorgeously colored of the genus. The zone of the mountain where the finest are found extends from 6,000 to 10,000 feet and Burbidge has graphically described how this entire belt is almost continuously shrouded in a dense mist, due to moisture precipitation from meeting of the hot lower current of air with the cold currents from the mountain top. This moist dripping climate seems eminently to suit the forms found there, while all of the species flourish best when kept in moist "steamy" surroundings. Repeated attempts were made, from 1750 onward, to introduce and grow a few of the species from Madagascar, Ceylon, India and Borneo. But the type of greenhouse of this earlier period, and the method adopted in their cultivation combined to prevent success. From 1830 to 1860, however, so well had the mode of culture advanced, that seedlings were raised in the Edinburgh, London and Chatsworth gardens, while the Veitch firm that now had collectors like Lobb busy in the native haunts of the genus, imported living plants as well as seeds, both of which they grew successfully. A great impetus was given to the culture of the group when gardeners like Dominy, Taplin, Seden and Court succeeded in crossing some of the species then cultivated, from 1850 to 1870, and in raising hybrids therefrom. These hybrids seemed often to combine good points of both parents, while they, as well as many hybrids since secured, are usually more easy of cultivation, and form a greater showing of the striking pitchers than does either parent. But a new and very lively interest was created in the group after Hooker drew attention to the remarkable structure of the pitchers, and their adaptation to the catching and digestion of insect prey, as set forth in his Belfast address before the British Association in 1874. Collectors like Curtis, Burke, and Burbidge were commissioned by the Veitch firm to secure every available type encountered from Madagascar to Australia. Successful methods of raising, growing and flowering these had been devised; numerous new hybrids appeared in England, America and France from 1875 to 1900, while the scientific interest in the group that was stimulated by the writings of Darwin and Hooker has caused an ever-increasing demand for such plants in every typical collection.



2462. Five distinct types of nepenthes. Beginning from the top they are: *N. villosa*, *N. Lowii*, *N. Rajah*, *N. Hookeriana*, and *N. Rafflesiana*. The first three belong to the famous Kinabalu group. The fourth is the parent of more hybrids than any other kind.

A description of the nepenthes would be very incomplete in such a work as the present, did we not refer again to the history of their hybridization by man, and the resulting production of hothouse types that more than rival in beauty many of the wild species, and which are, as already indicated, more easy of cultivation than are the parent forms.

When Dominy first attempted to cross Nepenthes, few fine forms were in cultivation, *N. Rafflesiana* and *N. Hookeriana* being the best. About 1858 or 1860 he crossed flowers of the former with pollen from what was probably *N. gracilis* from Borneo. The resulting hybrids that were sent out from the Veitch nurseries as *N. Dominii* were at once a success under cultivation, and stimulated further experiment with species of the group. Dominy, Seden, Court and Outram continued this in England from 1860 to 1880, while Taplin, a friend of the two latter, extended the work in Such's collection. By the latter period it had been proved that the species of Nepenthes can be hybridized and rehybridized, at the same time remaining fertile. The varied beauty and easy culture of the hybrids—specially those of Taplin, which were secured and distributed mainly by Williams of London, rendered the group more popular. An added stimulus was given when Court raised *N. Mastersiana* about 1880. But such striking species as *N. Veitchii*, *N. Northiana*, *N. maxima*, (*N. Curtisii*) and *N. sanguinea* were all soon to hand, and so hybridizers like Court, Tivey, Lindsay, and Gautier in Europe, as well as Oliver and Siebrecht in this country, produced novelties in which the "blood" of three to four species was blended. In France, Jarry-Desloges and his gardener have obtained some beautiful and complex hybrids, but they have not as yet been distributed.

The pitchers of some of the above when well grown are magnificent, the plants are in no way more difficult of culture than many of the well-known orchids, while the climatic conditions of America, when modified by moist stovehouse treatment, seem eminently to favor vigorous growth. They have therefore become familiar objects in many American greenhouse collections during the past decade.

All of the species now in cultivation hybridize readily with each other, and produce abundant as well as good seeds. These should be sown on the surface of a seed-pan that is filled with a finely chopped mixture of sphagnum, pot crocks and charcoal. A bell-jar should cover the pan, and it should then be set in a plate of water to ensure a steamy atmosphere. Germination occurs in two to four weeks. The seedlings should be potted off into thumbs when about a month old, and then changed every two months into larger pots. Well-grown year-old plants begin to show adult characters.

Nepenthes culture. (G. W. Oliver.)

Nepenthes are increased by cuttings and by seeds. The ripened shoots, with four or five leaves attached, make the best cuttings. They may be rooted from December till the end of January, but under proper conditions the operation may be performed at any time during the year. Some of the free-rooting kinds, such as *N. Dominii*, *N. gracilis*, *N. Phyllamphora* and *N. Mastersiana*, may be rooted in sand under a glass with a little moss tied around the base of each cutting. Under this treatment the temperature of the sand should be about 80° F. When the roots show through the moss they should be put in small pots and kept close for a couple of weeks. The most satisfactory method of propagation is to put the base of each cutting through the hole of an inverted 2-inch rose pot, plunging the pot in sphagnum moss in a temperature from 80° to 90°. F. (See Fig. 2460.) During the operation of rooting they must be kept in a close propagating-frame and frequently syringed. (See Fig. 2461.) When the roots are about ¾ inch long the cuttings should be potted, using a mixture of finely chopped fibrous peat, moss and sand, with a little finely broken charcoal added. They should be replaced in the moss and kept close until the pots are fairly well filled with roots and then gradually hardened off. All of the kinds do best suspended from the roof of a hothouse, the temperature of which should not fall below 65° F. in winter. The plants may be grown either in orchid-pots or -baskets. In potting or basketing plants from 4-inch pots, large pieces of potsherd and charcoal should be firmly placed here and there among the potting material, which should consist of rough fibrous peat, moss and sand. The plants should not be allowed to grow as vines unless they are intended to produce seed. When large-sized pitchers are wanted, the ends of the shoots should be nipped out after several leaves have been made and the pitchers are in the process of development; this throws strength into the last-formed leaves and produces very large pitchers. When the plants are in active growth they should be well drenched with water at least once each day and syringed frequently, but care should be taken not to overwater newly potted specimens. They should at all times be shaded from bright sunshine, and when a house is devoted to them, or partly occupied with plants requiring similar treatment, it should be shaded with cloth fixed to rollers. Well-pitchered plants may be taken from the growing house and exhibited in good presentation for a long time in a house under conditions which would be unfavorable for their growth. All of the hybrid forms are of easy culture. *N. Mastersiana*, *N. Dominii*, *N. Outramiana* and *N. Henryana* produce pitchers very freely. The species, as a rule, are not quite so free, but some of them thrive equally as well as the garden forms. *N. Rajah*, *N. Northiana*, *N. sanguinea*, *N. albo-marginata* and *N. bicalcarata* are all more or less difficult to manage, as the conditions under which they grow in their native haunts are sometimes not easily imitated. *N. ampullaria*, *N. Rafflesiana*, *N. Phyllamphora*, *N. distillatoria* and *N. Kennedyana* are usually seen well furnished with good pitchers.

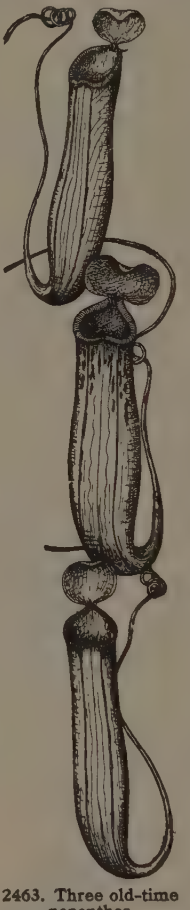
KEY TO THE SPECIES.

A. *Pitcher-lid small, reflexed*.......... 1. **ampullaria**
AA. *Pitcher-lid well developed, inflexed over orifice.*
  B. *Lid devoid of keel, spur, or bristles within.*
    C. *Longitudinal veins of lamina 2–4: lvs. sessile.*
      D. *Collar below peristome white-tomentose*.................. 2. **albomarginata**
      DD. *Collar below peristome brownish tomentose.*
        E. *Lvs. decurrent.*
          F. *Peristome broadly expanded, purplish green or purple striped*...... 3. **cincta**
          FF. *Peristome expanded, green and red-striped*........ 4. **Northiana**
          FFF. *Peristome expanded, purple*.................. 5. **mixta**
        EE. *Lvs. non-decurrent.*
          F. *Peristome red*.......... 6. **sanguinea**
          FF. *Peristome crimson to purple*.................. 7. **Mastersiana**
    CC. *Longitudinal veins of lamina 2–4: lvs. stalked.*
      D. *Peristome deeply ridged; pitchers pyriform*.......... 8. **villosa**
      DD. *Peristome deeply ridged; pitchers elongate-tubular*.... 9. **Edwardsiana**
    CCC. *Longitudinal veins of lamina 5–6: lvs. sessile, non-decurrent.*
      D. *Pitchers strongly constricted in middle, mouth transverse*....10. **ventricosa**
      DD. *Pitchers strongly constricted in middle, mouth oblique*.......11. **Burkei**
      DDD. *Pitchers large, oval*..........12. **Merrilliana**
    CCCC. *Longitudinal veins of lamina 5–6: lvs. sessile, decurrent.*
      D. *St. slender trigonous: peristome narrow-oblique*.......13. **gracilis**
      DD. *St. stout cylindric: peristome rounded, oblique*...........14. **khasiana**
      DDD. *St. stout cylindric: peristome elevated into short neck*......15. **Sedenii**
    CCCCC. *Longitudinal veins of lamina 5–6: lvs. petiolate.*
      D. *Pitchers green, reddish or slightly purple-spotted.*
        E. *Lvs. herbaceous: peristome green, cylindric*.........16. **distillatoria**
        EE. *Lvs. coriaceous: peristome green, cylindric*.........17. **hybrida**
        EEE. *Lvs. coriaceous: peristome expanded*...............18. **cylindrica**
      DD. *Pitchers richly green and purple-blotched; peristome pale green, oblique,*

E. *Color of pitchers throughout purple-blotched*..........19. **Dormanniana**
EE. *Color of pitchers below purple-red, above purple-blotched*................20. **paradisæ**
DDD. *Pitchers green and purple-blotched; peristome oblique, green and purple-striped.*
E. *Color of pitchers red-purple with pale green spots*......21. **atrosanguinea**
EE. *Color of pitchers green with heavy purple marblings.*
F. *Pitcher-wings narrowing from below upward, fringed*...............22. **Dominii**
FF. *Pitcher-wings broad, uniform*.................23. **excelsior**
FFF. *Pitcher-wings broad, doubly fringed*........24. **Hookeriana**
FFFF. *Pitcher-wings of various forms.*
G. *Lf.-margins ciliate-toothed*............25. **Lawrenciana**
GG. *Lf.-margins hairy: pitchers yellow-green with abundant red spots*..............26. **Outramiana**
GGG. *Lf.-margins plain: pitchers yellow-red to red with fine crimson-purple spots*........27. **Williamsii**
DDDD. *Pitchers like* DDD, *but peristome more or less elevated behind into a neck, or widely expanded.*
E. *Peristome elevated into a slight neck behind*........28. **Chelsonii**
EE. *Peristome elevated into a high neck behind*.........29. **intermedia**
EEE. *Peristome elevated into a high widening neck*......30. **Rafflesiana**
EEEE. *Peristome oblique, widely expanded laterally*.......31. **Dicksoniana**
EEEEE. *Peristome expanded, elevated into a neck behind*...32. **edinensis**
CCCCCC. *Longitudinal veins of lamina 7–12: lvs. stalked.*
D. *Lvs. non-decurrent.*
E. *Pitcher-wings narrow or nerved*.................33. **Phyllamphora**
EE. *Pitcher-wings prominent*..34. **coccinea**
DD. *Lvs. slightly decurrent.*
E. *St. finally glabrous: pitcher-wings expanded*.........35. **Kennedyana**
EE. *St. hairy*.................36. **Rowanæ**
DDD. *Lvs. decurrent.*
E. *The lvs. greenish red or red below*..................37. **madagascariensis**
EE. *The lvs. of a peculiar dark green: two strong peristome spines below lid*..........38. **bicalcarata**
BB. *Lid with keel, spur or bristles within*
C. *The lid with basal keel only.*
D. *Lvs. hairy.*
E. *Color of pitchers yellow or greenish red*.............39. **Veitchii**
EE. *Color of pitchers yellowish green with purple spots: lamina usually peltate*....43. **Dyeriana**
DD. *Lvs. glabrous (except margin in N. Wittei).*
E. *Pitchers green, purple-spotted*.................40. **alata**
EE. *Pitchers crimson-purple*....41. **Rajah**
EEE. *Pitchers brownish red, purple-spotted*..............42. **nobilis**
EEEE. *Pitchers tubular, pale green*..44. **Wittei**
EEEEE. *Pitchers crimson: lvs. truncate at both ends*.........45. **truncata**
CC. *The lid with median keel only*....46. **stenophylla**
CCC. *The lid with basal keel and subapical spur.*
D. *St. glabrous*................47. **maxima**
DD. *St. hairy*...................48. **Tiveyi**
CCCC. *The lid with apical spur only*....49. **Balfouriana**
CCCCC. *The lid with long rough bristle hairs within*................50. **Lowii**
CCCCCC. *The lid with shining bristle hairs within*.....................51. **Macfarlanei**

1. **ampullària,** Jack. Bright green, st. and lvs. when young rusty-hairy: pitchers small, green or with few purple spots; peristome broad, obliquely inclined inward; lid small, reflexed. Malaya, Sumatra, Borneo, New Guinea. B.M. 5109. I.H. 24:272. F.S. 22:2325.—An interesting type, easy of growth, and often producing clusters of small pitchers.

2. **álbo-marginàta,** Lobb. St. and lvs. white-tomentose when young: pitchers tubular, dull green with abundant purple blotches or areolations; peristome bounded below externally by a white collar. Malaya, Sumatra, Borneo. G.C. 1872:541. 542. F.S. 22:2343, 2344.—Grows in stiff moist clay in native home (Burbidge), but difficult under cult. A variety with deep purple pitchers is grown as *N. álbocíncta* var. *rùbra.*



2463. Three old-time nepenthes.
Much confused in collections and difficult to distinguish: *N. phyllamphora* above, *N. khasiana* in the middle, *N. distillatoria* below.

3. **cíncta,** Mast. (*N. Northiàna* × *N. álbo-marginàta*). Lvs. thick, deeply amplexicaul, decurrent: pitchers 3–10 x 1–3 in., dimorphic, lower ventricose in inferior, cylindric in superior half, upper cylindric to funnel-shaped, green flushed with red and richly purple-blotched; peristome bounded below by brownish white felted collar. G.C. II. 21: 576. R.B. 21, pp. 268, 269. Gn. W. 4:101.—A vigorous and striking natural hybrid got from seeds collected by Burke. In all characters nearly intermediate between parents.

4. **Northiàna,** Hook. f. (*N. spùria,* Beck). Robust, bright green: lvs. amplexicaul, deeply decurrent, sessile, thick herbaceous, apex peltate: pitchers 3–14 x 1–4 in., dimorphic; lower sub-ovate, pale green with purple spots, upper funnel-shaped with recurved base, richly purple-spotted; peristome widely expanded. Borneo. G.C. II. 16:717. Gn. 23: 492 (as *N. Morganiae*). J.H.S. 21: 236. Gn.W. 4:105. J.H. III. 44:127.—Difficult of growth but with lovely large pitchers. It has been used as parent for some fine hybrids.

5. **míxta,** Mast. (*N. Northiàna* × *N. máxima*). Lvs. amplexicaul, deeply decurrent, petiolate, elliptic with peltate apex: pitchers 3–12 x 1½–3½ in., ventricose-cylindric, yellow-green and sparsely purple-spotted below, abundantly flecked with large spots above; wings narrow, or absent below, expanded and fringed higher; peristome rich purple. G.C. III. 13:47. G.Z. 20:145. G.M. 36:754. F.E. 16:447. G.W. 10:527; 14:293.—One of Tivey's best hybrids that makes a strong growth, flowers readily, and has been a parent for some even finer hybrids.

6. **sanguínea,** Lindl. Lvs. sessile, deeply amplexicaul, thick, herbaceous, oblong-lanceolate: pitchers 3–10 x 2–3 in., ventricose-cylindric to cylindric, bright red to reddish green, wings expanded fringed, or narrow plain; peristome laterally expanded. G.C. 1849:580; 1872:541. F.S. 22:2343. F.M. 1874:128. Gn.W. 24:

504.—Sent about 1849 from Malaya by Lobb to England. but cult. difficult. It yielded the hybrid *N. Mastersiana*, but is now rare in cult.

7. **Mastersiàna,** Veitch (*N. sanguínea* × *N. khasiàna*). Lvs. sessile, slightly decurrent, glabrous, shining: pitchers 5–15 x 1½–3 in., crimson-green with purple spots to uniformly deep crimson; wings fringed or rudimentary; peristome crimson-green to crimson. G.C. 21:248, 249. Gn. 23:492. G.W. 9:285. I.H. 33: 618. J.H.S. 21:237.—A beautiful and easily grown hybrid of Court, but which varies greatly in pitcher-coloring.

8. **villòsa,** Hook. f. Fig. 2462. This is distinct from all other species here described by its rim, which is composed of distant disks that are circular except for teeth which project down into the pitcher.

9. **Edwardsiàna,** Hook. f. This and the last are probably the most striking species of the genus. Both are figured in color by Spencer St. John in Life in Forests of Far East, also by Hooker in Trans. Linn. Soc. 22:69, 70. The former has a short urn-shaped, this a long cylindric pitcher. Neither has as yet been cult. Borneo.

10. **ventricòsa,** Blanco. Terrestrial or epiphytic: lvs. thick, aggregate round st., sessile, shortly decurrent, linear to lanceolate: pitchers in aspect as in *N. Burkei* but mouth elliptic in outline and transverse; lid with 3 to 4 pairs of veins. G.C. III. 23:379. Gn. 74, p. 647. G.M. 44:691. J.H. III. 43:486.—Near to though distinct from *N. Burkei*, but both are native to the Philippines. It flourishes fairly well under cool moist treatment.

11. **Búrkei,** Mast. Lvs. sessile, slightly decurrent, aggregate round st., linear-lanceolate, slightly contracted above insertion: pitchers 3–6 x 1–2½ in., dimorphic, lower cylindric-ventricose, upper constricted in middle, ventricose below, widening above; mouth ovate-oblique, wings absent, surface pale green or with few purple blotches below, heavily blotched above; lid equal to or larger than mouth, with 6–7 pairs of veins. Mindoro in Philippine Isls. Var. **éxcellens,** Veitch, has short wide pitchers richly purple-tinted with dark purple blotches. G.C. III. 6: 493; 8:184, desc. Gn. W. 7:137; 11:153.—This is a species that pitchers abundantly if kept cut back.

12. **Merrilliàna,** Macfarlane. A Philippine species with large crimson-green pitchers, that when intro. may prove valuable for hybridization. Recently described by the author in Bot. Contrib. Univ. Penn. 3:207, pl. 1.

13. **grácilis,** Korthals. Plant slender with green to dull red st.: lvs. sessile, decurrent, elliptic, glabrous, veins 5–7: pitchers 2–4 x ½–1 in., pale green with delicate purple flecks or spots, lower cylindric-ventricose with fringed wings, upper cylindric with narrow wings or ridges; peristome narrow green. G.C. 1872:542, desc.—A weedy species of easy cult., but shy in producing its delicate pitchers. It grows in marshy areas in Malaya, Borneo and Sumatra.

14. **khasiàna,** Hook. f. Fig. 2463. Lvs. sessile, lanceolate: pitchers 3–7 x 1–1½ in., elongate, tubular, green to reddish green with narrow fringed wings; peristome green, cylindric; lid oval, green outside, reddish green inside. B.M. 2629 (as *N. Phyllamphora*); 2798 (as *N. distillatoria*).—Early intro. into cult. from the Khasia Mts. of E. Hindostan, but now rarely seen. It forms shoots 30–40 ft. long with abundant long green pitchers.

15. **Sèdenii,** Mast. (*N.* ? × *N. khasiàna*). Lvs. half-amplexicaul, decurrent, lanceolate, glabrous: pitchers 3–5 x 1–2 in., ventricose below, constricted in middle, cylindric above; wings fringed; peristome cylindric, elevated somewhat into a neck behind. G.C. 1872:542, desc. F.W. 1870:321. F. 1872:54. J.H.S. 21:237.—A hybrid of Seden's that is often and well grown in American greenhouses.

16. **distillatòria,** Linn. (*N. índica,* Poir. *N. zeylánica,* Raf. *N. hirsùta* var. *glabréscens,* Smith. *N. rùbra,* Nichols. *N. zeylánica* var. *rùbra,* Beck. *N. speciòsa,* Hort.). Fig. 2463. Plant bright green, rather slender: lvs. petiolate, half-amplexicaul, glabrous, elliptic-elongate: pitchers 3–5 x 1–1½ in., dimorphic, pale green to dull crimson, lower ventricose below, tubular above; wings wide, fringed, narrowed from below up; mouth nearly transverse; upper cylindric, wings rudimentary, mouth oblique with short posterior neck; peristome cylindric green. P.M. 4:1. L.B.C. 11:1017.—A somewhat unattractive species from Ceylon, that has been a parent of several hybrids.

17. **hýbrida,** Mast. (*N. khasiàna* × *N. grácilis*?). Lvs. amplexicaul, decurrent, semi-petiolate, elongate-lanceolate: pitchers 3–5 x ¾–1 in., cylindric, slightly constricted in middle, green or somewhat purple-spotted (var. *maculàta*); wings shallow ciliate. G.C. 1872:542, desc. J.H.S. 21:1897:238.—A hardy freely pitchering though rather unattractive type that usually catches abundant insect prey in greenhouses. Raised by Dominy about 1863, and sent out by Veitch in 1866.

18. **cylíndrica,** Veitch (*N. distillatòria* × *N. Veìtchii*). St. ascending: lvs. obovate or oblanceolate with reddish midrib: pitchers 5–7 x 1–2 in., ovate-elongate or sub-cylindric, pale green with few small purple spots; wings narrow, interrupted below, fringed above; peristome expanded, yellow-green. G.C III. 2:521.—A rather unattractive hybrid that is now rare in cult.

19. **Dormanniàna,** Williams (? *N. Phyllámphora* × *N. Sédenii*). Lvs. elliptic-lanceolate, margin finely ciliate, veins 5–6: pitchers 4–6 x 2–2½ in., cylindric-ventricose, green and purple-blotched; wings fringed or dentate, narrowed upward; peristome pale green. G.C. II. 17: 525. Gn. 27:496.—A pretty hybrid of doubtful parentage that was raised by Taplin and sent out by Williams.

20. **paradìsæ,** Hort. Parents probably similar to *N. Lawrenciana*, but pitchers richly purple-red below, yellow-spotted above.—Sent out by Williams in 1883.

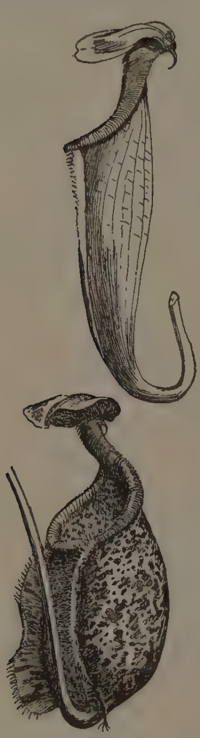
21. **atrosanguínea,** Mast. (? *N. distillatòria* × *N. Sédenii*). Pitchers ventricose below, cylindric above, reddish purple with pale green mottlings; wings fringed wide below, gradually narrowed above; peristome cylindric, oblique, pale green and purple-striped. G.C. II. 17:827.—A Taplin hybrid that grows readily and pitchers freely if kept cut back.

22. **Dóminii,** Veitch (*N. Rafflesiàna* × ? Bornean sp. probably *N. grácilis*). St. dark red: lvs. amplexicaul, decurrent, petiolate, lanceolate: pitchers 3–5 x 1–2 in., ventricose below, contracted toward mouth, mottled green and dark purple; wings narrowing from below upward, fringed; peristome uniform, elevated into a neck behind. J.H.S. 21:238.—This, the first artificial hybrid, was raised by Dominy about 1860, and is still a favorite of easy cult.

23. **excélsior,** Williams (*N. Rafflesiàna* × *N. Hookeriàna*). St. and lvs. at first densely tomentose-pubescent, at length glabrous: lvs. petiolate elliptic: pitchers cylindric-ventricose, pale green with deep purple spots and blotches; wings wide, fringed; peristome cylindric, elevated into a neck behind.—Amongst the best of Taplin's hybrids, as the pitchers are freely produced and are sharply marked, while the plant grows well and prop. readily. *N. amábilis* and *N. Amesiàna* have the same parentage and are nearly related in aspect.

24. **Hookeriàna,** Lindl. (*N. Loddígesii,* Baxter. *N. Hoòkeri,* Alphand). Fig. 2462. Plants strong, young parts covered with brownish white pubescence: lvs. amplexicaul, petiolate, elliptic-lanceolate, veins 5 with

radiating nerves: pitchers 2–5 x 1–3 in., dimorphic; lower subglobose, pale green with extensive purple blotchings; wings ample, doubly fringed; upper funnel-shaped wings narrow not fringed, mouth oblique elevated into a neck behind. G.C. II. 16:813. I.H. 41, p. 145. G.W. 2:151. A.G. 18:877.—A vigorous, attractive and amenable plant that bears abundant pitchers of rich coloring. The writer regards it as a natural hybrid from Borneo between *N. ampullaria* and *N. Rafflesiana*, as it blends parental characters of these.



2464. How the pitchers change their shape.

The earliest and best are mug-shaped ones; the topmost pitchers of old and tall plants are cylindrical. *N. Rafflesiana*, both from same plant. Adapted from B.M. 4285.

25. **Lawrenciàna,** Mast. (? *N. Phyllámphora* × *N. Hookeriàna*). Lvs. lanceolate, margins finely dentate-ciliate: pitchers 3–5 x 1½–2 in., ventricose below, cylindric above, pale green with heavy purple markings; wings expanded, fringed; peristome pale green and red-striped; lid oval. G.C. II. 14:40. I.H. 29:460.—One of Taplin's hybrids, and nearly resembling *N. Morganiana* which seems to have had the same parentage.

26. **Outramiàna,** Williams. One of Taplin's hybrids of doubtful parentage but probably *N. Sedenii* × *N. Hookeriana*, therefore closely like the following hybrid. F.M. 1879:384. F. 1880, p. 156.

27. **Williamsii,** Mast. (? *N. Sédenii* × *N. Hookeriàna*). Lvs. shortly petioled, lanceolate, margin slightly hairy: pitchers yellow-red with numerous and varying bright red spots. G.C. II. 14:40. Gn. 27:496.—Frequent in plant-houses.

28 **Chélsonii,** Veitch (*N. Hookeriàna* × *N. Domínii*). Lvs. petiolate, glabrous, oblong: pitchers 3–4 x 1½–2½ in., broadly ovate, yellowish green with purple spots; wings narrowing from below upward, fringed; peristome oblique, pale green and red-striped, lid green along middle, purple-spotted laterally. G.C. 1872:542 desc. Gn. 23:492. J.H.S. 21:237, 239. G.Z. 23:121.—A very commendable hybrid of Seden's raising. Var. *éxcellens* is the same as *N. edinensis* (No. 32).

29. **intermèdia,** Veitch (? *N. hirsùta* or *N. grácilis* × *N. Rafflesiàna*). Lvs. petiolate, lanceolate: pitchers 5–8 x 2–3 in., ovate, slightly ventricose below, green and abundantly small purple-spotted; wings conspicuous fringed; peristome cylindric, greatly elevated into a neck behind, pale green with purple stripes. G.C. II. 17:179. F. 1875, p. 257. Gn. 11, p. 429. G.Z. 21: 265. J.H.S. 21:237, 238.—A pretty, common, and easily grown hybrid.

30. **Rafflesiàna,** Jack (*N. Sanderiàna*, Burbidge). Figs. 2462, 2464. Lvs. long-petioled oval to lanceolate, like the st. white tomentose when young, at length glabrous: pitchers 3–7 x 2–4 in., dimorphic, lower urn-shaped, upper funnel-shaped, pale green with varied, purple spots and blotches; peristome uniform, much elevated into high neck behind; pitcher within with triangular glaucous conducting and lower shining detentive area. B.M. 4285. F.S. 3:213, 214; 16:1698; 22:2343. F. 1850:77; 1872, p. 221. G.C. 1872:1164. F.S.R. 2:113, desc.; 3:280. G.Z. 30:265.—Native from Malacca to Borneo and Sumatra, it was early brought to Eu., and is a parent of many hybrids. *N. nìgro-purpùrea*, Mast. (G.C. II. 18:429) is a dark purple form with almost white spots.

31. **Dicksoniàna,** Lindsay (*N. Rafflesiàna* × *N. Veìtchii*). Lvs. petiolate, deeply amplexicaul, blade elliptic-obovate, sparsely hairy beneath: pitchers 4–8 x 2–3 in., cylindric-ventricose, somewhat villous, pale green with abundant purple blotchings; peristome oblique, wide, pale green with purple stripes; lid oblong. G.C. III. 4:543, desc. Gt. 38, p. 466. Tr. Bot. Soc. Edin. 18:236. Gn.W. 6:25.—A beautiful hybrid that was raised by Lindsay in the Edinburgh Garden, but which is subject to lf.-spotting and scale.

32. **edinénsis,** Lindsay (*N. Rafflesiàna* × *N. Chélsonii*). Lvs. petiolate, lanceolate: pitchers 3–6 x 2–3 in., ovate, slightly ventricose, yellow-green with dark purple spots; wings expanded, widest below, fringed; peristome wide, subcylindric, slightly elevated into neck behind. A.F. 7:381.—Raised in the Edinburgh Garden by Lindsay, and a pretty hybrid when well grown, but rather difficult of treatment.

33. **Phyllámphora,** Willd. (*N. macrostàchya*, Blume. *N. fimbriàta*, Blume. *N. O'Brieniàna*, Rod. *Phyllámphora mirábilis*, Lour.). Fig. 2463. Lvs. petiolate, light green, herbaceous, glabrous, veins 6–10 pairs, margin dentate-ciliate: pitchers 3–6 x 1–1½ in., subcylindric, slightly inflated in lower half, pale green to red-green or red (*N. O'Brieniana*); wings narrow or as cords; peristome cylindric, transverse, green rarely red; lid orbicular. B.M. 8067. I.H. 37:116. Native from S. China to Borneo, Sumatra and N. Guinea.—It was first cult. nearly a century ago, and has been parent of several hybrids. It varies in shape and color in different localities.

34. **coccínea,** Mast. (*N. Hookeriàna* × *N. Phyllámphora*). This has probably the same parents as *N. Lawrenciana* and *N. Patersonii* and mainly differs in the more generally purple-red surface with yellow-green marblings and spots. G.C. II. 18:169. I.H. 41, p. 143.—It combines very fairly the good points of both parents in being an easily grown, abundantly pitchered and attractively colored type.

35. **Kennedyàna,** F. Muell. An Australian species very near to *N. Phyllamphora* that was grown from 1880 to 1890 and now is rare or lost to cult. G.C. II. 17:257.

36. **Ròwanæ,** F. M. Bailey. Plant stout, erect: pitchers large, dull crimson-green to crimson; peristome cylindric in front, expanded widely behind. G.C. III. 22:338, desc.. J.H.S. 22:192.—An Australian species, first found and illustrated by Mrs. Ellis Rowan, and which may yet be a well-known horticultural form.

37. **madagascariénsis,** Poir. The most outlying species of the genus and native to Madagascar. It forms low upright plants 2–3 ft. high, and bears deep crimson pitchers. It has been intro. repeatedly into French and English stovehouses, but seems to die off rather quickly. G.C. II. 16:685.

38. **bicalcaràta,** Hook. f. (*N. Dỳak*, Moore). Plant tall, stout, yellow-green: lvs. petiolate, large, with 8–14 veins: pitchers goblet-shaped, yellow to brownish or reddish green, rarely almost brick-red; wings conspicuous; peristome with 2 long sharp descending spines behind: fls. in long loose panicles. N. W. Borneo. G.C. II. 13:201. I.H. 28:408. Gn. 33, p. 29.—A remarkable species, but very difficult in cult.

39. **Veìtchii,** Hook. f. Fig. 2465. St. creeping, hairy, epiphytic: lvs. alternate, petiolate, decurrent, elliptic to obovate: pitchers 4–8 x 1½–3 in., yellow-green to reddish hairy; wings expanded and fringed or rudimentary; peristome pale green or red-green, widely expanded behind (Fig. 2465); lid yellow-green with strong basal keel within. B.M. 5080 (as *N. villosa*, in error). G.C.

1872:542, desc.; II. 16:781; 18:808 (as *N. sanguínea*, in error); III. 20:239, desc. F.M. 1877:265. I.H. 23:192. —A unique species from Borneo that has been a parent for many of the best hybrids.

40. **alàta,** Blanco. Plants terrestrial or epiphytic: st. trigonous: lvs. amplexicaul, petiolate, elliptic-lanceolate, nerves 3, rarely 4 pairs: pitchers somewhat dimorphic, cylindric-ventricose to cylindric, finely stellate-pubescent; wings rudimentary below, widening and fringed above; peristome oblique, slightly elevated into a neck behind; lid broadly cordate with internal basal keel. Fl. Filip. ed. 3:III 214; IV. 173.—As yet not intro. from the Philippine Isls., but of bright color and graceful shape; deserving therefore of attention.

41. **Ràjah,** Hook. f. Fig. 2462. St. upright, stout: lvs. large, thick, coriaceous: mature pitchers 5–9 x 3–5 in., red-purple or green-purple; wings widening from below upward, fringed; peristome widely expanded with undulate margin, deep crimson; lid large cordate. Tr. Linn. Soc. 22:421. G.C. II. 16:493. Gn. 22, p. 122. F. 1883:167. B.M. 8017.—A magnificent species from Kinabalu, Borneo, that is difficult under cult. Moore, of Glasnevin, has succeeded well by growing it in a "filmy-fern atmosphere."

42. **nóbilis,** Veitch (*N. sanguínea* × *N. máxima* var. *supérba*). Lvs. slightly stalked, thick, herbaceous, elliptic-oblong, peltate at apex: pitchers 6–9 x 1½–2 in., cylindric, brownish red with scattered purple blotches; wings expanded ciliate; peristome oblique crimson-purple, outer margin wavy; lid with shallow basal crest. G.C. III. 45:25.—A striking hybrid with richly mottled interior to the pitchers.

43. **Dyeriàna,** Macfarlane (*N. míxta* × *N. Dicksoniàna*). Lvs. petiolate amplexicaul, decurrent, oval to elliptic-obovate, apex often peltate: pitchers 5–12 x 2–3½ in., cylindric-ventricose, yellowish green with abundant purple spots and blotches; wings wide, long-ciliate; peristome widely expanded and elongated somewhat into a neck behind; lid with prominent external keel. G.C. III. 28:257; 38:325, desc.—A splendid hybrid that grows readily, and forms large pitchers. It was raised by Tivey and sent out by the Veitch firm in 1900.

44. **Wíttei,** Veitch (*N. stenophýlla* × *N. máxima*). Lvs. deeply amplexicaul, petiolate, with expanded winged base, elliptic-obovate with rounded or peltate apex: pitchers 3–7 x ½–1½ in., tubular with brown pubescent girdle below peristome, pale green with red or purple areolations; wings intermediate between those of parents; lid with basal median-keel within. J.H.S. 21:238.—Raised by M. Witte, curator of Leiden Garden, it is very nearly between the two parents.

45. **truncàta,** Macfarlane. Lvs. large, petiolate, lamina truncate at base and apex: pitchers large, urceolate, crimson; wing narrow or cord-like; peristome widely expanded, undulate without; lid small, keeled at base within. Bot. Contrib. Univ. Penn. 3:207, pl. 2.—A remarkable species collected by W. J. Hutchinson during 1907 in Mindanao, Philippine Isls.

46. **stenophýlla,** Mast. Lvs. petiolate, elliptic-lanceolate, lf.-veins 3: pitchers 3–5 x ½–1 in., tubular, slightly ventricose below, pale green with abundant purple spots and areoles; wings nerve-like below, slightly expanded in middle, fringed toward mouth; lid with internal basal keel. G.C. III. 8:240, desc.; 11:401.—A neat, graceful and richly colored species from Borneo, but hard to grow. It is now rare in cult., but its hybrid *N. Wittei* is fairly easily grown.

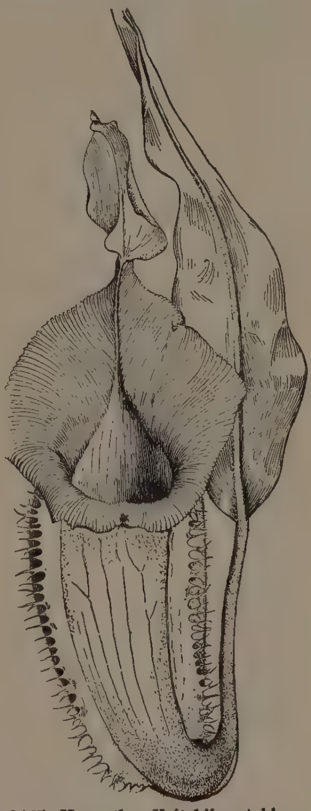
47. **máxima,** Reinw. (*N. celébica,* Hook. f. *N. Cùrtisii,* Mast. *N. fàllax,* G. Beck). Lvs. amplexicaul, petiolate, elliptic with brown ciliate margin: pitchers dimorphic to trimorphic, lower ventricose below, cylindric above; wings expanded, fringed; middle pitchers cylindric with narrow unfringed wings; upper funnel-shaped with wings reduced to cords; all pale green, heavily blotched or overlaid by purple areoles; peristome cylindric in front, expanded and undulate posteriorly, green-purple to dark purple; lid cordate with basal crest and subapical spur within. G.C. III. 2:689; 6:661. B.M. 7138. I.H. 35:59.—A richly colored species that is native to Celebes, Borneo, and N. Guinea, and that was intro. by Curtis from Borneo. It thrives well, flowers freely, and has been a parent of some striking hybrids.

48. **Tíveyi,** Mast. (*N. máxima* × *N. Vèitchii*). Lvs. amplexicaul, decurrent petiolate, elliptic-obovate, apex peltate: pitchers 3–10 x 1½–3 in., cylindric, yellow-green with many large irregular purple blotches; wings imperfect below, expanded and fringed above; peristome widely expanded and undulate laterally, elevated into a neck behind; lid inside with basal keel and subapical spur. G.C. III. 22:200, 201. G.M. 40:599. J.H.S. 21:238.—A large strong and cultivable hybrid that was raised by Tivey. It promises to become a favorite type.

49. **Balfouriàna,** Mast. (*N. míxta* × *N. Mastersiàna*). Pitchers 5–10 x 2–4 in., cylindric-ventricose, green with few large purple spots over surface or mainly toward peristome; wings large, fringed; peristome expanded, purple and green-striped; lid with subapical spur. G.C. III. 26:91.—A striking and fairly easily grown hybrid that was raised by Tivey, and which blends the parental characters of *N. Northiana, N. maxima* (*N. Curtisii*), *N. sanguinea* and *N. khasiana.*

50. **Lòwii,** Hook. f. Fig. 2462. A striking species from Kinabalu that bears large yellow-green leathery pitchers, shaped as in Fig. 2462. It has not been intro. into cult.

51. **Macfárlanei,** Hemsl. A Malayan species with oval or funnel-shaped pitchers that are green, with extensive deep claret areolations. The lid bears long hirsute bristles within.—Not yet in cult., but a promising species for hybridization.



2465. Nepenthes Veitchii, notable for its wide rim.

N. Allióttii=N. Northiana × N. maxima.—*N. atropurpùrea*=N. sanguinea × N. maxima var. superba.—*N. Boisiàna*=N. Tiveyi × N. Morganiæ.—*N. compácta*=N. Hookeriana × N. Phyllamphora.—*N. Còurtii*=N. (?) × N. Dominii. A hybrid of Court that is rare in cult. G. C. II. 16:845.—*N. Deslògei*=N. Tiveyi × N. mixta.—*N. excélsa*=N. Veitchii × N. sanguinea.—*N. Fournièri*=N. Northiana × N. mixta.—*N. J. M. MACFARLANE.

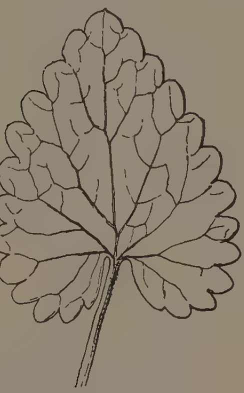
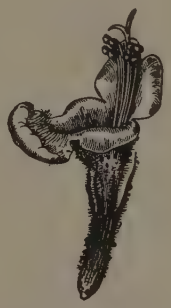
NÉPETA (Latin, perhaps from Nepete, an Etrurian city). *Labiàtæ.* This group includes catnip, ground ivy and some other hardy perennial herbs of the easiest culture.

Perennial or annual herbs, tall and erect, or dwarf and more or less trailing: lvs. dentate or incised, the floral ones like the rest or reduced to bracts: whorls of fls. crowded in a dense spike, or in a loose cyme, rarely few-fld. and axillary; fls. blue or white, seldom yellow; calyx 15-nerved; corolla somewhat 2-lipped; upper lip straight or erect; lower lip spreading, 3-lobed, with the large center lobe concave; perfect stamens 4, in pairs, the 2 shorter ones in front; ovary 4-parted. The genus is placed near Lopanthus and Dracocephalum, and is characterized as follows: calyx tubular, the mouth straight or oblique, 5-toothed; stamens usually parallel, ascending; anther-cells divergent or divaricate.—About 150 species, mostly in the northern hemisphere outside the Old World tropics.



2466. Leaf of catnip.



2467. Catnip.—Nepeta Cataria. (×3)

Catnip is a familiar weed near dwellings and barns. Cats are fond of it, and catnip tea is a pungent memory with those who have survived the era of homely simples. The seeds of catnip are still offered. Ground ivy (*N. hederacea*) also grows wild in America, and a form of it with variegated foliage is cultivated for edging flower-beds or covering banks and stones. It is hardy in light well-drained soils, but sometimes winter-kills in moist soils. It is also used in vases and baskets. *N. hederacea* is a perennial creeping plant of easy culture in any loose, rich, fairly moist soil in either shade or full sunlight, but to be luxuriant in the open it should have a moist rootage. It is a very rapid grower, and is therefore often troublesome when planted with other low-growing plants. It is very useful as a ground-covering in shrubbery borders and shady places generally, particularly where it can hang over curbs or edgings or where a good sward cannot be secured.

A. *Blossoms small, rather inconspicuous.*

B. *Color of fls. white or nearly so.*

Catària, Linn. CATNIP OR CATNEP. CATMINT. Figs. 2466, 2467. Perennial, densely downy, pale green: st. rather stout, tall and erect: lvs. heart-shaped, green above, whitish below, crenate, stalked: corolla nearly white, or pale purple, dark-dotted. Blooms from July–Nov. Eu., Orient.

BB. *Color of fls. blue.*

hederàcea, Trev. (*N. Glechòma,* Benth. *Glecòma hederàcea,* Linn.). GROUND IVY. GILL-OVER-THE-GROUND. FIELD BALM. Fig. 2468. Perennial, hairy: creeping sts. leafy, making a dense mat: lvs. roundish, more deeply notched at the base than catnip, and green on both sides, the floral ones like the others, not reduced to bracts as in the other kinds here described; lower petioles longer than the lvs.: whorls axillary, few-fld., blue. Nat. from Eu., Asia. C.L.A. 23:57. B.B. 3:87. G.W. 9, pp. 244, 245; 13, p. 558—Other old vernacular names are alehoof, cat's-foot, gill, gill-ale, gill-go-by-the-ground, hayhofe, haymaids, hove, tunhoof, creeping charlie, robin-run-away, gill-runover, crow-vituals, wild snake-root, hedge-maids. March–June.—The green-lvd. form is less cult. than var. **variegàta,** Hort. (*N. hederàcea,* Trev., var. *variegàta,* Hort.).

AA. *Blossoms larger, showy, blue.*

B. *Lvs. not notched at the base.*

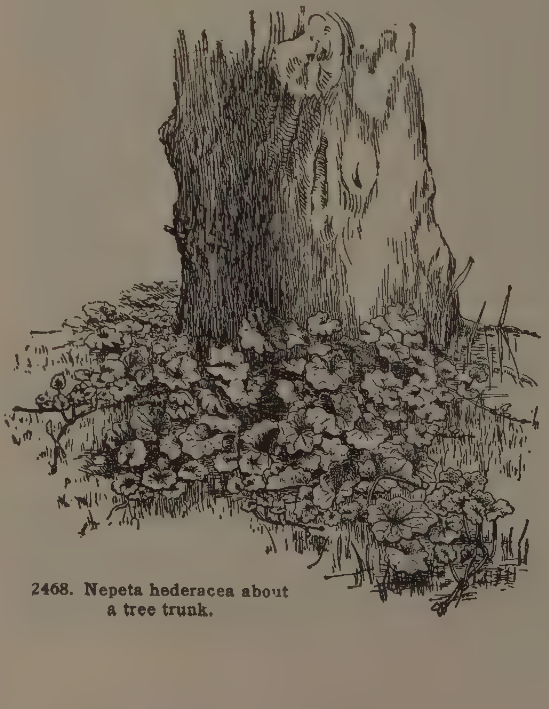
macrántha, Fisch. Erect plant, branching, nearly glabrous: lvs. short-stalked, ovate-lanceolate, green on both sides: cymes peduncled, few-fld.; fls. 1 in. long; bracts minute. Altai. B.M. 2185 (as *Dracocephalum sibiricum*).—Prop. by division of underground sts.

Wìlsonii, Duthie. Allied to *N. macrantha:* herbaceous perennial, 2–2½ ft. high: lvs. shortly stalked, the upper subsessile, ovate-oblong, 2½–3¼ in. long, obtuse, crenate: fls. in distant whorls, short-stalked; corolla violet, about 1 in. long, with a slender tube white at the base, curved and enlarged above. W. China.

BB. *Lvs. notched at base.*

C. *Fls. pedicelled.*

grandiflòra, Bieb. (*N. melissæfòlia,* Pers.). Height 20 in. or more: plant nearly glabrous, green: st. erect and branching: lvs. short-petioled, large, long, heart-shaped, crenate-margined: corolla with upper segm. awl-shaped, much shorter than the violet, hairy lower segm.; calyx-lobes long pointed; fls. beautiful blue. Known in gardens as *N. argéntea,* Hort., *N. grándis,* Hort., *N. incàna,* Hort., *N. teucrioìdes,* Hort. Summer. Caucasus.



2468. Nepeta hederacea about a tree trunk.

betonicæfòlia, C. A. Mey. Upper lvs. green on both sides, notched at base, and cordate: bracts a half shorter than the calyx: fls. pedicelled in dense heads: racemes simple, short; calyx elongate, villous, hardly dilated. Caucasus.

Veìtchii, Duthie. Perennial, herbaceous: whole plant covered with minute rather hispid hairs: st. 1–1½ ft. high: lvs. narrowly oblong, lanceolate, 1–2 in. long, acute, cordate at base, crenate-dentate, rugose; the lower stalked, the upper without petioles: fls. in distant whorls; corolla light blue, about 1½ in. long, with a long narrow deflexed tube. W. China. G.C. III. 40:334.—A recent intro. Handsome.

cc. *Fls. sessile.*

Mussìni, Spreng. Diffuse: branches many, ascending: lvs. green above, whitish below: racemes unbranched; bracts much shorter than the calyx: lvs. small, heart-shaped, blunt, deeply notched: corolla blue, darker spotted. Caucasus, Persia. R.H. 1891: 300. B.M. 923 (*N. longiflora*). Gn. 72, p. 563; 74, p. 413; 78, p. 518.

A. C. Hottes.†

NEPHÈLIUM (an ancient name transferred from the burdock, because of some similarity in the rough fruits). *Sapindàceæ.* Oriental tropical trees, some of them prized for their fr.; species more than 30. Four frs. prized in the Orient have been referred to this genus, the litchi, longan, rambutan and pulassan, the last one not having a general reputation. Recent botanists, however, separate these into the genera Euphoria, Litchi and Nephelium. The characters of separation are: **Euphoria.** Fr. tubercled with rugose, flattened, sometimes indistinct tubercles; aril free; embryo straight, radicle at the base of the seed: petals present; sepals imbricate: includes the longan or longyen (*E. Longana*, Lem. *Nephelium Longana*, Cambess. See *Euphoria*). **Litchi.** Fr. tubercled with angular prominent tubercles; aril free; embryo straight, radicle at the base of the seed: petals wanting; sepals valvate, small: includes the litchi (*Litchi chinensis*, Sonn. *Nephelium Litchi*, Cambess. See *Litchi*). **Nephelium.** Fr. echinate-muricate, sometimes smooth; aril adnate to the seed; embryo curved, the radicle near the apex of the seed: petals wanting, in some species present; sepals valvate, small.

The three species mentioned above may be distinguished by the lvs. as follows: The longan has usually 4 pairs (2–5) of lfts., coriaceous, strongly veined, acuminate but more or less obtuse at point, 2–4 in. or more long; the litchi has usually 3 pairs of lfts., coriaceous, indistinctly veined, glaucous beneath, obtusely acuminate, 2–5 in. long; the rambutan has usually 2–3 or more pairs of lfts., chartaceous, strongly veined, often obtuse, 3½–7 in. long; the midrib is somewhat raised above, impressed in the two preceding species. The longan is offered both in S. Fla. and S. Calif. It is said to have been intro. in Calif. probably 25 years ago; it is also reported that the litchi and *Alectryon excelsum* have been sold for the longan.

L. H. B.

The rambutan, pulassan and longan.

The rambutan (*Nephelium lappaceum*, Linn.) and the pulassan (*N. mutabile*, Blume) are commonly cultivated in the Malay archipelago, where they appear to be indigenous. The longan (*N. Longana* or *Euphoria Longana*), said by De Candolle to be a native of India, is considerably hardier than the first two, and is found as far north as southern China, where it is rather extensively grown.

The rambutan is seen in almost every garden about Singapore and Penang, and its fruit is one of the most delicious of the region. The tree, which grows to a height of 35 or 40 feet, is erect and stately in appearance, with compound leaves composed of five to seven pairs of oblong leaflets about 4 inches long. It is commonly stated that there are eight or ten varieties of the rambutan, but these appear to differ very little from one another, and are rarely propagated by grafting or layering. The fruits are produced in terminal clusters of not more than ten or twelve, and individually are the size of a small hen's egg, oval in form, and covered with soft fleshy spines ½ inch in length. The color is bright crimson, occasionally greenish or shaded with orange. The pericarp is thin and leathery; to eat the fruit the basal end is torn off, exposing the whitish, translucent juicy pulp or aril, which, with a slight pressure on the apical end of the fruit, slides into the mouth. The flavor is acidulous, somewhat suggesting the grape, and generally considered by Europeans very pleasant, though not equal to that of its relative, the litchi. An oblong flattened seed nearly 1 inch in length is inclosed by the aril.

The pulassan is often confused with the rambutan which it greatly resembles, but is distinguished by the shorter blunt spines and the aril separating more readily from the seed. The flavor is sweeter and generally preferred to that of the rambutan.

It is not known that either of these species has ever fruited in tropical America, their culture being limited, practically speaking, to southern Asia. They are usually grown from seed, but layering and grafting are often used to perpetuate choice seedlings. The gootee method, described under Litchi, is successful.

The longan, called by the French "œil de dragon," or dragon's eye, greatly resembles the litchi except in its smaller size and inferior flavor. It ripens later than the litchi and is very popular among the Chinese, quantities of the fruit being sold in Hong Kong and Canton during late summer. It has been introduced to the United States and planted in both Florida and California, where it fruits abundantly and appears to thrive, when grown in locations which are protected from severe frosts. The fruits, which are produced in large terminal clusters, are ½ inch in diameter, spherical, with a thin leathery pericarp and whitish, gelatinous pulp or aril inclosing a shiny brown seed the size of a bean. The flavor is generally considered rather insipid. As a stock on which to bud the more tender litchi the longan may have considerable value, although its growth is rather slow.

F. W. Popenoe.

NEPHRÒDIUM. A name used by some botanists, especially in England, for species of Dryopteris, which see.

NEPHRÓLEPIS (Greek, *kidney scale*, alluding to the shape of the indusia). *Polypodiàceæ.* Sword Fern. A group of tropical and subtropical ferns.

Leaves pinnately divided; pinnæ articulated or jointed, the veins free-forking, the sori on upper forks of the veins and with kidney-shaped indusia which are attached inwardly.—Four species are in more or less common cult. Of these, *N. exaltata* is the most important as it is best adapted to general cult. and also it has given rise to a large number of important horticultural varieties. It is, perhaps, safe to say that this species and its varieties constitute the most important single species of fern in cult. for house purposes. The three other species have each given rise to a few varieties but none of them is well adapted to house conditions, so that they are mainly confined to greenhouses.

In the index that follows most of the names belong to varieties of *N. exaltata*, or more accurately to varieties of *N. exaltata* var. *bostoniensis*, but in the trade they are counted as species and are given specific names. Technically *N. elegantissima* should have a much longer name if its true relationship were to be indicated. To illustrate, *elegantissima* is a variety of *Piersonii*, which is a variety of *bostoniensis* and this a variety of the original species, *N. exaltata*. Thus its scientific name is properly *N. exaltata* var. *bostoniensis* var. *Piersonii* var. *elegantissima*. In the present treatment the trade names are used, but in connection with the descriptions the origin of each form is given when known. The index includes all the names that have been met, although no information has been available regarding some of them. Very few of the English varieties are grown at all in the U. S. English varieties are indicated thus: (E).

Methods of cultivation.

In general, nephrolepis must be propagated entirely by runners. Few if any spores are produced by the varieties. As a plant comes to be a year or so old, the leaves develop the usual fruit-dots or sori, but when examined under the microscope it appears that these consist of abortive sporangia or spore-cases and contain no spores. It is probable that spores are developed occasionally, but so rarely that this method can not be used in propagating new plants commercially. A vigorous plant will, however, produce numerous runners which spread in all directions and take root, starting new plants in this way. It is customary to maintain a number of stock plants planted out in benches from which new runners can be plucked as needed. This also gives a good opportunity for the production of new varieties.

New varieties of commercial value do not appear very frequently in the commoner varieties. Most of the present standard varieties have been propagated from single original plants, although there are cases of a certain type of variation occurring simultaneously with different growers, one of whom might count it worthy of introduction while another would disregard it.

All growers unite in acknowledging the original Boston form as the best grower of all and it appears also that there is a greater demand for this form than for any other. The next most popular form is probably *N. Scottii*, with *N. elegantissima* the third. Teddy Jr., and the large frilled forms, *N. Harrisii* and *N. Rooseveltii*, are also grown by most dealers.

There are two main methods of growing nephrolepis for the market, the pot method and the bench method. In the former, stock plants are grown, planted out in the benches, from which new runners are picked from time to time. These are then potted in 2½-inch pots and transferred to larger pots as becomes necessary. In the bench method, the runners are planted out in the benches and grown to good size when they are put into pots, perhaps 6 inches, and kept till rooted, and then sold.

It would appear that the pot method should produce plants which would be better suited to thrive in house conditions, owing to a better establishment of the roots. Then, too, the leaf-growth should also be better, as the transfer from the bench to the full-sized pot would tend to stop vigorous growth for a while.

Some growers market almost their entire product in the form of the bench runners. This of course is entirely wholesale trade. Such runners bring from 4 to 5 cents in thousand lots. When sold in pots, the price depends on the size of the pot. The various kinds bring in general the same prices. Well-grown plants in 6-inch pots sell wholesale at 50 cents apiece.

These ferns are grown from Maine to Florida. In general, a supply from near at hand is better than one coming from a distance. A lot of Boston runners (5,000) obtained from Florida and grown in Massachusetts were recently seen which were most unsatisfactory. At the end of a month there had been scarcely any growth, while for similar runners obtained nearby three weeks should see them well established and ready for sale. One large grower found another danger in Florida importations in the Florida moth, which nearly cleaned out their supply of ferns before they discovered that sprays of hellebore or pyrethrum destroyed it.

A. *Rootstocks with small tubers.*

1. **cordifòlia,** Presl (*N. tuberòsa*, Hook. *N. cordàta*, Hort.). Lvs. numerous, tufted, with stiff petioles, 15–30 in. long, 1½–2 in. wide, with close often overlapping pinnæ, these usually blunt and crenulate. Mex., Japan, and New Zeal.—A rather slow grower. It reproduces by runners but less freely than *N. exaltata*. Commonly known in the trade as *N. cordata* and under this name has several varieties as vars. *compácta*, *gigantèa*, *tessellàta* and *variegàta*. Var. **plumòsa,** common in the trade as *N. tuberosa plumosa*, is a beautiful form with glossy dark lvs. which have the pinnæ once-pinnate in the outer half or two-thirds. Var. **Dúffii** is a remarkable wild variety with the pinnæ reduced to one or two rounded segms. Var. **pectinàta** lacks the tubers and has narrower, more spreading lvs. Probably a distinct species.

AA. *Rootstocks without tubers.*

B. *Sori on special narrow segms. of the fertile lvs.*

2. **acuminàta,** Kuhn (*N. davallioìdes*, Kunze). Lvs. drooping, 2–3 ft. long, 1 ft. or more wide, the lower pinnæ incised crenate, the upper pinnæ narrower, with deeper lobes, each with a single sorus at the apex. Java. —A cult. variety with forked pinnæ is grown, advertised as *N. furcans* and *N. furcans multiceps*.

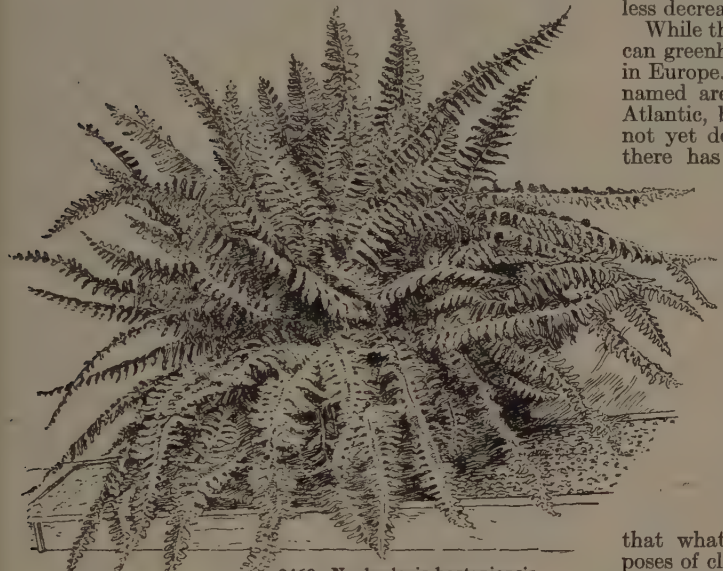
BB. *Sori along margins of ordinary divisions of lvs.*

3. **biserràta,** Schott (*N. acùta*, Presl. *N. Baùsei*, Hort.). Lvs. few, 30–55 in. long, 8–12 wide, drooping, the pinnæ often distant, elongate, narrow, with entire or crenulate margins, rounded in the lower half of the base, auricled in upper half, leathery. Pan-tropic. *N. ruféscens* is a scaly form. Var. **supérba,** usually ascribed to *N. exaltata*, may be a variety of *N. bisserrata*. It is characterized by a crested many-forked apex, and has laciniate-margined pinnæ. Var. **fúrcans** has the pinnæ once or more forked.

4. **exaltàta,** Schott. SWORD-FERN. Lvs. rather rigid and erect, 2–5 ft. long, 3–6 in. wide, oblong, tapering toward the point, the pinnæ rather close, acute, entire or crenulate, the upper side auricled. Fla. to Brazil, Hong-Kong and E. Afr.—This description applies only to the wild species. It is impossible to give a description which will include all the forms which have been derived from this species. Each distinct form needs separate treatment. The varieties of *N. exaltata* have practically all arisen in the last twenty years, since the early nineties. At that time this species was grown to some extent by florists as a house-plant but was not more common than many flowering species. It happened, however, that in a lot of this species of about 200 plants, shipped by Robt. Craig & Co., of Philadelphia, to F. C. Becker of Cambridge, Mass., there was discovered one plant which differed from the ordinary *exaltata* in being more graceful, slightly broader, and a quicker grower. The purchaser identified this plant as the species *acuminata* or, as it was then called, *daval-*

lioides, and proceeded to raise and sell it by the scores of thousands. Later, when a specimen of the fern came into the hands of G. W. Oliver, the latter raised the question of its identification and declared that it was not *davallioides* but *exaltata*, though not the typical form. For some time thereafter Messrs. Becker and Oliver exchanged opinions in the "Florists' Exchange," until Oliver's determination was accepted. The nomenclature commission of The Society of American Florists did not feel competent to give a name to the new variety so it was sent to Kew where it was suggested that the neighborhood of its discovery might well be honored by calling it *bostoniensis*. This name was given in 1896. The fern had been on the market for a year or more previously.

For nearly ten years the Boston fern held undisputed sway. The original species-form was superseded owing to its less graceful stiffer habit. Then in 1903 there appeared a new type of variation in the greenhouses of F. R. Pierson, of Tarrytown, N. Y.



2469. Nephrolepis bostoniensis. (Spread, 7 ft.)

In this new form, the Boston fern departed from its once-pinnate type to give rise to a twice-pinnate form which was introduced as *Piersonii*. But this fern was not consistently once or twice pinnate but both, and after a time it appeared that this unstable condition was not very satisfactory. It was found possible to obtain by careful selection a more fixed type of the twice-pinnate form and when this was introduced it was given the name of *elegantissima*. This was followed by other forms showing the two-pinnate character, and later forms appeared three and even four times divided.

A year or two later, in Brooklyn, another type of variation developed from the Boston fern. This was the dwarf type, with which came some other differences, but with the once-pinnate character retained as in the parent form. John Scott brought out the first of these dwarf types but there are now a half-dozen different dwarf once-pinnate forms.

About this time Harris, of Philadelphia, discovered and introduced a once-pinnate type with beautifully waved pinnæ and called it *Harrisii*. This has since been followed by wavy dwarfs, wavy twice-pinnate forms. Pierson again came to the front with a new type of variation in which the leaves are irregularly curled and twisted so that the resulting leaf becomes a dense thick mass of divided pinnæ, the *superbissima* and *muscosa* forms.

At the present time, with these four main types of variation to start with, and with others, such as thickness of petiole, rapidity of growth, stability of form, and the like, there have come almost all possible combinations and mixtures of these main types so that within certain limits almost anything is possible. Every grower who produces any quantity of these forms is having new types develop in his beds. Many of these are of no commercial value. A few new ones are introduced each year but some which at first appear good prove to have serious defects after testing for a year or two.

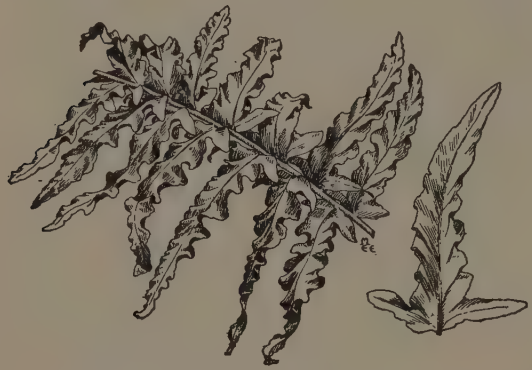
It is an interesting fact that, after ten years of new forms, the old Boston fern still holds its own and sells more readily and in larger amounts than any new form. It appears that with the later variations there has come also less adaptability to house conditions and more or less decrease in the vigor of growth.

While these variations have been appearing in American greenhouses, the same thing has been taking place in Europe. In some cases the new forms produced and named are practically identical on both sides of the Atlantic, but each region has produced distinct types not yet developed by the other. Generally speaking, there has been almost no importation into North America of the new European forms. For this reason little attention is here paid to European forms in this treatment. Not much is known about them by our growers and collectors.

The classification of the forms of *N. exaltata* is a difficult problem on many accounts. In the first place, owing to unscientific horticultural methods of description and publication of names, it is practically impossible to get accurate printed records of the different forms. Some growers have the custom of merely placing a new form on the market without so much as a catalogue or periodical advertisement. At best it is a case of advertising descriptions for the purpose of sale so that what is stated can not be accepted for the purposes of close and accurate description. In the second place, the types of the variations themselves are often of such a character that it is hard to draw up good differential descriptions. Two varieties may vary not at all in the cutting of the leaves but very markedly in the important characters of cultural needs and response. Again, it is usually the case that earlier varieties become superseded by later ones of greater commercial possibilities. The grower then has no sentiment about the original forms but discards them, so that it is practically impossible now to get plants of some of the early stem-varieties from which nearly all of the later have sprung. Added to these difficulties is often indifference on the part of growers to the need of accuracy in naming forms. A single form may be sold by different florists under totally different names.

The descriptions given below of the various forms have been drawn up as far as possible from authentic material obtained from the original producers themselves. Numerous visits have been made to growers in the neighborhood of New York, Boston, and Philadelphia. A collection of living plants has been started at the Brooklyn Botanic Garden, the main object of which is to gather authentic plants of the varieties. It should be noted here that, however careless as to the accuracy of descriptions and names the various growers have been, they have been exceedingly courteous in affording opportunities for study and in giving such information as they possessed.

The varieties chosen for description are those found to be in actual cultivation for the trade in the United States, together with some formerly in the trade but important because the modern varieties have sprung from them. Whenever possible, other varieties have been given incidental description by comparison with the more important forms. In some cases it has not been possible to settle the claims advanced for two or more similar varieties and in such cases the varieties have been given coördinate treatment with a single description. English varieties about which little information has been available have been mentioned where possible in connection with similar American forms.



2470. Nephrolepis Harrisii. (×⅛; pinna ×½)

In the key below dimensions given are for well-grown plants in 6-inch pots. In the smaller varieties, these dimensions are maximum, but some of the larger types may develop leaves as long as 6 feet.

A. *Exaltata forms with lvs. 1-pinnate or sometimes pinnate-pinnatifid.*

B. *Length of lvs. 2½–3 ft.*

C. *Pinnæ plane, the margins straight.*

5. **bostoniénsis.** Fig. 2469. Intro. by F. C. Becker, 1895. Free-growing, the lvs. dark green, spreading or hanging according to the light, the petioles rather succulent, the pinnæ linear-lanceolate, acute, 3–4 in. long, ½–¾ in. wide, entire or crenulate, plane or slightly undulate, herbaceous, less stiff than type form, with more graceful and broader pinnæ. The standard variety and best of all for general purposes. Good as a pot-plant (6 in. or more) or in baskets, on palm trunks or in the rockery. It may be planted out in the southern states.

CC. *Pinnæ wavy.*

6. **Hárrisii.** Fig. 2470. Wm. K. Harris, from *bostoniensis.* **Wm. K. Harris,** Wm. K. Harris, from *Harrisii* is merely *Harrisii* selected for the greater waviness of the pinnæ. See *Rooseveltii.*

7. **Roòseveltii,** Amer. Rose and Plant Co., from *bostoniensis.* Like *bostoniensis,* except for the pinnæ which are beautifully waved and usually auriculate. *Rooseveltii* is exactly like the Harris forms as to the undulation of the pinnæ, but is not quite so large a form and can consequently be better grown in 6-inch pots. Both make beautiful plants when well grown. *Harrisii* and *Rooseveltii* probably represent separate sports of two distinct types of Boston fern which exist in the trade, one taller than the other.

8. **New York,** Giatras, 1913, from *Giatrasii.* Somewhat smaller than *bostoniensis,* the lvs. slender, narrow, the pinnæ somewhat undulate, 2–3 in. long, often blunt, the petiole slender, wiry. Good when well grown but rather slow. Like *Giatrasii* but larger.

BB. *Length of lvs. 15–24 in.*

C. *All the pinnæ entire, not pinnatifid.*

D. *Pinnæ not wavy or twisted.*

9. **Scóttii,** Jno. Scott, from *bostoniensis.* Lvs. spreading, recurved, the pinnæ close, revolute and recurved, the petioles stoutish, rather succulent, strong. This is the commonest of the dwarf varieties. When well grown, it forms a compact dense cluster of lvs. which have good lasting qualities. It is somewhat subject to white scale, and is slower than Teddy Jr.

10. **falcàta,** Wagner, from *Scottii.* Like *Scottii,* except that ends of pinnæ are 1- or 2-forked.

11. **Giatràsii,** Giatras, 1909, from *bostoniensis.* About the same size as *Scottii,* perhaps a little smaller, but different in having more flexible lvs., wiry petioles and midribs, nearly plane pinnæ. Well-grown plants perhaps more graceful than *Scottii* but slower-growing and therefore not so much used.

12. **Dwarf Boston,** F. R. Pierson, from *elegantissima compacta.* A little taller and more free-growing than *Scottii,* lvs. straighter, the pinnæ nearly plane.

DD. *Pinnæ wavy or twisted.*

13. **Teddy Jr.,** Amer. Rose and Plant Co., from *Rooseveltii.* Free-growing, dark green, with wavy pinnæ as in *Harrisii* or *Rooseveltii.* The pinnæ are broader than those of *Scottii,* the color is darker, and the plants quicker-growing. Replacing *Scottii* to some extent.

14. **Wágneri,** Wagner, from *Scottii.* A dwarf sport of *Scottii* with the pinnæ very close and somewhat curved. Resembles *viridissima,* but more regular.

15. **viridíssima,** Pierson, from *superbissima.* Lvs. dark green, rigid, erect, with twisted, closely imbricated pinnæ. Inherits the irregularity of *superbissima* and represents a 1-pinnate reversion. Found to be too slow-growing and too stiff to be valuable for trade.

CC. *All or some of the pinnæ deeply lobed or pinnatifid.*

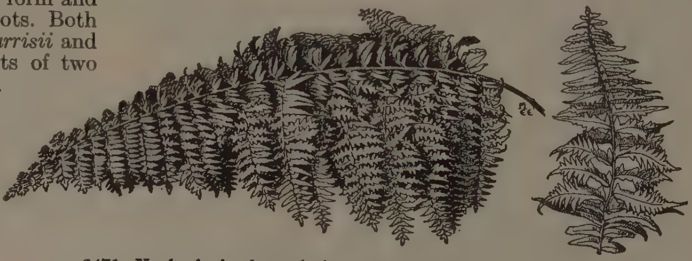
16. **Wanamaker Boston,** Craig, 1915, from *Scholzelii.* Lvs. rather narrow, erect and spreading, the pinnæ wavy, sometimes deeply lobed or pinnatifid in the outer halves, auriculate or with a single separate pinnule at the bases, often bent forward or backward. (This form represents the selection and prop. of the once-pinnate type of lf. often found on *Scholzelii.*)

AA. *Exaltata forms with lvs. 2-pinnate or 2-pinnate-pinnatifid.*

B. *Length of lvs. 2 ft. or more.*

17. **Pièrsonii,** F. R. Pierson, 1902, from *bostoniensis.* The first of the 2-pinnate forms and now discarded. Tall-growing, with the habit of *N. bostoniensis,* the lvs. unevenly divided, some 1-pinnate, some partly once- and partly twice-pinnate, and some entirely 2-pinnate. Important, because nearly all the later 2-pinnate types have come from it, but not itself desirable.

18. **Bàrrowsii,** Barrows, 1905, from *Piersonii.* Much like *Piersonii,* but somewhat differently divided. Another form of this type was called "Anna Foster." From this have come *Whitmanii* and *Magnifica.*



2471. Nephrolepis elegantissima compacta. (×⅛; pinna ×½)

BB. *Length of lvs. about 18 in.*

19. **elegantíssima,** F. R. Pierson, 1904, from *Piersonii.* Lvs. 18–20 in. long, 6–8 in. broad, the pinnæ 3–4 in. long, 1½–2 in. broad, almost completely divided into elongate, acuminate pinnulæ, these 1 in. long, ½in. broad, entire or deeply pinnatifid into linear segms. The most commonly grown of the 2–3-pinnate varieties. It succeeds because of a strong petiole and firm lf.-blade. The lvs. are often thick and dense, due to the broad overlapping pinnæ. A well-grown plant shows a very thick mass of lvs. *Elegantissima* "improved" is the stock grown at present and represents a selected type of *elegantissima* which shows less reversion than the original form. However, when not carefully grown, it will now show strong reversion to the once-pinnate Boston type.

20. **Whítmanii,** Barrows, from *Barrowsii.* In general, similar to *elegantissima* but the lvs. are more open, and the segms. smaller, less elongate than those of the Pierson form. *Whitmanii* "improved" is similar but shows less reversion. The differences in lvs. result in a less dense habit of growth. Reversion is uncommon under good conditions.

21. **todeoìdes,** Rochford (English). Like *elegantissima* but with even more elongate pinnulæ.

22. **robústa,** Craig, 1912, from *elegantissima.* Lvs. 2–2¼ ft. long, 10–12 in. wide, erect, firm, 1–2-pinnate, the pinnæ 4–6 in. long, 1½–2 in. broad when 2-pinnate, lobed at the base, narrower when not divided, the pinnulæ full, entire or crenulate. For the first year or so after its intro. this form showed little reversion but more recently it has begun to throw 1-pinnate lvs. It is a larger more open form than *elegantissima* and consequently more hardy. From *Piersonii* it differs in being broader-lvd. and more erect.

BBB. *Length of lvs. about 15 in. or less.*

23. **Schólzelii,** Scholzel, 1908, from *Scottii.* Lvs. 15 in. long, 4–5 in. broad, erect, simply 2-pinnate, the pinnæ somewhat recurved as in *Scottii,* often revolute, the pinnulæ large, ¼–½ in. long, entire or crenulate. Under the name *Scholzelii,* there is also sold a 3-pinnate form which arose in 1909 at Scholzel's place but which has never been given a separate name. Some of these 3-pinnate plants are erect, some have spreading lvs. Both belong in the next section with the 3-pinnate.

2472. Nephrolepis magnifica. (×⅓)

24. **M. P. Mills,** Harris, from *Scottii.* A twice-pinnate form with small distant segms., characterized by extreme hardiness and by very frequent reversion to the 1-pinnate type. The reverted plants do not appear to be ordinary *Scottii,* but have straight pinnæ and a more open growth. Both are slow.

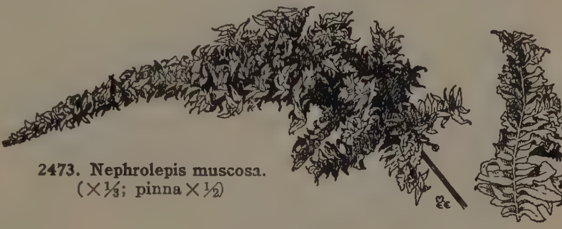
25. **elegantíssima compácta,** Fig. 2471, F. R. Pierson, 1909, from *Piersonii.* Lvs. about 12 in. long, erect, dense, numerous. In cutting like *elegantissima* except that it is often more divided and may be 3-pinnate.

26. **Whítmanii compácta,** Barrows, from *Whitmanii.* Lvs. 15–18 in. long, very full, nearly 3-pinnate. A beautiful form, the lvs. posssibly a little soft.

27. **Elmsfórdii.** Lvs. 12 in. long, 2–3-pinnate, with wiry petioles and a spreading habit. A pretty little form but not well known.

AAA. *Exaltata forms with lvs. regularly 3-pinnate or finer.*

28. **magnífica,** Fig. 2472, Barrows, from *Whitmanii.* Lvs. erect, 15 in. long, 4–5 in. broad, 3-pinnate with small ovate segms., ⅛–¼ in. long. A free grower of open habit, rather light green. More like the forms of the preceding section.



2473. Nephrolepis muscosa. (×⅛; pinna ×½)

29. **Smíthii,** J. C. Clark, from *Amerpohlii.* LACE-FERN. Lvs. 3-pinnate, 8–12 in. long, 6–8 in. broad, divided into very small, close segms. $\frac{1}{16}$in. long. The pinnæ are crowded so that the lvs. become very dense and are thus liable to injury by careless watering. There are a number of named varieties of the same general type but differing in growth characteristics. *Smithii* seems to be the most generally used. Others are as follows: **Amerpòhlii,** Amerpohl; **gracíllima,** *Barrowsii,* from *magnifica;* **Clárkii,** Smith, from *Smithii,* **Mílleri,** Miller; **Neùbertii** (German); **Róchfordii** (English); **Cràigii,** Craig, from *Smithii,* is 4-pinnate, with linear segms., but too soft to be of commercial value.

30. **superbíssima,** Pierson, 1908, from *elegantissima.* Lvs. mainly spreading, the pinnæ closely imbricated and irregularly twisted, firm, dark green, long-pointed, 10–15 in. long, 3–5 in. broad. A very interesting type, though not widely grown owing to its oddity and slowness. A single lf. may be very firm and dense. Throws buds with 1-pinnate lvs. frequently and these selected and grown constitute the var. *viridissima.*

31. **muscòsa,** Fig. 2473, Pierson, 1911, from *superbissima.* Practically dwarf *superbissima,* but makes more symmetrical plants and shows fewer reverting lvs. Lvs. 6–8 in. long, 4–5 in. broad, spreading, very firm and dense with the pinnæ and segms. closely imbricated. Like *superbissima* it is not widely grown. It is slow, and is also liable to injury from water, the lower pinnæ of the lvs. falling off.

32. **lycopodioìdes,** Rochford. Finely divided, irregularly twisted. Apparently like preceding but more finely cut. Probably not yet grown in the U. S.

Additional distinct types not commonly grown in Amer. and which are probably not derived from *exaltata* are:

33. **supérba,** May. Lvs. 20–25 in. long, 4–5 in. broad, the pinnæ deeply laciniately lobed, with the apices forked and crested, more or less recurved. A single lf. simulates well an ostrich plume.

34. **canaliculàta,** May. Has involute lvs. with the tips of the pinnæ laciniate and crested.

35. **Wíttboldii,** (F.R. 5:247) is described as having lvs. 3 times as broad as the typical *bostoniensis.*

Other forms which do not appear to be in the American trade to any extent are: *N. Bátchelori, crispàto-congésta* (E), *Dreỳeri, edmontoniénse* (E), *Faùlkneri* (E), *Fósteri* (E), *grándiceps* (E), *Héstonii* (E), *Márshallii, Márshallii compácta, Màyi* (E), *ornàta* (E), *phillipinénsis, recúrva* (E), *rugòsa* (E), *serrulàta, spléndens* E), *tripinnatífida, washingtoniénsis, Wéstonii* (E), *Wiedei, Wíllmotæ.*

R. C. BENEDICT.

NEPHTHỲTIS (name borrowed from Egyptian mythology; Nephthys, mother of Amibis, wife of Typhon). *Aràceæ.* Tropical African creepers, two of which are cultivated in hothouses for their variegated foliage.

Leaves more or less halberd-shaped or arrow-shaped, with scarcely any sheath on the petiole: infl. terminal; spathe concave-expanded; ovary 1-celled; ovule solitary, pendulous.—About half a dozen species.

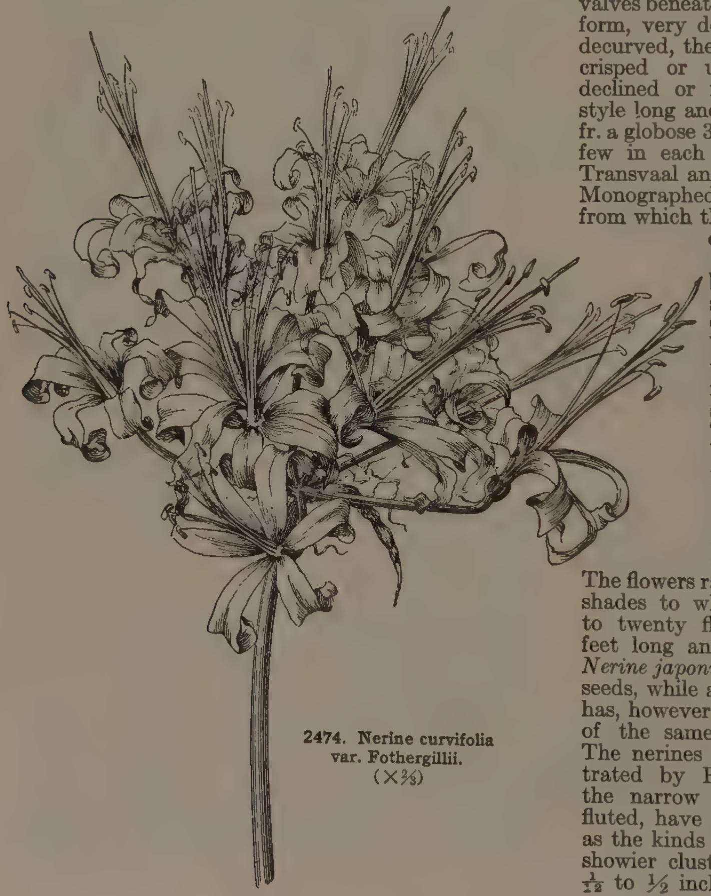
picturàta, N. E. Br. The white markings form a pattern resembling the tips of fern fronds laid between the nerves, with their points all directed toward the base of the midrib: plant stemless, spreading by runners: petioles 10–12 in. long; blade 6–12 in. long, 5–9 in. broad. Congo. Var. **angustàta,** N. E. Br., has smaller and narrower lvs. Figured in catalogues of U. S. Nurseries, 1895.

triphýlla, Hort. "A pretty stove creeper with dark green thrice-divided lvs. marked with greenish white in the exact shape of the lf."

Afzèlii, Schott (*N. libèrica,* N. E. Br.). Lvs. glabrous, the petiole 7–20 in. long, 1–2 in. thick, the blade sagittate, the portion in front of petiole-insertion up to 10 in. long, the basal lobes up to 6 in. long: spathe green, 2–2½ in. long. W. Trop. Afr. George V. Nash.†

NEPTÙNIA (*Neptune,* god of the sea: some of the species are aquatic). *Leguminòsæ.* Perennial herbs, or subshrubs, often floating, one of which is an aquarium plant.

Unarmed, prostrate or diffuse, the branches usually flattened or triquetrous: lvs. bipinnate, sometimes sensitive, the lfts. small: fls. not papilionaceous, perfect or polygamous, in spikes or heads on axillary peduncles; calyx 5-lobed; petals 5, distinct or somewhat cohering; stamens 10 or 5, exserted: pod oblong, oblique, 2-valved, somewhat septate between the ovate compressed seeds.—Species perhaps a dozen, widely spread in the tropics; a few of them are in the extreme southern U. S. and are plants of moist or even dry soil.



2474. Nerine curvifolia var. Fothergillii. (×⅔)

plèna, Benth. (*Mimòsa plèna,* Linn. *Desmánthus plènus,* Willd.). Natant, with prostrate sts., foliage sensitive and much like that of the common sensitive plant, *Mimosa pudica:* the fls. are so odd that one at first sight would not imagine that they belong to the legume family. They are small and collected in an ovoid head, 1½ x 1 in. and borne singly on stalks 6 in. long. These heads or spikes are drooping and have numerous stamens. The singular feature of these fls. is a mass of yellow petalage composed of 6 or more tiers of reflexed narrowly lanceolate bodies, which are really transformed and sterile stamens. The plant floats on pools and has grooved sts., the part under water being white, spongy and full of air-cells. Lvs. alternate and far apart; lfts. many, crowded, linear, obtuse. It is of difficult cult. and can probably not be secured in the trade at present. It grows in the E. Indies and S. Amer., and Mex. and elsewhere. B.M. 4695. B.R. 32:3. L. H. B.

NERÌNE (a nereid of Greek mythology). *Amaryllidàceæ.* Handsome autumn-flowering bulbs from South Africa.

Bulb tunicated, mostly without a neck: lvs. appearing after the fls. or with them, usually strap-shaped: fls. in shades of red and pink (varying to white), in few- or many-fld. umbels on a slender or robust scape; spathe-valves beneath the umbel 2, lanceolate; perianth funnelform, very deeply cut or divided, erect or somewhat decurved, the 6 segms. equal, narrow and more or less crisped or undulate; stamens 6, usually unequal, declined or nearly erect, bearing versatile anthers; style long and slender, straight or somewhat declined: fr. a globose 3-lobed and 3-valved caps., with seeds 1 or few in each cell.—Species 15–18, in Afr. from the Transvaal and Kalahari south to Cape of Good Hope. Monographed by Baker, Flora Capensis, vi (1896–7), from which the following descriptive account is mostly drawn.

Nerine is a remarkable genus of tender bulbous plants, of which the commonest species is *N. sarniensis,* long known as the Guernsey lily from the island where these bulbs are grown to perfection. The winter is their growing season instead of flowering time. They belong to the very small class of autumn-blooming bulbs. The common kinds flower from September to November without any foliage, and the leaves are developed all winter. About May the leaves die down and the bulbs rest from May to August. The leaves appear after the flowers in two or three species, but with the flowers in the others. The flowers range from scarlet through salmon and pink shades to white, and are borne in umbels of four to twenty flowers, on scapes varying from 1 to 3 feet long and averaging 1½ feet. A trade name is *Nerine japonica,* which is really a Lycoris; it has black seeds, while all the true nerines have green seeds. It has, however, the autumn-blooming habit and flowers of the same general appearance as the true nerines. The nerines have two distinct types of beauty, illustrated by Figs. 2474 and 2475. The kinds with the narrow perianth-segments, which are crisped or fluted, have a spidery look and are not so popular as the kinds with broad, flat segments, which make a showier cluster of flowers. The segments vary from $\frac{1}{12}$ to ½ inch in width. The showiest kinds are hybrids or varieties of *N. sarniensis* and *N. curvifolia*, the former species being the most prolific of varieties. In these two species the strong vertical lines of the erect long-protruded stamens make a striking feature. The flowers of the other species have more of a drooping tendency and the stamens are shorter and declinate, as in Fig. 2475. *N. pudica* is perhaps the choicest white-flowered kind. Nerines have bulbs 1 to 2 inches or less in diameter, and about six leaves, varying from 8 to 18 inches in length and 4 to 9 lines in width. Among the uncultivated kinds are some with short stout scapes and others with appendages at the base of the filaments. Nerine is closely related to Brunsvigia, being separated technically on the character of the capsule which is globose and obtusely angled in Nerine as distinguished from turbinate and acutely angled in the other. This distinction, however, seems not always to hold clearly. To the gardener, the differences are largely in relative size, Brunsvigia having larger bulbs, more numerous mostly larger flowers and commonly broader leaves.

The nerines are treated mostly as greenhouse plants. When well established in pots, they bloom year after year. In winter, the foliage is grown, and in spring water is gradually withheld until the bulbs are well ripened, when they remain dormant until August. John Robertson, in "Florists' Review" 1:675, gives advice as follows: the secret of success with nerines is to secure the fullest possible development of the bulbs. This refers to their winter treatment. They enjoy abundance of water at the root and overhead, with occasional applications of liquid manure. This treatment should never cease until the leaves turn yellow, which is a sign that the plants are finishing their growth. Then diminish the water-supply gradually, lay the pots on their sides where they are not likely to get wet, and in full sunlight, so that the bulbs may ripen thoroughly. The plants should not have their roots disturbed, nor do they require much root room: they grow and flower best when hard pot-bound. Three bulbs planted in good fibrous loam with a little sand may remain in a 5-inch pot for five or six years, or even longer, as the offsets can be rubbed off and separately potted while the parent bulbs go on increasing in size. Each year as the flower-scape appears pick off about an inch of the surface soil with a sharp-pointed stick, and give the ball of roots a good soaking and a slight top-dressing.

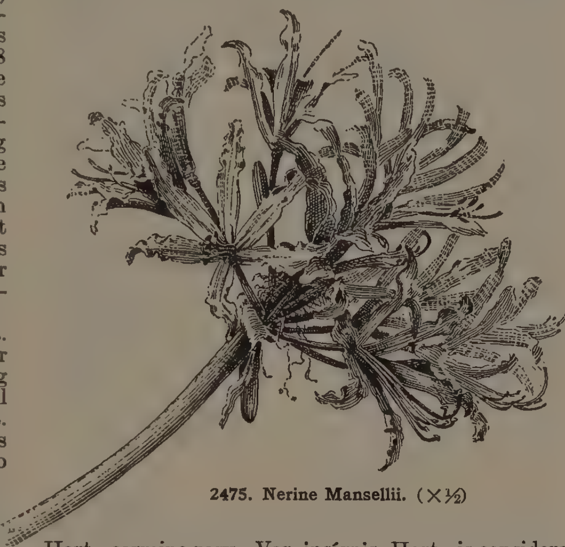
A. *Stamens and style nearly erect.*

B. *Lvs. green, suberect.*

1. **sarniénsis,** Herb. GUERNSEY LILY. Bulb ovoid, to 2 in. diam., the coverings pale brown: lvs. about 6, bright green, developed after the fls., about 1 ft. long, linear, not curved laterally: scape or peduncle 12–18 in. high: fls. bright crimson, 10–12 in an umbel; perianth-segms. oblanceolate, ½in. or less broad, falcate, slightly crisped; filaments suberect, bright red, longer than the segms. Coast region, S. Afr. B.M. 294. R.H. 1912, p. 455; 1913, p. 456. It runs into many forms, as: Var. **Plántii,** Baker (*N. Plántii*, Hort.), has a longer scape, duller fls., and more distinctly clawed segms. Gn. 21:200. Var. **venústa,** Baker (*N. venústa*, Herb.), has bright scarlet fls. produced earlier than any of the other varieties. B.M. 1090 (as *Amaryllis venusta*). Var. **ròsea,** Baker (*N. ròsea*, Herb.), has lvs. darker green than the type: fls. rose-red: seeds oblong instead of globose. B.M. 2124 (as *N. rosea*). Var. **corúsca,** Baker (*N. corúsca*, Herb.), has bulb tunics not chaffy: lvs. broader than in the type, with distinct cross-bars between the main veins: fls. large, bright scarlet. B.M. 1089 (as *Amaryllis humilis*). Gn. 21:200. *N. corusca major* has rich crimson-red fls. Var. **carnòsa,** Hort., carmine rosy. Var. **insígnis,** Hort., is considered by Baker synonymous with the type of the species, but is probably horticulturally distinct. The fls. are said to be rosy.



2475. Nerine Mansellii. (×½)

BB. *Lvs. glaucous, sickle-shaped.*

2. **curvifòlia,** Herb. Bulb ovoid, to 2 in. diam., the coverings pale brown: lvs. 6, appearing after the fls., strap-shaped, curved laterally, thicker than in *N. sarniensis*, about 1 ft. long: scape or peduncle slender and glaucous, 12–18 in. long, the umbel 8–12-fld.: fls. bright scarlet; perianth-segms. hardly crisped, oblanceolate, ¼in. broad, falcate; stamens erect or nearly so, about as long as the perianth-limb. S. Afr. B.M. 725 (as *Amaryllis curvifolia*).—Cult. in the form of var. **Fóthergillii,** Baker (*N. Fóthergillii*, Roem.), which is more robust in all parts (Fig. 2474): fls. more numerous, between crimson and scarlet. R.B. 22:13. Gn. 22, p. 463. G. 3:503; 5:380. Var. **Fóthergillii màjor** (*N. Fóthergillii màjor*, Hort.) is a form with still larger fls. J.H. III. 55:277. F.R. 1:675.

AA. *Stamens and style declined.*

B. *Outer fls. of the umbel opening before the inner ones.*

C. *Segms. distinctly crisped or fluted.*

3. **flexuòsa,** Herb. Bulb subglobose, 1½ in. diam.: lvs. 4–6, appearing with the fls., linear-strap-shaped, arcuate, bright green, ¾in. or less broad, sometimes pustulate: scape flexuous, longer than in the other kinds, sometimes 2–3 ft. long: fls. generally pale pink, the segms. oblanceolate and crisped, ⅙in. broad; stamens declined, the 3 longer ones rather shorter than the segms. Kalahari and central region of S. Afr. B.R. 172. R.H. 1913, p. 456. Var. **pulchélla,** Baker (*N. pulchélla*, Herb.), has glaucous lvs., firmer than in the type: scape not flexuous: fls. pale pink, keeled rose-red. B.M. 2407 and Gn. 21:200. Var. **Sándersonii,** Baker, has peduncle and pedicels more robust and lvs. 1 in. broad: perianth-segms. less crisped, 1¼ in. long, and more distinctly united in cup at base. Var. **álba,** Hort., has white fls. G.C. III. 40:336. **N. Mánsellii,** O'Brien, Fig. 2475, is a fine hybrid between *N. flexuosa* and *N. Fothergillii*. Gn. 56:378. It has very broad fleshy lvs. and bright red slightly irregular fls. This is one of the most interesting kinds.

CC. *Segms. hardly or slightly crisped.*

4. **pùdica,** Hook. f. Bulb globose, about 1 in. diam.: lvs. 4–6, glaucous, 8–9 in. long, suberect, appearing with the fls.: umbels 4–6-fld., the other kinds being 8–20-fld.; fls. white, keeled pink above; segms. oblanceolate, thin, scarcely crisped; stamens declined, the 3 longest a little shorter than the perianth-segms. Original habitat in doubt. B.M. 5901. R.H. 1913, p. 456. F.S. 23:2464. Gn. 21:200. Var. **Élwesii,** Baker (*N. Élwesii*, Leichtl.), has much broader bright green more persistent distinctly veined lvs. with a prominent midrib: fls. more compact and pedicels stouter; segms. pale rose with a darker keel, thicker and more wavy. Var. **álba,** Hort., fls. snow-white.

5. **Bòwdenii,** W. Wats. Bulb variable in size, the largest bottle-shaped and 1½ in. diam. and 2 in. long, freely producing offsets: lvs. ½–1 ft. long and 1 in. or less broad, glossy green, slightly channeled, obtuse: scape nearly cylindrical, 12–18 in. long, bearing a loose 6–12-fld. umbel 9 in. across, the trigonous pedicels 2 in. long; fls. large, rose-pink with keels darker; segms. 2–3 in. long and ½in. wide, recurved and slightly wavy. Cape Colony. B.M. 8117. G.C. III. 36:365. Gn. 77, p. 570. F.S.R. 3:120.—As grown at Kew, the plants are practically leafless when in fl. Var. **pállida,** Hort. (*N. Veìtchii*, Hort.), is pale in color (blush-white): fls. 2¼ in. across, with recurved segms. Gn. 75, p. 484. G.M. 54:742. G.C. III. 58:132.

BB. *Outer fls. opening after the inner ones.*

6. **undulàta,** Herb. Bulb ovoid, to 1 in. diam., the coverings membranaceous and pale: lvs. 4–6, linear, appearing with the fls., bright green, 12–18 in. long and ½in. or less broad: peduncle slender, 12–18 in. long, bearing a centrifugal 8–12-fld. umbel: fls. pale pink, perianth, ¾in. or less long; segms. oblanceolate, very narrow and much crisped. Kalahari region and coast region, S. Afr. B.M. 369 (as *Amaryllis undulata*). Gn. 76, p. 136. Var. **májor,** Tratt. Perianth-limb larger, less crisped.

7. **hùmilis,** Herb. Bulb ovoid, to 1½ in. diam., the coverings membranaceous: lvs. about 6, appearing with the fls., linear, bright green, channeled on the face, about 1 ft. long and ½in. broad: scape or peduncle often smaller than in the other kinds, ½–1½ ft. high: fls. bright pink or rose-red, 10–20 in an umbel, the perianth ¼in. or less long; segms. oblanceolate, acute, crisped; stamens declined, the 3 longer about as long as segms. Coast region, S. Afr. B.M. 726 (as *Amaryllis humilis*). Gn. 21:200. Var. **spléndens,** Hort., is presumably the best form of this species. Fls. purple-crimson.

The following names are mostly important hybrids which in many cases are more popular than the species: *N. amábilis* (N. pudica × N. humilis), rosy, dark-striped. Var. *grandiflòra*, Hort. Van Tubergen, has larger fls.—*N. cándida*, Hort. Pure white, the fls. 15–20, each about 2 in. diam., the segms. undulate: hardly distinguishable from N. flexuosa var. alba. Offered abroad.—*N. críspa*, Hort. Thorburn, scarlet.—*N. élegans* (N. flexuosa × N. sarniensis var. rosea), pink. Var. *carminàta*, cerise. Var. *cærùlea*, shaded blue.—*N. excéllens*, Moore (N. flexuosa × N. humilis var. major), carmine rosy, dark-striped.—*N. excéllens màjor tardiflòra*, Hort.=N. Bowdenii.—*N. Gaìminii*, Hort., is an erect-flowering form of the sarniensis group, with large bright pink fls. "keeled throughout with red:" fls. about 10 in an umbel, each 2 in. across.—*N. Hàylockii* (N. curvifolia × N. flexuosa var. pulchella). One of the oldest hybrids in cult. Raised by Wm. Herbert. The others in this list are more modern.—*N. japónica*, Miq.=Lycoris radiata.—*N. Méadowbankii* (N. sarniensis × N. curvifolia var. Fothergillii).—*N. O'Brìenii* (N. pudica × N. sarniensis var. Plantii). Var. *cærùlea*, Van Tubergen, pale violet, tinged blue.—*N. tardiflòra*, Hort. Van Tubergen, not accounted for by Baker. Fls. bright red in Dec.—*N. Zoroáster*, Hort., is a garden hybrid between N. pudica and N. sarniensis var. corusca.

WILHELM MILLER.
L. H. B.†

NÈRIUM (ancient name for oleander, supposed to be from Greek *neros*, "moist," alluding to the places in which it grows wild). *Apocynàceæ*. The oleander is an old-fashioned evergreen shrub known to everybody, and cultivated everywhere in southern countries. In the North the oleander is a common house plant, being grown in tubs for summer decoration, and ranking in popularity with sweet bay and hydrangea.

Oleanders are erect glabrous shrubs: lvs. in whorls of 3, rarely 4 or 2, narrow, leathery, transversely feather-veined: fls. showy, rose-red, white or yellowish, in terminal cymes; calyx with many glands inside at the base; corolla-tube cylindrical at the base; throat bell-shaped and containing 5 wide or narrow teeth; lobes twisted to the right; anthers 2-tailed at the base and tapering at the apex into a long thread-like appendage; style 1; ovaries 2, forming pods; seeds twisted.—Species probably 3, with varieties. Medit. region to Japan.

The common species, so very widely cultivated, is *N. Oleander*. It attains 7 to 15 feet, and blooms in summer, the flowers being salver-shaped, five-lobed when single, 1½ to 3 inches across, and commonly pink or white, though the colors range from white through creamy white, blush, rose and copper-color, to crimson and dark purple, with variegated forms. It is of easy culture, and is well adapted to city conditions. The chief troubles are scale and mealy-bug. The scale should be sponged off; the mealy-bug is easily dislodged by the hose. Sometimes a plant forms buds which open poorly or not at all. This is often due to the imperfect ripening of the wood. The flowers are borne on the growth of the year, which should be well ripened in June in order to set many strong buds. For this purpose give the plants plenty of light and air, and water more sparingly when the vegetative growth seems to be finished. After flowering, give the plants less water. Protect them from frost in winter; keep them, if necessary, in a light shed. In April, prune back the old wood which has borne flowers and give more warmth and water. The ripened leading shoots can be rooted in a bottle of water. Oleanders are poisonous, and some persons have died from carelessly eating the flowers. Cattle have been killed by eating the foliage. It is said that in California the oleander is immune from the depredations of the gopher.—*Oleanders in the East* (H. A. Siebrecht): The following method of oleander culture has been pursued by the writer with success. Propagation is performed after the flowering period. Good-sized cuttings are taken, and every one grows. When rooted, the cuttings are potted in small pots and kept barely alive over the winter. They will need scarcely more attention than geraniums until February or March, or whenever growth becomes more active. Later in the spring, the young oleanders are planted outdoors in the open ground, in good rich loam or garden soil. (This is sometimes done with ivies or evonymus, but the common method is to plunge the pots outdoors during summer.) Take up the oleanders in September, pot them and bring them indoors for their second winter. The following spring the plants will bloom; but they will not be shapely. The time has now arrived to train them, either as bush plants or crown standards. Top them at whatever height is desired, say 2 or 3 feet, and the plants will make good crowns the same season (i.e., their second summer). Do not allow the plant to bloom the following spring (which is its third spring), and the result will be a fine specimen in full flower for the fourth summer.—*Oleanders in California* (Ernest Braunton): Oleanders are much grown in southern California, and would be extremely popular were it not for black and other scales, which seem to prefer them to everything else. We have five colors here, perhaps all of the same species—white, light pink, dark pink, scarlet and buff. Most of these colors, if not all, can be had in both single and double forms. The writer has never seen an oleander more than 20 feet high, but he thinks they will grow larger. One Los Angeles man planted the red variety twenty-seven years ago for sidewalk trees. (For this purpose, if cleaned of scale when necessary, the oleander is one of the very best.) The trees are heavily pruned and topped every third year. They are now 12 feet high and 6 to 8 inches in diameter at base. Oleanders need no attention here, and are as readily propagated from hardwood cuttings as willow. They are very floriferous, and the inflorescence comes out in large heavy heads, necessitating a close pruning to make them self-supporting.

A. *Fls. not scented.*

Oleánder, Linn. (*N. laurifórme,* Lam.). OLEANDER. ROSE BAY. (Another plant called "Rose Bay" is *Epilobium angustifolium.*) Fig. 2476. Lvs. in 2's or 3's, lanceolate: appendages of the anthers scarcely protruding; segms. of the crown 3–4-toothed. Medit. region, Orient. Gn. 51, p. 81 (fine trees in vases). A.F. 10:265 (Bermuda shrub with a spread of 25 ft.). L.B.C. 7:666 (var. *Loddigesii,* with a variegated fl. and the appendages entire, ovate and obtuse). *N. álbum, N. atropurpùreum, N. cárneum* and *N. ròseum,* Hort., are doubtless varieties. The plant is common in subtropical and tropical countries, sometimes planted in hedges, and sometimes runs wild.

2476. Spray of oleander—Nerium Oleander. (×⅙)

AA. *Fls. scented.*

odòrum, Soland. SWEET-SCENTED OLEANDER. Stout erect shrub: lvs. in 3's, linear-lanceolate: fls. rosy pink, 2 in. across, in clusters of as many as 80, fragrant; appendages of the anthers protruding; segms. of the crown 4–7, long and narrow. Persia, India, Japan. B.R. 74 (fls. double). B.M. 1799 and 2032. G.C. III. 50: suppl. July 8, 1911.—A less robust plant with lvs. commonly narrower and more distant, and angled branches. In wild plants the calyx-lobes of *N. Oleander* are spreading; of *N. odorum* erect. It has the same range of color as the above, and single and double forms. Prop. by layers or cuttings.

WILHELM MILLER.

NERTÈRA (Greek, *lowly;* referring to the habit) *Rubiàceæ.* Creeping herbs, of which one is grown for its handsome profuse berries.

Nerteras are slender perennials, with small opposite lvs. which are stalked or not, ovate or ovate-lanceolate, glabrous or somewhat pilose; stipules present: fls. axillary or terminal, hermaphrodite, inconspicuous, sessile; corolla 4- or 5-lobed; stamens 4 or 5, inserted in base of tube of the tubular or funnel-shaped corolla, the anthers exserted; ovary 2-celled: drupe 2-seeded (two 1-seeded pyrenes), fleshy.—Species about 8, widespread in the southern hemisphere.

depréssa, Banks & Soland. BEAD-PLANT. Glabrous: variable in size, sometimes forming patches: sts. 6–10 in. long, 4-cornered: lvs. 2 lines long, broadly ovate, acute or obtuse, leathery or almost fleshy; petioles about as long as the blades; stipules very small: fls. solitary, greenish. B.M. 5799. F.S. 21:2167 (charming). F.W. 1875:257.—The bead- or coral-bead-plant is a hardy perennial alpine or rock-plant which forms a dense mat of foliage covered with orange-colored translucent berries the size of a pea. It ranges throughout the Andes, from the tropics to Cape Horn. It also inhabits Tristan d'Acunha, and the mountains of New Zeal. and Tasmania. It is prop. by seed or division. The plant needs a sandy soil, with some leaf-mold, and prefers shade in summer and may need some winter covering in the N. It makes a good house plant and well-fruited specimens are occasionally used abroad in fancy bedding as a novelty. The fr. may last from midsummer well into the winter. In S. Calif., *N. depréssa* grows well in the open if it is kept moist and does not receive the direct rays of the sun.

WILHELM MILLER.
L. H. B.†

NERVÍLIA (name refers to the nerved lvs.). *Orchidàceæ.* By some authors made a section of Pogonia with fl.-scape bearing only scales and not lvs., the foliage coming later and separately, stigma broad and lip elongated: the small grayish or reddish fls. are sometimes solitary or twin but usually in a short raceme, nodding: lvs. radical, usually broad, sometimes colored or marked. The species are about 20, from Trop. Afr. to China. They are very little known in cult.

NESÆA: *Decodon.*

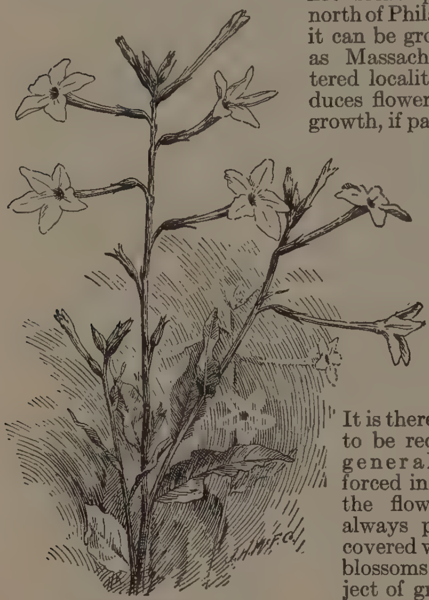
NETTLE: *Urtica.* **Dead N.:** *Lamium.* **False N.:** *Boehmeria.* **Tree N.:** *Celtis.*

NEUWIÈDIA (named for Prince Maximilian von Newied). *Orchidàceæ.* A half-dozen Malayan terrestrial orchids with short caudex and leafy sts.: lvs. lengthened, stalked, strong-nerved: fls. small, mostly white or yellow, sessile or nearly so, in a bracteate terminal raceme or spike; sepals and petals free and mostly similar, connivent or spreading; lip somewhat spatulate, similar to petals; column short. Little cult.; require conditions of warmhouse paphiopedilum. *N. Lindleyi,* Rolfe, has primrose-yellow decurved fls. 1 in. long: 3–4 ft.: lvs. many, 1–2 ft. long, oblanceolate, membranaceous. B.M. 7368. *N. Griffithii,* Reichb. f., has white deflexed pubescent fls. in a short spike; 16 in.: lvs. 4–10 in. long, elliptic-lanceolate, acuminate. B.M. 7425.

NEVIÙSIA (after Rev. R. D. Nevius, who discovered it). *Rosàceæ.* SNOW WREATH. Ornamental shrub sometimes planted for its white flowers.

Deciduous: lvs. alternate, petioled, doubly serrate, stipulate: fls. perfect, in clusters or solitary; calyx-tube flattish; sepals 5, petal-like, spreading, incisely serrate; petals 0; stamens numerous, longer than the sepals, persistent; carpels 2–4, styles slender, curved at the apex, slightly shorter than the stamens: fr. consisting of drupe-like achenes inclosed by the persistent calyx. —One species, found only in Ala. near Tuscaloosa and on Sand Mt. A very distinct genus allied to Kerria and Rubus, well distinguished by its apetalous fls.

The snow wreath is a low or medium-sized shrub with slender wand-like branches, bright green generally ovate leaves and white feathery flowers in clusters arranged wreath-like along the branches. It does not seem perfectly hardy north of Philadelphia though it can be grown as far north as Massachusetts in sheltered localities; and it produces flowers on the young growth, if partly killed back. Even South it does not develop in every situation its full beauty which earned it the name "snow wreath" its flowers are likely to be greenish or dirty white instead of snowy. It is therefore not a plant to be recommended for general planting. If forced in the greenhouse the flowers come out always pure white, and covered with its feathery blossoms it is an object of great beauty. It likes a loamy and well-drained soil and a warm sheltered position.



2477. Nicotiana alata var. grandiflora.

Propagation is by greenwood cuttings under glass, and by seeds.

alabaménsis, Gray. Shrub, 3-6 ft.: branches terete: lvs. ovate to oblong-ovate, acute or acuminate, doubly serrate, minutely pubescent while young, finally nearly glabrous, 1–3 in. long: fls. in clusters of 3–8, rarely solitary, about 1 in. across. June, July. B.M. 6806. G.C. III. 35:229; 41:41. G.M. 53:315. G. 26:135.

Alfred Rehder.

NICÁNDRA (Nicander, poet of Colophon, wrote on plants about 100 B.C.). Syn. *Physalòdes*. *Solanàceæ*. One Peruvian herb differing from Physalis chiefly in the 3–5-loculed ovary and dry rather than fleshy fr., and in the larger and more showy fls., of which the corolla is nearly entire. Lately a second species has been described, perhaps a variant.

Physalòdes, Pers. (*Átropa physalòdes*, Linn. *Physalòdes peruviànum*, Kuntze. *N. physaloìdes*, Gaertn.). Known as Apple-of-Peru, a strong spreading annual, 3–4 ft. high, grown for the showy blue fls. and odd frs.: glabrous: lvs. elliptic or elliptic-ovate, sinuate and toothed, narrowed into a prominent petiole: fls. solitary in the axils, on recurving pedicels, an inch or more across, shaped like a potato flower, the corolla blue or bluish: fr. a thin-walled and nearly or quite dry berry, inclosed in an enlarged, strongly 5-winged calyx. B.M. 2458.—The apple-of-Peru is an old-fashioned garden annual, now rarely seen. It has escaped from cult. in some places in the U. S., and it is now widely distributed in the tropics. It is often confounded with the ground cherry and alkekengi, which are species of Physalis.

N. violàcea, André. Vigorous branched annual, glabrous or sometimes the lvs. hairy on upper side: lvs. subtriangular, the cauline reaching 10 in. long and 5 in. broad, coarsely toothed or lobed: fls. solitary, axillary and short-pedicelled; calyx large, dark violet on lower half, the lobes cordate; corolla violet-blue above and white on lower half, campanulate, to 1½ in. broad. Probably S. Amer. R.H. 1906:208.—Distinguished from *N. Physalodes* particularly by the prominently blue corolla and calyx and similar color on the sts., petioles and peduncles, and the scattered colored hairs on upper surface of lvs.

L. H. B.

NICOTIÀNA (named for Jean Nicot, 1530–1600, of Nismes in Languedoc, consul from the King of France to Lisbon, Portugal, in 1560, who obtained tobacco from a merchant of Flanders, Belgium, which he presented to the court of Portugal and also, on his return to France, to the Queen Catherine de Medici). *Solanàceæ* Herbaceous annuals, perennials or rarely shrubby or arborescent, comprising several stately plants, valued for their rapid growth and large foliage; other species produce showy flowers, and are popular flower-garden subjects; one is the tobacco.

Herbs, mostly viscid-pubescent, of strong odor, possessing narcotic poisonous properties: lvs. alternate, never compound, entire or undulate, mostly sessile or nearly so by a tapering base: fls. hermaphrodite, often regular, long-tubular, mostly opening at night and most fragrant then, in terminal racemes, panicles or thyrses; calyx usually persistent, inclosing the fr., tubular-campanulate or ovoid, 5-parted; corolla salverform, funnelform, or tubular-swollen; limb plicate in the bud, 5-lobed; stamens 5, inserted on the tube, unequal or nearly equal, included; filaments straight, anthers longitudinally dehiscent, ovate or oblong; ovary 2-celled, or 4-celled in one species; ovules many; placenta axillary; style simple; stigma capitate: fr. a 2–4-celled caps., but usually splitting into 4 to several valves; seeds numerous, minute, oblong, somewhat kidney-form, roughened or pitted.—A genus of about 45 species and 54 subspecies, mostly of Trop. Amer., with a few from N. and S. Amer. and 1 from Austral.

Latest publications: Comes, "Monographie du genre Nicotiana," 1899; Splendore, "Sinossi descrittiva ed iconographia dei semi del genrere Nicotiana," 1906; Setchell, "Studies in Nicotiana," 1912; "Tobacco-culture," United States Department of Agriculture, Farmers' Bulletin No. 571, 1914.

Nicotianas are easily cultivated, but in northern latitudes require a hot exposure and a deep rich loose loamy soil, rich in lime and potash, both of which may be supplied from wood-ashes. As the seeds grow slowly in cool weather, they should be started in early spring under glass and kept moist and warm. For tobacco, in districts farther north, hotbeds will secure rapid growth, but in other localities coldframes with a southern exposure should be used. The soil should be a loose loam of high fertility, and thoroughly drained. In the fall, forty pounds of lime and two hundred pounds of stable-manure to 100 square feet of bed should be turned under. In the spring, about two weeks before sowing the seed, twenty pounds of cottonseed-meal or castor pomace, one pound of acid phosphate, and one-half pound of carbonate or sulfate of potash to 100 square feet of bed-area should be

2478. Nicotiana alata var. grandiflora, commonly known as N. affinis. (×⅕) thoroughly spaded into the soil to a depth of 4 or 5 inches, and the bed-surface finely pulverized. If possible, the soil should then be sterilized with steam to prevent fungous diseases and the growth of weed seeds. The seed should be sown at the rate of an even teaspoonful of dry seed to 100 square feet of bed. In order to secure an even distribution of the seed, it is thoroughly mixed into two quarts of land-plaster, finely sifted wood-ashes or bone-meal. Three sowings should be made to insure an even distribution over the bed, the light color of the filler material serving to indicate the evenness of the distribution. The seed must be covered by going over the bed with a roller, or packing with a plank. When young, nicotianas will stand considerable frost, but become more sensitive with age. They are well adapted to pot or tub culture and are fine for summer porch-decoration. *N. alata*, best known in the trade as *N. affinis*, and *N. Sanderæ* are the most popular flower-garden plants. Of the larger species for subtropical bedding, *N. glauca*, *N. tomentosa*, and *N. Tabacum* are best.

A. *Fls. racemose, paniculate, or axillary, extra-axillary, and solitary; corolla salverform, white or colored, tube long, cylindric; limb-segms. obtuse or acute:* (*Nos. 1–9. Subgenus Petunioides.*)

B. *Ovary 2-celled.*

C. *Lobes of corolla acute.*

D. *Color of corolla greenish to purplish or lobes only white.*

E. *Corolla 6–7 times longer than the calyx.*

1. **longiflòra**, Cav. Erect annual or perennial, 2–3 ft. tall: st. slender, bristly-scabrous: lvs. somewhat clasping, spatulate to lanceolate, prominently undulate, obtuse or acute: fls. 4 in. long, extra-axillary in terminal loose racemes; calyx striate, tubular-campanulate, 5 unequal, erect, linear-lanceolate teeth; corolla villous, salverform, night-opening, fragrant, nearly 7 times longer than the calyx; tube slender, swollen above, green or pale violet; lobes ½in. long, yellowish violet without, white within, nearly equal, ovate-lanceolate, obtuse, often emarginate; filaments adnate, near the throat unequal, 1 shorter; anthers yellowish violet; style shorter than the stamens: caps. nearly equaling the calyx. Texas to Chile and Argentina.—Rare in cult., and inferior to *N. alata*. Becomes annual in northern gardens.

EE. *Corolla 4–5 times longer than the calyx.*

2. **alàta**, Link & Otto (*N. decúrrens*, Agardh). Herbaceous, perennial: st. erect, slender, 2–3½ ft. tall, branching: lvs. sessile, decurrent, oblong-spatulate to ovate-elliptic; apex obtuse, or acute to nearly acuminate; margin entire or distantly repand-dentate: fls. spreading in an open raceme; calyx hirsute, tubular, with 5 unequal subulate teeth; corolla villous, night-opening, fragrant; tube slender, yellowish green, 4–5 times longer than the calyx, swollen above; limb oblique, nearly 2 in. across, pale violet beneath, white within; lobes ovate, acute, often emarginate; stamens unequal, not exserted; style exserted: caps. oblong, shorter than the calyx. Brazil, Uruguay, and Paraguay. Gt. 1010. It is doubtful whether the species *N. alata* is in cult., the garden forms being the varieties. Var. **pérsica**, Comes (*N. pérsica*, Lindl.). Lower lvs. subpetiolate, oblong-spatulate, base often subcordate, repand above, all somewhat clasping and auricled or decurrent: corolla-tube shorter, limb greenish yellow without, lobes slightly unequal, emarginate. Brazil. B.R. 1592.—Intro. into the U. S. as early as 1906. Not much cult. Var. **grandiflòra**, Comes (*N. affinis*, T. Moore, under which name it is universally known in gardens). Figs. 2477, 2478. Fls. very large, and very sweet-scented; tube much dilated, limb yellowish without. G.Z. 1882: 253–5. G.C. II. 16:141. Gn. 34, p. 520; 42, p. 126; 50, p. 212; 56, p. 384. Gng. 5:182. G. 27:323.—Known only in cult. An extremely popular plant, blooming freely throughout the season until killed by frost. On account of its slender habit, it should be planted in a place protected from strong winds. It is apparently perennial, but is treated as a half-hardy annual. It self-sows, and often maintains itself from year to year in the Middle States and the S. In the warmer parts of the S., the roots live over winter with a little protection. Fall-sown seedlings make excellent pot-plants in the winter, the fls. opening in the early evening and closing in the morning, and are very fragrant.

2479. A good border effect with Nicotiana.—N. sylvestris.

DD. *Color of corolla entirely white.*

3. **sylvéstris**, Spegaz. & Comes. Figs. 2479, 2480. Herbaceous, perennial, glandular-pilose throughout: st. tall, leafy below, branching above: lvs. sessile, broad, oblong-spatulate; the lower dilated at the base, half-clasping and auricled, slightly decurrent, the apex, rotund or obtuse; the upper acute, margin reflexed: fls. drooping, in short racemose panicles; pedicels nearly equaling the calyx; calyx 5-angled, somewhat swollen, short and unequally toothed, teeth ovàte-acute; corolla white, fragrant, salverform, pilose; tube 6–7 times longer than the calyx, above somewhat inflated; limb white within; lobes nearly equal, ovate-triangular, often emarginate, becoming reflexed. Argentina. G.C. III. 26:357. G.W. 7:230; 12:318. A.F. 24:600. G.M. 52:48. Gn. 59, p. 186. Gn. W. 15:442.—The lvs. are rugose, veiny, and more attractive than in *A. alata* but the limb of the fl. is less oblique, the tubes more swollen

and does not close in the morning on cloudy days. One of the novelties in 1899 and 1900.

DDD. *Color of corolla rose.*

4. **Sánderæ,** Hort. Sander (*N. alàta* × *N. Forgetiàna*). Herbaceous, annual, viscid-pubescent: sts. 2–3 ft. tall, of bushy habit: basal lvs. large spatulate, undulate; st.-lvs. oblong-lanceolate, short-petioled, acuminate, undulate: fls. bracteolate, in large loose panicles; corolla salverform; tube cylindric, 3 times the length of the calyx, swollen above, greenish yellow tinted with rose; limb oblique; lobes elliptic, acute, often emarginate, carmine-rose. Originated in 1903 by Sander & Sons, St. Albans, England, as a cross between *N. alata* and *N. Forgetiana*. A.G. 25:483. F.S.R. 2:216. F.E. 20:434. G. 26:141; 27:321. G.C. III. 34:256; 39:61. G.M. 47:578; 48:465. Gn. 67:16. G.W. 8:559. R.B. 31:25. R.H. 1905:16.—An attractive and popular garden plant intro. into U. S. in 1904.

CC. *Lobes of corolla obtuse or rounded.*

D. *Lvs. petioled.*

5. **acuminàta,** Hook. (*Petùnia acuminàta*, Graham. *P. viscòsa*, Miers. *N. diversifòlia*, Nees?) Herbaceous, annual, viscid-pubescent: st. slender, branching: lvs. ovate-lanceolate, undulate, sometimes subcordate, narrowed into a short petiole, apex long-acuminate: fls. loose-racemose; calyx glandular-pubescent, membranaceous-scarious, 5 nerves ending in narrow, linear, unequal teeth; corolla white, about 3 in. long; tube green-veined, slightly curved, swollen above, nearly 5 times as long as the calyx; limb 5-parted; lobes small, obtuse, emarginate expanded, green-veined without: caps. nearly equaling the calyx. Chile. B.M. 2919.—Not common in cult., under which it appears to be annual, but in its native habitat it is perennial.

DD. *Lvs. sessile.*

E. *Fls. rose-colored.*

6. **Forgetiàna,** Hort. Sander. Herbaceous, annual: st. 2–3 ft. high, branching from the base: lvs. papery, soft, pubescent; basal lvs. oblong-lanceolate, largest about a foot long, obtuse, tapering to a winged petiole, slightly undulate; st.-lvs. similar, but smaller, ovate, with decurrent blades: fls. in broad loosely branched panicles; branches slender, glandular-pubescent; lower bracts leafy, narrow, acute, becoming smaller upward; pedicels slender, shorter than the fls.; calyx small, 5-toothed, covered with stiff hairs; teeth unequal, very slender, rigid; corolla narrow, funnelform, 1–1¼ in. long, 1 in. diam.; sparsely hairy; lobes of the limb nearly equal, triangular, obtuse; stamens included; filaments hairy at base, jointed above their attachment to the corolla; ovary glabrous. Brazil. B.M. 8006.—Intro. into cult. about 1901 but not much in the trade, being used mostly in hybridizing.

EE. *Fls. greenish.*

F. *St. pubescent throughout.*

7. **noctiflòra,** Hook. (*N. longiflòra noctiflòra*, Voss). Herbaceous, perennial, glandular-viscid, hairs appressed: st. 2–3 ft. tall, slender, branching: lvs. petiolate, oblong-lanceolate, sinuate or undulate-plicate, the lower oblong-obtuse, the upper nearly sessile, linear-lanceolate, acute: fls. pedicellate, horizontal, in terminal panicles; calyx tubular, with 5 unequal, narrow, lanceolate, acute teeth; corolla salverform, night-opening, fragrant, greenish purple without, white within, 3–4 times longer than the calyx; tube cylindric; lobes equal obcordate, emarginate, oblong; nectar-ring orange, thickened: caps. longer than the calyx. Argentina and Chile. B.M. 2785. Var. **albiflòra,** Comes, has the fls. nearly glabrous, glaucous, and greenish white or sometimes pure white without instead of purplish, or sometimes with a purplish vein in each corolla-lobe. Argentina.—Very decorative. Intro. into U. S. from Italy in 1908.

FF. *St. glabrous above.*

8. **suavèolens,** Lehm. Herbaceous, annual or biennial, usually viscid: st. 1–2 ft. tall, densely villous at base, glabrous above: lvs. at base subpetiolate, spatulate, obtuse, above ovate-lanceolate, acute, undulate, petiole decurrent, the uppermost nearly sessile or clasping, acuminate, villous: fls. pedicellate, nodding, distant, bracteolate, in terminal racemes; calyx 5-toothed, striate, tubular, pubescent; teeth linear-lanceolate, narrow, acuminate, unequal; corolla greenish purple, night-opening, fragrant, pubescent, salverform; tube slender, cylindric, striate, 4 times longer than the calyx; limb purplish without, white within; somewhat 2-lipped, the upper lobes very small, all subrotund, obtuse or emarginate: caps. ovate, obtuse, nearly equaling the calyx. Austral.—It is said to grow in moderate shade. Var. **undulàta,** Comes (*N. undulàta*, Vent., not Ruiz & Pav.). The plant is taller: lvs. large, undulate: fls. larger. B.M. 673. Var. **macrántha,** Comes (*N. fràgrans*, Bern.). The st. is glabrous: lvs. oblique, subcordate-ovate, sinuate-repand, acute: corolla large, white, mouth expanded; lobes obtuse. B.M. 4865.

2480. Nicotiana sylvestris. (×¼)

BB. *Ovary 4- to many-celled.*

9. **quadriválvis,** Pursh. Herbaceous, annual, viscid-pubescent: st. erect, or branching: lvs. 4–6 in. long, petiolate, oblong, the upper nearly sessile, entire, lanceolate, acute; margin often somewhat revolute: fls. few on short slender pedicels; calyx-teeth linear, corolla tubular, swollen below, tube about 1 in. long; limb 1½ in. diam.; lobes ovate, obtuse, dark purplish without, white within: caps. 4-celled, subglobose, nearly equaling the calyx.—Formerly cult. by the Indians and still grown by them to a slight extent; probably does not occur outside Indian cult. and gardens; possibly only a cult. mutant of *N. Bigelovii*, as it appeared in Setchell's pedigree cultures of that species. Fresh lvs. said to smell like a goat, but the odor disappears on drying. **N. multiválvis,** Lindl., known only from Indian cult. in Ore. and Wyo., differs in the many-celled indehiscent caps., and many-lobed corolla-limb.

AA. *Fls. racemose or paniculate; corolla salverform; tube relatively broad or swollen, usually yellow or mixed with white or red; limb-segms. obtuse or acute. (Nos. 10–17. Subgenus Rustica.)*

B. *Plants glabrous and glaucous.*

10. **glaùca,** Graham (*N. arbòrea,* Dietr.). Erect, tree-like, up to 20 ft. tall, glaucous-blue all over: st. branching: lvs. long-petioled, unequally subcordate-ovate, acute, somewhat repand: fls. pedicelled, pedicels incurved in fr., in loose, terminal, bracted panicles; calyx tubular, 5-toothed, teeth acute, unequal, somewhat ciliate; corolla yellow, tube scarcely incurved, somewhat swollen above; mouth contracted, softly woolly; limb small, lobes ovate, very short, acute: caps. inclosed in the calyx. Argentina, Paraguay, Bolivia. B.M. 2837. G. 26:571.—Frequently cult. for its stately habit and striking glaucous-blue foliage which sometimes develops purplish tints. It has escaped from cult. and runs wild in Texas and Calif. Usually does not bloom in the northern states. Easily grown from seed.

BB. *Plants pubescent.*

C. *Lvs. sessile.*

D. *Corolla not over 3 times longer than the calyx; stamens much exserted.*

E. *The corolla without a bright red margin.*

11. **tomentòsa,** Ruiz & Pav. (*N. colossèa,* André). Herbaceous or woody, perennial, viscid-pubescent: st. reaching 10 to 20 ft., diffusely branched from the base upward: branches leafy, terete, ascending: lvs. 10–18 in. long by 4–6 in. wide, obovate-oblong, acuminate, narrowing into a very broad undulate, winged petiole with a clasping base, pale green above, paler beneath, with conspicuous midrib and veins: panicle terminal, nearly a foot long and broad, branches ascending, loose-fld., tubercled at the articulations of the pedicels; bracts narrow, caducous; pedicels ½–⅔in. long; fls. inclined, 1½ in. long; calyx broadly terete, ½in. long, smooth, green, base rounded; lobes unequal narrow, obtuse, shorter than the tube; corolla slightly incurved, pale green and pubescent without; tube somewhat exceeding the calyx-lobes; lobes ovate, obtuse, spreading, yellowish tinged with red within; stamens suberect, twice as long as the corolla-lobes; ovary conical, glabrous; style longer than the stamens, reddish; stigma 2-lobed. Brazil. B.M. 7252. G.C. III. 9:83. Gng. 1:97.—A remarkably valuable plant for large and rapid growth. Very useful in making subtropical effects. Re-described by André from plants that came up in soil received with Brazilian orchids which were sent to France. It began to attract attention in France about 1899. It usually has reddish sts. which add to the bold effect. Seeds should be started under glass. Var. **variegàta,** Hort., has mottled and margined foliage. R.H. 1893, p. 9. G.M. 37:61.

EE. *The corolla with a bright red margin.*

12. **isodéndra,** Ricker (*N. arbòrea semperflòrens,* Ament. *N. colossèa variegàta* × *N. macrophýlla*). A tree-like perennial herb, viscid-pubescent throughout: st. erect, 6–18 ft. tall, somewhat branching above: lvs. sessile, ovate to elliptic, acute, undulate: fls. in loose, long-pedicelled, terminal panicles, drooping; tubes greenish, 2 or more times the length of the calyx; corolla broader and whiter than in *N. tomentosa* with a bright red margin. A hybrid between *N. tomentosa variegata* and *N. Tabacum macrophyllum* originated in Germany in 1903 by Franz Ament. It is poorly described and as yet little known in the U. S. M.D.G. 19:208. Gt. 54, p. 43.—Flowers continually throughout the season.

DD. *Corolla 4 times longer than the calyx; stamens slightly or not at all exserted.*

13. **Lángsdorffii,** Weinm. Herbaceous, annual, pilose to downy: st. 2–3 ft. tall, branching: lower lvs. ovate with a short narrow petiole, undulate, obtuse; upper lvs. ovate-elliptic or somewhat lanceolate, sessile, decurrent, acute: fls. paniculate, drooping; calyx 5-toothed, upper teeth longest; corolla greenish yellow, salverform, the tube clavate and swollen above, 3 times longer than the calyx; limb yellow within, obsoletely 5-lobed; lobes obtuse, somewhat emarginate: caps. obtuse, slightly longer than the calyx. Brazil and Chile. B.M. 2221, 2555.

CC. *Lvs. petiolate.*

D. *Corolla 2–3 times longer than the calyx.*

E. *Fls. yellowish or greenish.*

F. *Plants up to 6–7 ft. tall, robust with large heavy lvs.*

14. **wigandioìdes,** Koch. Herbaceous, perennial, of shrubby habit, glandular-pubescent: st. erect, 6–9 ft. tall, somewhat branching below: lvs. petiolate, ovate, acuminate, undulate: infl. paniculate; fls. pedicelled, drooping; calyx campanulate, teeth unequal, acuminate, glandular-pubescent; corolla salverform, yellowish white; limb somewhat reflexed; lobes broadly ovate, cuspidate; stamens included, filaments tomentose at base; style clavate; stigma green; ovary conical, ring fleshy, reddish, surrounding the base. Sent to the Cracow Botanical Garden from Colombia about 1852 by Warscewicz. B.H. 23:331.—A very striking plant for bold tropical effects.

FF. *Plants not over 4 ft. tall, slender and smaller-lvd.*

15. **rústica,** Linn. Herbaceous, annual, sometimes bi- or triennial, somewhat viscous pubescent: st. about 3 ft. tall, branching below: lvs. petiolate, large, thickened, ovate or oblong, cordate or subcordate, entire or rarely undulate, obtuse: fls. day-opening, pedicellate, in terminal racemes, yellowish or greenish, about 1 in. long; tube cylindric, inflated above, contracted at the throat, slightly villous, 2–3 times longer than the calyx; limb glabrous, yellowish; lobes short, rounded: caps. ovate to subglobose, apex often somewhat umbilicate. Mex. and Texas. Barton, Fl. 1:25.—Said to be the first species of tobacco intro. into Eu. Its use was made known by John Nicot for whom the genus was named.

EE. *Fls. reddish yellow.*

16. **glutinòsa,** Linn. Herbaceous, viscid-pubescent throughout: st. angular above: lvs. petiolate, subrotund to ovate, cordate, abruptly acuminate: fls. in terminal racemes, drooping, bracteolate; calyx somewhat 2-lipped, lower lobe 2-parted, upper lobe 3-parted, teeth lanceolate-acuminate, the upper largest, rather long, recurved; corolla reddish yellow, viscid-pubescent without, twice longer than the calyx; tube incurved, swollen above; limb 5-parted; lobes ovate, acute: caps. ovate, obtuse, included within the calyx. Peru and Bolivia. And. Bot. Rep. 484.—Intro. into the U. S. from Italy in 1908.

DD. *Corolla 5–6 times longer than the calyx.*

17. **paniculàta,** Linn. Herbaceous, annual, viscid-pubescent: st. 2–3 ft. tall, simple, angular above, branching: lvs. petiolate, subcordate, ovate or suborbicular, obtuse or abruptly apiculate, the upper ovate, acute: fls. pedicellate, bracteolate, in large terminal panicles; calyx with 5 nearly equal linear teeth; corolla yellowish green, salverform, tube clavate, glabrous, nearly 6 times longer than the calyx, contracted at the throat; limb plicate, green, very short, becoming revolute; lobes acute: caps. ovate, obtuse, slightly longer than the calyx. Peru. R. &. P. Fl. Peruv. 129.—Not much cult.

AAA. *Fls. in panicled corymbs; lobes acute; corolla funnelform, throat more or less inflated, red or rarely white. (Subgenus Tabacum.)*

18. **Tabácum,** Linn. TOBACCO. Herbaceous, annual, sometimes bi- or triennial and somewhat shrubby at

base, viscid-pubescent: lvs. thin, half-clasping, somewhat auricled, sessile, more or less decurrent, ovate, oblong, elliptic or lanceolate: fls. pedicellate in bracted panicles or racemes; calyx oblong, teeth unequal; corolla woolly without, 2–3 times longer than the calyx; tubes white or whitish; limb drooping, rose-colored or red; lobes acute or acuminate: caps. nearly equaling the calyx. Trop. Amer. Nees Fl. Germ. 24:461.—The fls. are diurnal. Cult. from earliest times by the Indians and often runs wild. Its commercial cult. being an agricultural subject is not discussed in this work. It is a striking plant in the garden. Var. **angustifòlia,** Comes (*N. chinénsis,* Fisch.). This is a narrow-lvd. variety from China and Java of which there are several hybrids. Intro. into the U. S. in 1906. Var. **macrophýlla,** Schrank. A large-lvd. variety with large red fls., of which there are several horticultural forms, variously listed in the trade as *N. grandiflòra purpùrea, N. atropurpùrea grandiflòra, N. rùbra.*

N. Bigelòvii, Wats., with sts. 1–2 ft. tall, fls. white 1–2 in. long, is of interest as being the possible origin of N. quadrivalvis and N. multivalvis. Calif.—*N. trigonophýlla,* Dunal, has sts. 15 in. tall: lvs. triangular, sessile, somewhat clasping, 2–2¼ in. long, ½–¾in. wide: corolla yellowish green, ½–⅝in. long: viscous pubescent throughout. Utah to Mex. and Calif.

P. L. Ricker.

NICOTÙNIA is a name given by the undersigned to hybrids of Nicotiana and Petunia offered in 1893. They were originally described as follows: "The plants have slender, drooping or trailing tomentose green, red and purple stalks and lvs. twice or three times as large as the petunia; the fls. are handsome, white, pink, carmine or striped and borne in plenteous profusion. No seed is ever produced, but they are very readily multiplied by cuttings."

These plants have unfortunately vanished from cult. They were, of course, annuals. They were semi-trailing plants, the lvs. covered with abundant short, woolly hairs. The cross was *Petunia hybrida* var. *grandiflora* × *Nicotiana wigandioides* var. *rubra,* the former probably being the seed-parent. The singular thing about the cross was the fact that the root seemed in all cases to be paralyzed and very defective, though the tops in all the many hybrids produced grew with much vigor. The blooms were beautiful, and it is a pity that the plants were not grafted on tobacco roots. Subsequently several parties have reported crosses of the tobacco and petunia and also tobacco and salpiglossis.

Luther Burbank.

NIDULÀRIUM (from Latin *nidus,* a nest). *Bromeliàceæ.* Warmhouse epiphytes, requiring the treatment of billbergia.

Flowers perfect, borne in compound heads, the petals joined at the base and not ligulate (in all the typical species); anthers attached mostly on the back (in some related plants attached mostly at the base): lvs. strap-shaped, ovate or oval, in dense rosettes, the fls. mostly sessile, red, blue, or white; the inner lvs. of the rosette, here called bract-lvs., are usually highly colored and constitute most of the merit of some species.—About 15 Brazilian species, by some referred to Karatas and other genera, but by Mez (DC. Monogr. Phaner. 9) kept distinct.

During the spring and summer nidulariums will require plenty of heat and moisture, this being their growing season. About the middle of January or when they show signs of becoming more active, they may be placed in a house with a night temperature of 65°. Before the plants are started up too much, they should haveany necessary repotting. They do well in either pans, cribs, or wire baskets. The compost should be some light porous material, such as fern fiber, sphagnum moss, or fibrous peat, adding some broken crocks and charcoal for drainage. Gradually increase the temperature at night until by summer they are having 75° with 10° to 15° higher during the day. Dampen the walks and under the benches so as to produce plenty of atmospheric moisture. With the increased temperature, do not allow them to become dry at the root, as they like an abundance of moisture. While nidulariums like plenty of light, they will need some shade when the sun is powerful, so they will not burn. After flowering they should be encouraged to make new growth. During the winter the temperature may be dropped to about 60° at night and the atmosphere should be kept drier. They will need only a very little water during the dark days of winter, just enough to keep them alive. Nidulariums are increased by suckers like many others of the Bromeliaceæ. These may remain on the parent plant until of sufficient size and strength, when they should be taken off and placed in small pots, using the same compost as above. Place these under a frame with bottom heat and a humid atmosphere. In a short time, they begin to make growth, when they may be given the same treatment as the old plants. Sponge often for scale. (J. J. M. Farrell.)

A. *Fls. white.*

Innocéntii, Lem. (*Karàtas Innocéntii,* Ant.). Stemless and stoloniferous: lvs. about 20, in a dense rosette, strap-shaped, about 1 ft. long, broadest near the middle, with many small, spiny teeth, green but more or less tinted brown or red, the oval bract-lvs. bright red: fls. in a dense head, white. I.H. 9:329.—Named for the Marquis de St. Innocent, amateur, of Autun, France. There is a form with yellow-striped lvs. I.H. 41:5. This species is one of the best nidulariums.

striàtum, Baker (*N. Makoyànum,* Morr., not Hort. *Karàtas neglécta,* Baker). Lvs. 8–12 in. long, strap-shaped, fine-toothed, prominently striped with central bands of white and shading to cream-color toward the margin, the body color deep green and not brown-tinted. G.C. III. 8:183 (desc.).—A good species.

AA. *Fls. blue or violet.*

Scheremetiéwii, Regel (*Karàtas Scheremetiéwii,* Ant.). Lvs. 10–15, in a short rosette, lanceolate, 10–18 in. long, with many small but conspicuous spiny teeth, rather firm, bright green above and pale green beneath, the bract-lvs. bright red and showy, the points recurving: fls. blue, in a small head. Brazil. Gt. 1858:224.

fúlgens, Lem. (*N. píctum,* Hort. *Guzmània picta,* Lem.). Lvs. 15–20, in a dense rosette, strap-shaped, with large, strong teeth, mottled with green of different shades, paler and scurfy beneath, the bract-lvs. oval and scarlet: fls. blue. J.F. 4:411.

N. amazónicum, Lind. & Andr.=Canistrum.—*N. Bindòtii,* Morr.=Aregelia.—*N. Carolínæ,* Lem.=Aregelia.—*N. Chantrieri,* André, is a hybrid of N. Innocentii and N. fulgens, with brilliant red bract-lvs., obtained by Chantrier Frères, France. R. H. 1895:452.—*N. Líndenii,* Regel=Canistrum.—*N. mèdeo-píctum,* Hort. Lvs. with dark blotches on a green ground and broad white bands lined with green in the center. Brazil.—*N. Morriniànum,* Makoy=Aregelia.—*N. príniceps,* Morr.=Aregelia.—*N. tríste,* Regel=Aregelia.

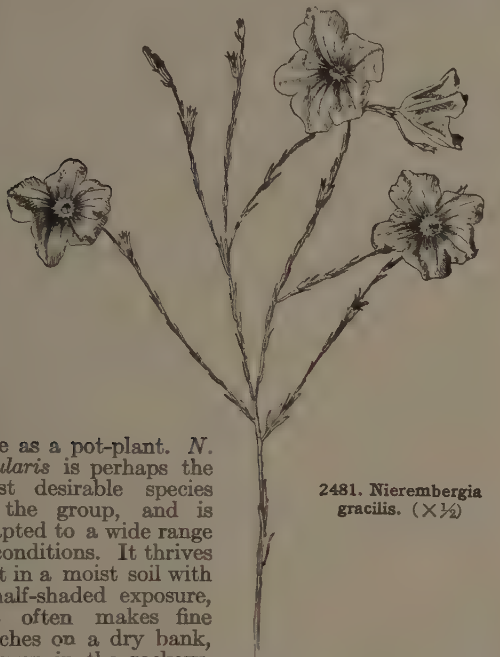
L. H. B.
George V. Nash.†

NIEREMBÉRGIA (for John E. Nieremberg, 1595–1658, a Spanish Jesuit and first professor of natural history at Madrid). *Solanàceæ.* Cup-Flower. Mostly tender perennial herbs valued chiefly for the open border or for pot-plants; they are mostly of prostrate habit, with showy pale violet or white flowers borne freely through the summer and autumn.

Stem decumbent or creeping, rarely suberect, diffusely branched, the branches usually slender and nearly glabrous: lvs. alternate, scattered, entire: fls. borne singly on the tips of young shoots, mostly white with a purple center; calyx 5-parted, tubular or bell-shaped; sepals spreading; tube of corolla long, slender, attenuated below, abruptly expanded above into a broad bell-shaped, saucer-shaped or funnel-shaped limb, which has 5 broad, obtuse lobes: caps. 2-valved.—About 25 species from Trop. and Subtrop. Amer., allied to

Petunia and characterized by the long and very slender tube of the corolla.

Several species of Nierembergia have distinct value for certain purposes. *N. gracilis* makes an excellent pot- or basket-plant, and is also popular for the border. *N. frutescens* does well in the open, but is more desirable as a pot-plant. *N. rivularis* is perhaps the most desirable species of the group, and is adapted to a wide range of conditions. It thrives best in a moist soil with a half-shaded exposure, but often makes fine patches on a dry bank, or even in the rockery. Both *N. gracilis* and *N. frutescens* thrive in a loose, rather moist soil, but are not impatient of dryness. These three species endure winters without protection in the latitude of New York.



2481. Nierembergia gracilis. (×½)

Nierembergias are propagated chiefly by cuttings taken in the fall, or by seeds. *N. rivularis* is most readily increased by dividing the creeping stem where it has rooted at the nodes. As most species are tender, they are best stored indoors, a cool greenhouse being best, where they may receive plenty of light and air. It is best to cut them down almost to the soil when setting them away for the winter.

A. *St. prostrate or creeping: branches ascending.*

B. *Fls. creamy white, sometimes slightly tinted with rose or blue.*

rivulàris, Miers. WHITE-CUP. Whole plant glabrous: st. slender, creeping, rooting freely at the nodes, forming a dense mat, the branches seldom rising over 6 in. high: lvs. oblong to oblong-spatulate, obtuse membranaceous, variable in size, with a long, slender petiole: fls. sessile or short-peduncled; calyx cylindrical, the lobes oblong-lanceolate, slightly spreading; corolla-limb broadly bell-shaped, 1–2 in. broad; throat golden yellow. La Platte River, S. Amer. B.M. 5608. J.H. III. 31:311. Gn. 23, p. 188; 25, p. 145; 64, p. 113; 66, p. 431. G. 19:33.—A very adaptable and desirable species for a stream bank, dry border or alpine garden. The fls. are large and beautiful. It is difficult to eradicate after once established, as small pieces of the st. will take root and grow.

BB. *Fls. white, with purple center.*

gràcilis, Hook. (*N. filicaùlis*, Hort.). Fig. 2481. Branches very slender, ascending 6–8 in., slightly downy: lvs. scarcely ½in. long, linear or slightly spatulate, those on the younger branches somewhat hairy: limb of corolla spreading, convex, white tinged and veined with purple toward the center, throat yellow. Argentina. B.M. 3108. G. 29:255.—A charming little plant for the hanging-basket. A garden form, var. **Crozyàna**, Hort., has fls. tinted lilac and appears to be more floriferous than the type. F.S. 14:1410.

BBB. *Fls. pale lilac.*

Veìtchii, Berkeley. St. 8–12 in. long, with slender, glabrous or slightly pubescent branches: lvs. ½–1 in. long, short-petioled or sessile, the upper linear, the lower broadly spatulate: calyx-lobes linear-oblong, recurved; corolla-tube ½–¾in. long, white, the limb broadly bell-shaped, pale lilac. Trop. Amer. B.M. 5599. F. 1872, p. 141.

AA. *St. nearly erect.*

frutéscens, Dur. (*N. fruticòsa*, Hort.). TALL CUP-FLOWER. St. 1–3 ft. high, much branched, shrubby: lvs. scattered, linear: fls. about 1 in. broad, the limb saucer-shaped, white tinted with lilac or blue; throat yellow; handsome. Chile.—The fls. resemble *N. gracilis* in color, but are much larger. Valuable in the greenhouse or for the border. As a pot-plant it makes a fine bush and bears fls. almost continuously. It can be used as a bedding plant with excellent results if started under glass and transplanted. G. 33:109, 595. H.F. II. 10:9.—A garden form, var. **grandiflòra**, Hort. (*N. grandiflòra*, Hort.) has somewhat larger fls. than the type. Var. **albiflòra**, Hort. Fls. white, appearing well with the foliage. Var. **atro-violàcea**, Hort. Pretty plants, very compact, with dark violet fls. Reproduces well from seed.

S. W. FLETCHER.
A. C. HOTTES.†

NIGÉLLA (diminutive of *niger*, black; referring to the color of the seeds). *Ranunculàceæ.* LOVE-IN-A-MIST. DEVIL-IN-A-BUSH. FENNEL-FLOWER. Hardy annuals grown for their interesting flowers and seed-pods which are often surrounded by the much-divided involucre.

2482. Nigella damascena.

Stems erect: lvs. finely divided, alternate: fls. showy, white, blue or yellow; sepals 5, regular, petal-like, deciduous; petals 5, with hollow claws, notched or 2-lobed: carpels 3–10, fusing at the base into 1 cavity, cells opening at the top when mature; seeds many, black and hard.—About 12 species, including Garidella; mostly natives of the Medit. region. Following 3 are the only species now used in Amer.

Nigellas require little care. The seed should be sown in the open border in good soil any time after the land is fit to work in early spring, as the plants are entirely hardy. The seedlings should be thinned, if necessary, to a distance of about 8 inches. They seldom succeed well if transplanted. If the seeds are sown in early autumn, the plants may withstand a mild winter and be ready to flower earlier the next summer. By planting at different seasons the plants may be continued in beauty nearly throughout the summer. The seeds of *N. sativa*, Linn., or black cummin, are sometimes used as seasoning in the Old World.

damascèna, Linn. Fig. 2482. Height 1–2 ft.: lvs. bright green, very finely cut: fls. white or blue, large; involucre very dense and fine; styles erect in the fr., nearly as long as the caps.: fr. not divergent at top. Summer. S. Eu. B.M. 22. Gn. 37, p. 130; 63, p. 165. J.H. III. 51:61. Gn.M. 5:296. Var. **nàna,** Hort. A dwarf form with very large fls.

hispánica, Linn. Lvs. much divided, but less so than in the preceding: fls. deeper blue than the last, with deep red stamens; involucre absent; styles rather spreading: fr. divergent at top. July. Spain and N. Afr. B.M. 1265. Gn. 37:130. Var. **Fontanesiàna,** Hort. (*N. Fontanesiàna*, Hort.). Much like the type, but said to flower 2 weeks earlier. Var. **álba,** Hort. Plant 18 in. tall: fls. white. Var. **atropurpùrea,** Hort. Fls. purple.

integrifòlia, Regel. Lvs. less divided than either of the above species: fls. differing in being bell-shaped. Cent. Asia. B.M. 8245. G.C. III. 44:227.

K. C. Davis.

NIGGER-TOE: Nuts of *Bertholletia*.

NIGHT-BLOOMING CEREUS: *Cereus*, and other genera mentioned on p. 721.

NIGHTSHADE: *Solanum nigrum*. **Deadly N.:** *Atropa Belladonna*. **Enchanter's N.:** *Circæa*. **Three-leaved N.:** *Trillium*.

NINE-BARK: *Physocarpus*.

NINTOÒA (East Indian name). A name proposed in 1830 by Robert Sweet for certain species of Lonicera (see page 1910). *N. japonica*, Sweet=*Lonicera japonica*.

NÌPA (native name in Molucca). *Palmàceæ*. One species of palm widespread along tidal rivers and estuaries, Ceylon to the Philippines and Australia, the great leaves much used in thatching, and the fruit edible.

Trunks or rootstocks prostrate, gregarious: lvs. pinnatisect, 10–30 ft. long, from the ends of the rootstocks; lfts. numerous, rigid, plicate, lanceolate, long-acuminate, 2–3 ft. long: fls. monœcious, in an erect infl. springing from the rootstock; male fls. small, in catkin-like lateral branches of the spadix, stamens 3; female fls. larger, in terminal globose heads, the carpels 3: fr. large and spherical (as large as a man's head), comprised of many carpels or drupes 4–6 in. long. Toddy is extracted from the spadix, and from this product other materials (as sirup, sugar and vinegar) are made. Kernel hard and white, edible. *N. frùticans*, Wurmb., is a most useful plant in the thatch-making in the Philippines (Figs. 1993, 1994, Vol. III), but it is probably not cult. to any extent. It has been intro. in S. Fla.

L. H. B.

2483. Nolana paradoxa. (×½)

NIPHÆA (Greek, *niphos*, snow; alluding to the white color of the fls., which is not usual in this family). *Gesneràceæ*. Tropical American stemless or dwarf soft-villous herbs, with cordate, coarsely serrate lvs. and clusters of about a dozen fls. an inch or so across, borne singly on reddish stalks. For general cult. they are inferior to gloxinia and achimenes, but they are desirable for botanical collections. They have a creeping root, and no tubers: lvs. wrinkled, petiolate, opposite: corolla nearly wheel-shaped; disk absent; stamens 4 or 5; filaments short, straight; anthers erect, free, the cells facing inward, parallel, confluent at the apex.—Species 2, Guatemala and Cuba.

oblónga, Lindl. Height 1 ft.: lvs. heart-shaped or perhaps somewhat oblong, more or less whorled, petioled and cordate at base, strongly serrate, hirsute and rugose: fls. drooping, winter; corolla about 1½ in. across, pure white, on slender reddish peduncles; lobes roundish, concave at first, then revolute. Guatemala. B.R. 28:5. H.U. 5, p. 301.

L. H. B.

NIPHÓBOLUS. A name once in rather general use but now replaced by *Cyclophorus*, which see.

NITRÀRIA (Latin *nitrum*, natron; in reference to its habitat in nitrous soil). *Zygophyllàceæ*. Niterbush. Four low rigid shrubs distributed from S. Russia to Mongolia, W. China and Persia and through Asia Minor to Arabia and N. Afr., with alternate small fleshy, entire or dentate, stipulate lvs. and with small white or yellowish green fls. in terminal cymes followed by berry-like drupes: calyx 5-parted, fleshy; petals 5, concave; stamens 15; ovary superior, conic-oblong, attenuated into a very short style with 3 connivent stigmas, 2–6-celled: fr. an ovoid drupe with a sculptured 1-seeded stone dehiscent at the apex; cotyledons often 3. The following species is sometimes cult. in European botanic gardens and has been intro. recently by the Dept. of Agric. into this country and recommended as a sand-binder for cooler semi-arid regions; its fleshy fr. is edible. Prop. by seeds and by layers. It is of difficult cult. under ordinary conditions, as it is, like most desert plants, impatient of too much moisture and seedlings particularly are liable to damp off. It grows well in saline and alkaline soils; in ordinary soil an application of salt is recommended to grow it successfully.

Schòberi, Gmel. Spiny rigid shrub, to 6 ft., with whitish branches: lvs. obovate-oblong to linear-spatulate, obtuse or sometimes acutish, entire, thickish, silky while young, finally usually glabrous, ⅓–¾in. long: fls. white, about ⅓in. across, in stalked terminal cymes about 1 in. across; petals spatulate-oblong; stamens about as long as petals: fr. purple or blackish violet, rarely yellow, about ⅓in. long. June; fr. in Sept. and Oct. From S. Russia to Mongolia, W. China and Persia. L.B.C. 14:1395.—By the Dept. of Agric. the plant was intro. from Turkestan as *N. retusa*, but *N. retusa*, Aschers., is a native of Syria, Arabia and N. Afr. and easily distinguished by its broadly obovate lvs. usually 3-toothed at the apex.

Alfred Rehder.

NITROGEN. The rôle of nitrogen in horticulture is discussed under *Fertility, Fertilizers, Legumes, Lime* and *Manures*.

NOLÀNA (from *nola*, a little bell; referring to the shape of the corolla). *Nolanàceæ*. Prostrate annual herbs with showy blue flowers opening only in sunshine, valued chiefly for covering poor or rocky places.

Stem often slightly angulate, usually spotted and streaked with purple above glabrous or viscid-pubescent, much branched, the ends of the branches ascending several inches: lvs. solitary or in pairs, entire, usually fleshy, the lower long-petioled; the upper short-petioled, sessile or attenuated into a winged petiole: fls. borne singly in the axils of the lvs., mostly short-peduncled, commonly blue or purple, rarely white or rose; calyx 5-parted; corolla short funnel-shaped or bell-shaped, as in Convolvulus, entire, 5-angled or 5–10-lobed; ovaries 5 to many, 1–5-seeded, arranged in 1–2 series or clustered irregularly around the base of the style.—About 20 species, all native in Chile and Peru, mostly seacoast plants.

The characters by which several species of Nolana have been separated are not well defined. It is probable that *N. prostrata* and *N. paradoxa* should be considered as one species. The chief characters which have been used to distinguish them are the number of ovaries in each flower and the number of seeds in each ovary; but these characters vary in different plants of these and other species of Nolana.

Nolanas grow readily from seeds sown in the open in May. For early blooming and for seed-production they should be started under glass in March and transplanted in May. *N. paradoxa* is used with fine effect when planted in large patches in the border or on rocky hillsides. All of the species do well in pots. They prefer a light soil and sunny situation. *N. paradoxa* is well suited for use in vases and baskets.

A. *St. smooth or sparsely hairy.*

B. *Fls. large (1–2 in.), dark blue, not striped.*

paradóxa, Lindl. (*N. atriplicifòlia*, Hort.? *N. grandiflòra*, Lehm.). Fig. 2483. Seven to 10 in. tall: root-lvs. very long-petioled, ovate; st.-lvs. ovate, mostly sessile or with winged petiole, fleshy: fls. large, 1–2 in.; sepals ovate-lanceolate; limb of corolla blue; throat white, inside of tube light yellow; ovaries commonly many, 1-seeded. Chile. B.R. 865. Not B.M. 2604, which is *N. tenella.*—This is the most common species in cult. Var. **álba,** Hort., has white fls. Var. **violàcea,** Hort., has violet fls. F.S. 13:1294. H.F. II. 1:60.

BB. *Fls. small (¾in.), light blue, striped with dark purple.*

prostràta, Linn., not Hook. Resembles *N. paradoxa* but is distinguished by the st. being more reclining, the fl. is smaller and the throat of corolla marked with violet-purple veins: calyx pyramidal with triangular lobes: ovaries commonly few, 2–4-seeded. Perhaps this should be united with the preceding; it is native to Peru. B.M. 731.

AA. *St. densely hairy.*

B. *St.-lvs. lanceolate, thick: plant hoary-pubescent.*

lanceolàta, Miers. St.-lvs. rather narrow, mostly in pairs, 2–6 in. long, the base obliquely clasping or slightly decurrent on the outer side: sts. hairy: fls. 1–2 in. broad, with a spreading 5-lobed limb, each lobe deeply notched; limb of corolla azure-blue, throat yellowish white, marked at the base with a line of purplish blue and spotted yellowish green. Chile. B.M. 5327. H.F. II. 5:55.

BB. *St.-lvs. ovate, membranaceous: plant viscid-hairy.*

tenélla, Lindl. St. and whole plant viscid-hairy: st. slender: upper lvs. ovate, membranous, obtuse, with rounded base and winged petiole: peduncle long-hairy: fls. violet-blue, with a white throat; limb 5-lobed, each lobe tipped with a broad point. Chile. B.M. 2604 (erroneously as *N. paradoxa*, but poorly shown as no hairiness is indicated).—Not advertised in Amer.

S. W. Fletcher.
A. C. Hottes.†

NOLÌNA (C. P. Nolin, joint author of an essay on agriculture, Paris, 1755). *Liliàceæ*, tribe *Nolìneæ*. Sub-acaulescent, or small trees, with dracena-like leaves, little cultivated except under glass, and sometimes in open grounds in southern California and comparable regions.

The liliaceous tribe Nolineæ, in addition to Dasylirion, contains 3 genera with unarmed lvs., so closely related that they have been united by excellent botanists under the genus Nolina. As now limited, however, Nolina has panicled small polygamo-diœcious fls. and wingless 3-lobed 1–3-seeded often inflated fr.; Calibanus differs from it in the fr. being neither lobed nor inflated; Beaucarnea, like Dasylirion, has 3-winged fr., neither lobed nor inflated, and its trunk differs from that of Nolina in being more swollen at base. S. U. S. to Cent. Amer. Monograph in Proc. Amer. Phil. Soc. 50 (1911), by Trelease; species 24. Other species than those enumerated below may be expected in the collections of amateurs. Treatment in cult. as for yuccas.

2484. Beaucarnea guatemalensis.

longifòlia, Hemsl. (*Yúcca longifòlia*, Schult. *Y. Barrancasécca*, Pasquale. *Dasylírion longifòlium*, Zucc. *Roulínia Karwinskiàna*, Brongn. *Beaucárnea longifòlia*, Baker). Rough-barked small tree 5–10 ft. high, with somewhat swollen base and few short branches crowded at top: lvs. thin, green, rough-edged, more or less frayed at tip, 1 in. x 3 ft. or more, gracefully pendent: infl. nearly sessile; fls. $\frac{1}{16}$in. long: fr. ¼in. long, ½in. wide, inflated; seed roundish, ⅛in. diam. S. Mex. Abhandl. Akad. Muenchen. Cl. 2. 3:1. R.B. 1865:20; 31, p. 230. Gn. 24:433. G.C. II. 7:493, 567. Bull. Soc. Ort. Tosc. 1890:6. G.W. 11, p. 14; 14, p. 199. G.Z. 3:20. Natur, 34:340. Gt. 29:117; 33:68. R.H. 1911, p. 206. Proc. Amer. Phil. Soc. 50:3, 8, 13, and p. 426.

The following species are given the nomenclature under Beaucarnea:

B. recurvàta, Lem. (*B. tuberculàta*, Roezl, *Nolìna recurvàta*, Hemsl. *N. tuberculàta*, Hort. *Pincenectítia tuberculàta*, Lem.). Becoming 30 ft. high, slender-branched above, swollen at base: lvs. green, thin, smooth-edged, recurving, ¾in. x 3–6 ft.: infl. nearly sessile; fls. $\frac{1}{16}$in. long: fr. unknown. S. E. Mex. I. H. 8, p. 58. G.C. 1870:1445; III. 46:4. D.G. Mag. 1871:288. Gt. 28:210. Gn. 19, p. 372. R.H. 1911, p. 207.—Tender in Cent. Fla.

B. guatemalénsis, Rose. Fig. 2484. Slender, sometimes much-branched tree, 20 ft. high: lvs. green, thin, smooth-edged, recurving, 1 in. x 3 ft.: infl. short-stalked; fls. ⅛in. long: fr. ½ x ⅝in. Guatemala. Contr. U. S. Nat. Herb. 10, p. 88.—Tender in Cent. Fla.

B. strícta, Lem. (*B. recurvàta strícta*, Baker. *B. glaùca*, Roezl. *B. Purpùsi*, Rose. *Pincenectítia glaùca*, Lem.). Becoming 30 ft. high, somewhat branched: lvs. pale, slightly rough-edged, straight, ¼–½ in. x 2–3 ft.: infl. short-stalked; fls. $\frac{1}{16}$in. long: fr. ¼ x ½in. S. Mex. D.G. Zeit. 28:223. Proc. Amer. Phil. Soc. 50:8, 14.

B. grácilis, Lem. (*B. oèdipus*, Rose. *Nolìna hístrix*, Hort.). Becoming 30 ft. high, greatly swollen at base variously branched: lvs. very glaucous, rough-edged, straight, ¼ x 18–20 in.: infl. short-stalked; fls. $\frac{1}{16}$in.

long: fr. ⅜in. long and broad. S. Mex. Contr. U. S. Nat. Herb. 10:23. Publ. Carnegie Inst. No. 99:19. Proc. Amer. Phil. Soc. 50: 4, 11.

N. Hartwegiàna, of gardens—but not the species properly so-called—a plant with round rough-barked st. about as large as a coconut and narrowly linear tufted lvs., is the type of a related genus, Calibanus, which differs in its rounded 3-celled fr. neither inflated, lobed nor winged, and is known as *Calibànus Hoòkerii*, Trel. (C. cæspitosus, Rose. Dasylirion Hookerii and D. Hookeri, Lem. D. cæspitosum Scheidw. D. flexile, Koch. Beaucarnea Hookeri, Baker). E. Cent. Mex. B. M. 5099. Contr. U. S. Nat. Herb. 10:24, 25, and p. 90, fig. 4. Proc. Amer. Phil. Soc. 50:6, 8, 9, 11, 14.—The most beautiful of all this group is *N. longifolia*, when young, with its crown of drooping leaves 6 feet or more long, reaching to the ground. Few other true nolinas possess much beauty, but the caulescent species are odd and rather graceful, and Lower Californian forms like *N. Bigelovii*, Wats., *N. Beldingii*, Brandegee (G.C. III. 34:43) and *N. Parryi*, Wats., may succeed in the warmer parts of California.

William Trelease.

NÓLTEA (after E. F. Nolte, professor of botany at Kiel; born 1791). *Rhamnàceæ.* Soapbush. An evergreen glabrous shrub from S. Afr., with alternate short-petioled serrate lvs., small deciduous stipules and with small white polygamous fls. in terminal and axillary panicles: calyx campanulate, 5-lobed; petals 5, small, shorter than sepals, cucullate; the 5 stamens opposite the petals; ovary half-inferior, 3-celled; style rather short, with slightly 3-lobed stigma: fr. a caps., 3-valved, septicidal with 3 erect compressed seeds. The whole plant is saponaceous and the macerated foliage is used by the natives in washing. Sometimes used as a hedge plant in S. Afr. Cult. occasionally in S. Calif., though it has scarcely any particular ornamental quality. Prop. is by hardwood or greenwood cuttings and also by seeds. **N. africàna,** Reichb. (*Ceanòthus africànus*, Linn.). Upright shrub with virgate branches, to 12 ft.: lvs. oblong-lanceolate, serrate, obtuse, pale green below, 1–2 in. long; stipules small, roundish, thickish: fls. whitish, ⅙in. across in short axillary and terminal panicles crowded at the end of the branches into leafy panicles several inches long: caps. ⅙in. across. S. Afr. Sim, Forests and For. Fl. Cape of Good Hope, 37.

Alfred Rehder.

NOPÀLEA (from the Mexican name of the cochineal cactus). *Cactàceæ.* A genus of 4 or 5 species, often placed with the opuntias, but differing from the latter in having erect petals, and stamens and style exsert beyond the perianth, as well as in some minor details. Natives of Trop. Amer. **N. coccinellífera,** Salm-Dyck (*N. inapérta*, Schott). An arborescent, flat-stemmed plant, with a somewhat cylindrical trunk 6–10 in. diam., widely grown in semi-tropical countries, but rarely found in the U. S., and then only in the largest collections of cacti. It is chiefly interesting in being one of the important food-plants of the cochineal insect. B.M. 2741, 2742 (as *Cactus cochinellifer*). *N. guatemalénsis* and *N. lùtea* are 2 recently described species from Guatemala which have been intro. into cult.

J. N. Rose.

NORÒNHIA (after Ferd. de Noronha, Spanish naturalist and traveler: died 1787). *Oleàceæ.* One tree or large bush, differing from Olea in having separate petals and in other characters. *N. emarginàta*, Poir. (*Òlea emarginàta*, Lam.), is native in Madagascar and other islands, and is planted somewhat in Hawaii. Lvs. opposite, evergreen, short-stalked, coriaceous, cuneate-oblong and more or less retuse, entire: fls. yellowish, fragrant, in axillary clusters; calyx small, 4-toothed or -cut; petals 4, sometimes somewhat coherent at base: fr. an edible drupe, purple when ripe, globular, about 1 in. diam.; seed usually 1 (ovary 2-celled), in the sweet pulp.

NORTH AMERICAN STATES, Horticulture in. The descriptive articles on the horticultural resources of the North American continent are comprised in two parts: the symposium on British North America in Volume I, and the present assembly. These together give a comprehensive view, and yet in some detail, of the present state of development in fruit-growing, vegetable-growing, flower-growing, and related activities in this vast area. Inasmuch as the statistical information is not comparable as between the British and the American parts of the continent, and as the markets and governmental control are different, as well as for other reasons, it has seemed best to treat the two parts separately, although the reader will want to consult them both to secure his view of the continent as a whole.

The article on Alaska naturally attaches itself to the present account. It is desirable, also, to present here an account of the horticultural possibilities of the Canal Zone (with its ten-mile strip across the Isthmus of Panama), although that region is not correctly a part of North America; but it belongs with the same governmental administration as the continental states of the Union, and the trade relations will naturally be close.

A third group of descriptive articles is found in Volume III, under the title "Island Dependencies." These insular areas are all tropical and therefore have a more or less common interest. The islands are Porto Rico, page 1689; Hawaii, page 1692; Guam, page 1696; Tutuila, page 1699; Philippines, page 1702.

In percentage of total value of all crops in the United States, the horticultural products reach not more than 13 per cent, even counting potatoes and sweet potatoes as within the definition. The census figures for the year 1909 give the percentage of value of vegetables (including potatoes, sweet potatoes and yams, and other vegetables) to be 7.6 per cent of the total value of all crops; of fruits and nuts to be 4 per cent; of flowers and plants to be .6 per cent; of nursery products to be .4 per cent. In average value to the acre in 1909, "flowers and plants" lead all crops, with $1,911.02; small-fruits $110.01 to the acre; potatoes, $45.36; sweet potatoes and yams, $55.25; "other vegetables," $78.26. This may be compared with the acre-value of staple field crops, as cereals $13.93; hay and forage, $11.40; tobacco, $80.55; cotton (including seed), $25.74; sugar-beets, $54.60; sugar-canes, $55.40.

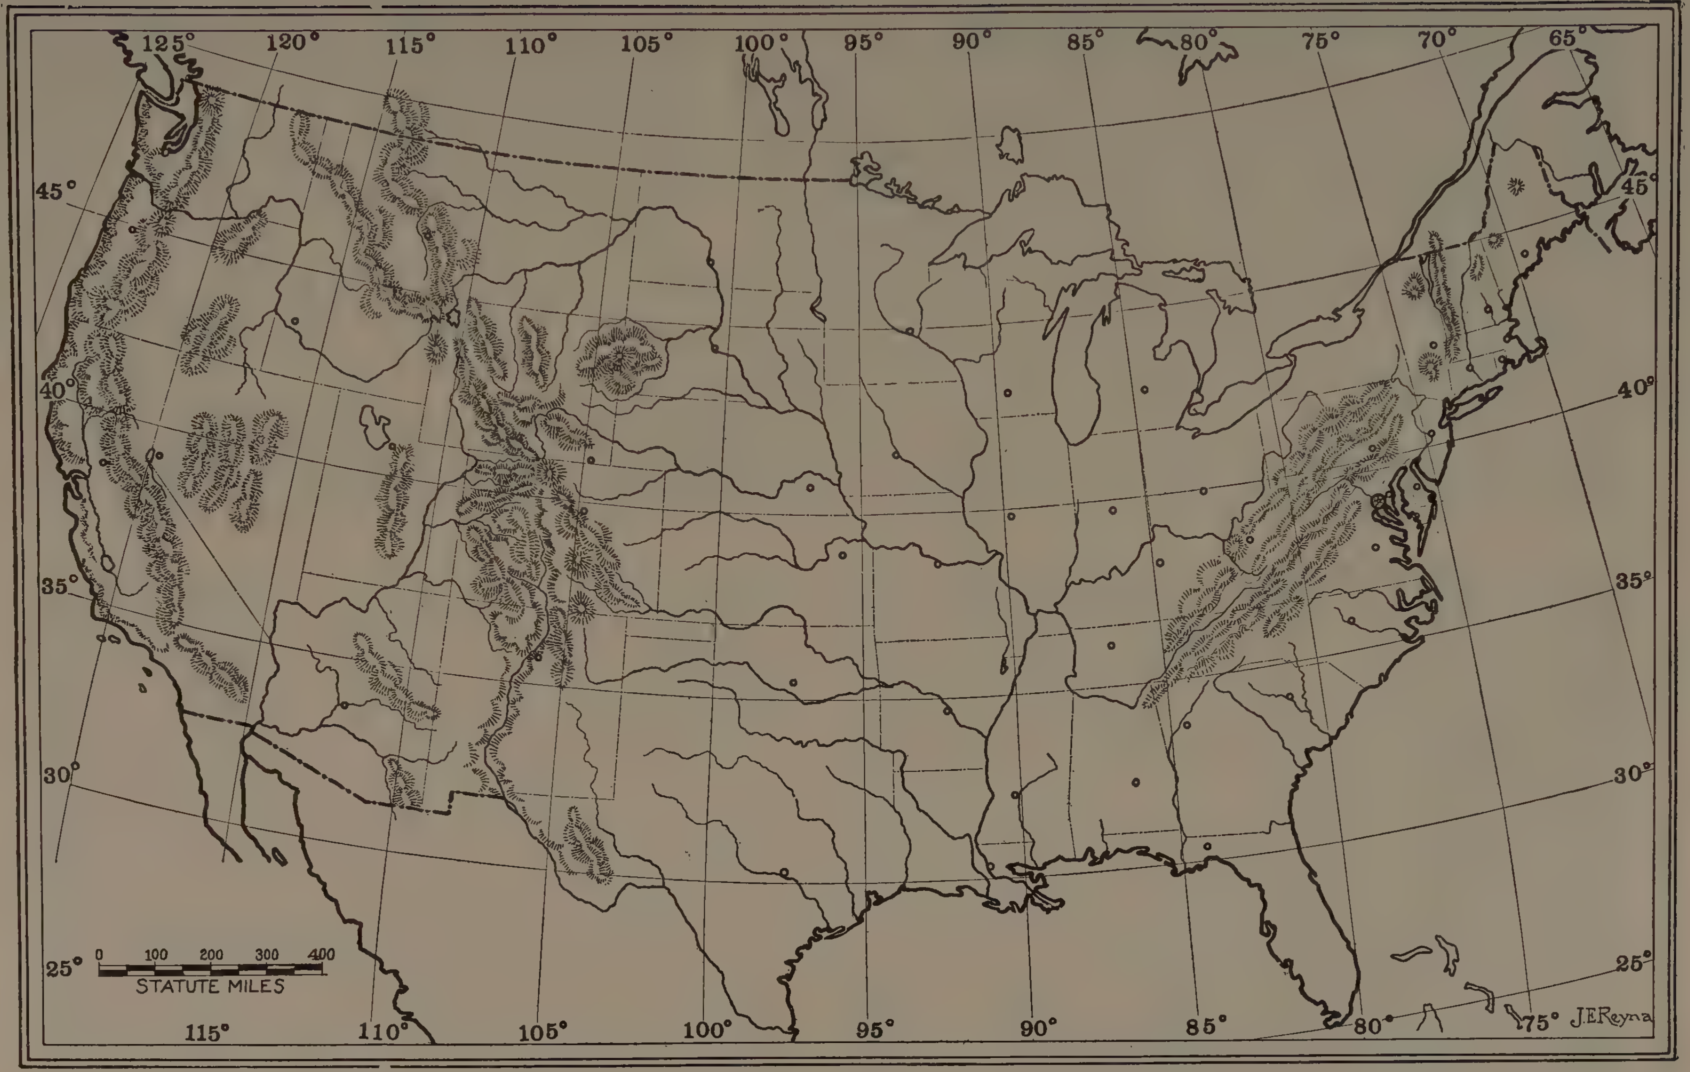
The territory of the continental United States comprises practically the whole range of climate. While none of it is within the tropics, the southern end of Florida is essentially tropical; the Gulf coast, southern Texas, southern California and the less elevated regions between are subtropical; and Alaska is partly within the arctic. There are long ranges of seacoast climates, and vast areas of midcontinental conditions. There are regions of unusually heavy rainfall, and others of very deficient precipitation and with desert conditions. There are widely different drainage systems, elevations from perpetual snow to depressions below sea-level, and the widest variations in soils and exposures. These wide ranges of conditions provide the physical basis for the most diverse horticultural pursuits. The mountain barriers and main drainage basins, as well as the seacoasts, are shown in Fig. 2485. This map may be joined to that of the British possessions, Fig. 652, on page 560.

The present symposium on the horticulture of the United States takes the form of an account by states; and these states are assembled in groups to represent geographical regions, as follows:

New England States.—Maine, page 2152; New Hampshire, page 2154; Vermont, page 2157; Massachusetts, page 2159; Rhode Island, page 2162; Connecticut, page 2164.

Middle Atlantic States.—New York, page 2167; New Jersey, page 2170; Pennsylvania, page 2173.

East North Central States.—Ohio, page 2176; Indiana, page 2179; Illinois, page 2182; Michigan, page 2184; Wisconsin, page 2187.



2485. Outline map of the United States, showing great drainage basins and some of the mountain masses.

West North Central States.—Minnesota, page 2190; Iowa, page 2193; Missouri, page 2196; North Dakota, page 2199; South Dakota, page 2202; Nebraska, page 2205; Kansas, page 2207.

South Atlantic States.—Delaware, page 2210; Maryland, page 2212; Virginia, page 2215; West Virginia, page 2218; North Carolina, page 2220; South Carolina, page 2223; Georgia, page 2226; Florida, page 2229.

East South Central States.—Kentucky, page 2232; Tennessee, page 2235; Alabama, page 2237; Mississippi, page 2240.

West South Central States.—Arkansas, page 2243; Louisiana, page 2246; Oklahoma, page 2249; Texas, page 2251.

Mountain States.—Montana, page 2255; Idaho, page 2257; Wyoming, page 2260; Colorado, page 2263; New Mexico, page 2266; Arizona, page 2269; Utah, page 2272; Nevada, page 2275.

Pacific States.—Washington, page 2278; Oregon, page 2281; California, page 2284.

Alaska, page 2287.

The statistics concluding the articles, compiled by Editor, are taken from the Thirteenth Census, 1910 (products of 1909). This is with the purpose not only to give the statistics of each state but to afford a basis of comparison between the states and to present the facts for the Union. As a basis of comparison, the main agricultural products are also given. The categories of fruits are those used in the Census classifications. It does not necessarily follow that "peaches and nectarines" means that there are nectarines growing in commercial quantities in the given state, or that loganberries are grown when the category is "raspberries and loganberries." In some cases in which these and other incidental fruits are known not to be grown, the names have been eliminated, but not always so. The statements are classificatory.

The Canal Zone (Fig. 2486).

When Balboa followed the narrow jungle trails of the Indians from one rambling settlement to another across the Isthmus, he probably noted, if he took any horticultural notes at all, that the economic flora was deplorably meager. The palm-thatched "bohios," as they called their one-room dwellings, were scattered along the high banks of the rivers, just above flood-mark; and the patches of root-crops and grains were massed close up under the watchful eye and ear of the planter,—to avoid depredations by the plentiful game animals, the deer, tapirs, agoutis, pacas, and their kind. This sort of make-believe horticulture, however, had been improving very slowly for thousands of years when the first Spaniard appeared on the scene.

If we hold, with O. F. Cook, that the first ideas of agriculture originated in the old Caribbean region, if we place the birth of the science back to the first purposeful covering of an otó tuber in a half-cleared plat somewhere about here some 50,000 years ago, then we must needs offer some explanation for the undeniable backwardness of tropical American horticulture at the beginning of the sixteenth century. We may rightly ignore all ethnological points in the case and assert that in this region a little more than anywhere else on the earth's surface did the food-plant growers have a pitiably laborious and precarious struggle with the primeval jungle. Indeed, it is doubtful whether even the present inhabitants of the Chagres Valley could eke out enough to live on from their little semi-cultivated patches if they were deprived of the machete and their few other "civilized inventions."

In point of fact, however, the indigenes of this region had a fairly large number of quasi-economics in use, not to say in cultivation. They probably depended upon the larger game animals to a great extent, with fish, snakes, and iguanas also *en mênu;* their main root-crop was "yuca," or cassava (*Manihot dulcis* var. *Aipi, M. utilissima*), and to this day the "small farmer" of the interior of the Isthmus sets great store on "farina," the artificially dried, grated, peeled root. Otó, or Yautia (Xanthosoma spp.) was probably second in importance as a vegetable food and undoubtedly existed then in many forms. Of yams there were probably several species, all inferior to those now in evidence. The malanga, or taro (Colocasia), probably arrived with the Spaniards. The sweet potato may have been in evidence, but the present dialects of the Panamanian Indians (according to Pittier) contain no word for this root. And the "cacahuate," or peanut, was a prominent prehistoric crop from Mexico to Peru.

Among the fruits, the avocado, indigenous from Peru to Mexico (but not in the West Indies), demonstrates its nativeness by attaining a greater size here than elsewhere—2 feet in diameter, with a height of 65 feet or more, and fruits in proportion; the Mexican black-skinned and the Guatemalan hard-skinned varieties are unfortunately absent. The cashew (*Anacardium occidentale*) is and probably was common everywhere outside of the forests; the sister species, the espavé (*A. rhinocarpus*) is a conspicuous jungle giant. The guavas, though unable to compete with the forest species, are among the first to occupy cleared ground. The annonas were probably common; three forest species bear edible fruit. Two caimitos, or star-apples (Chrysophyllum spp.) are half or wholly wild. The calabash (*Crescentia Cujete*) was probably semi-cultivated for the sake of its fruit-rinds, used in lieu of crockery.

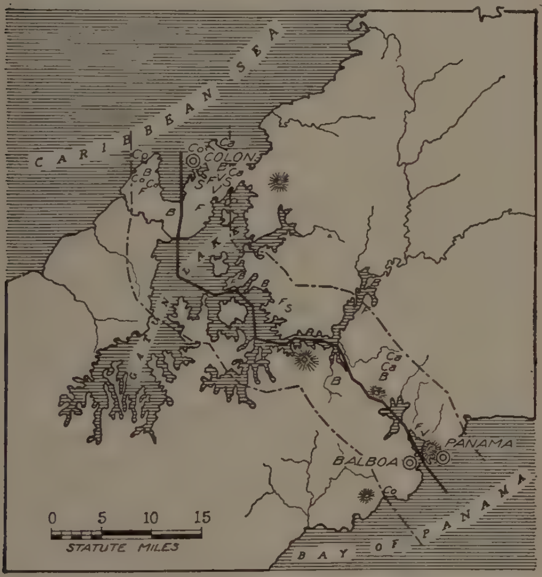
The pineapple probably made its first appearance to the public somewhere in this region. As to the bananas and plantains, it will probably never be known just how or when they were introduced (from Africa or, more probably, from the Orient); it seems certain, however, that there were a few varieties (out of the 300 or more) under cultivation when Balboa came. The anotto (*Bixa Orellana*) was doubtless used then, as now, for decorating the body and, mixed with palm-oil, to keep away mosquitos and the terrible "sand-flies" and ticks.

There were probably also peppers, ginger, papayas, maize, and beans in those plantations of 4,000 years ago; but unlike their distant neighbors, the Incas and Aztecs, the Isthmian planters neglected to set it down on stone records.

The first two centuries of civilization brought but little to this region in the way of new economic plants; but as soon as travel across the Isthmus became a real movement, and with pirates and brigands becoming unpopular, Panama horticulture began to improve. The Indian mango and the Polynesian bread-fruit arrived and soon assumed a permanent predominance over all other fruits, except the avocado and the musas. The citrous fruits, various vegetables, rice, sugar-cane, the akee (brought in with the slaves) and, of course, the ubiquitous tropical ornamentals (Aralia, Hibiscus, Acalypha, Codiæum, Jasminum, and others) came in due time. Many first-class economics, however, such as sapodillas, star-apples, sweetsops, tamarinds, mammee apples, and mammee sapotas, are still nearly or quite absent within the Zone boundaries. The French brought in a few good things. In 1906 to 1908, H. F. Schultz, as horticulturist, began the propagation of ornamentals and vegetables; through the auspices of David Fairchild and the writer, a good collection of economics was sent from the propagating-houses of the United States Department of Agriculture, at Washington, D. C., to the Zone, with partial success. About 1908–9, it was considered impracticable to raise fresh vegetables and fruits for the Canal Commissary, and until the native plantations began to be "bought in" by the Land Office, January 1, 1913 (by Presidential Order of December 5, 1912), Zone horticulture was in a state of desuetude. Oranges, bananas, avocados, and the like, were sometimes gathered wherever it seemed expedient, without a definite policy of management, till October, 1914.

At present (1915), even, it is uncertain how far the Supply Department is warranted in going with the upkeep of the hundreds of small and large plantations expropriated from the Panamanian and West Indian settlers, and how many new plantations are actually required, first, in the interest of financial economy, and, second, as a safeguard measure: i.e., a meat, fruit and vegetable supply *in loco* in case of a sudden isolation of the Zone. (In fiscal year ended June 30, 1914, the Land Office settled 1,903 claims of squatters, aggregating $147,452.50).

Corregidor Island, at the entrance to Manila Bay, according to report, has enough food-supplies in store in dry and refrigerated vaults to last the entire American population of the archipelago for more than one year; a week's blockade of the Canal Zone would, under present conditions, cause considerable trouble, and three weeks with no commissary stock from oversea might be disastrous, since the contiguous Panama territory could supply only the cities of Colon and Panama, and then only a few things. Theoretically, nearly all the food required by the 30,000 or more employees and their families, who are almost entirely dependent upon the Supply Department for their daily food, may be produced in the Zone; practically, however, the daily quotum of 92 to 108 barrels of flour, about 285 bushels of potatoes, and the temperate fruits and some of the vegetables in like proportion, will always have to be imported.



2486. The Canal Zone. *B,* Bananas; *Ca,* Cacao; *Co,* Coconuts; *F,* Fruits; *S,* Sugar-cane; *V,* Vegetables.

At the beginning of 1915, there were practically no vegetables or fruits (except bananas and plantains) raised in the Zone, with the exception of a square mile or more of native fields near Colon which have not yet been expropriated, and the Hospital Farm at Corozal; the latter institution produces fresh eggs, milk, and a fair supply of radishes, okra, lettuce, papayas, and other things for Ancon Hospital.

At Las Guacas, 12 miles up the Chagres River from the lake,—i. e., some 6 miles beyond the east boundary of the Zone, but below the "100-foot level" (land along water-courses leading into the lake, up to 13 feet above its mean water-level is also by treaty included in Zone territory)—there are two small banana and plantain "walks," which, when fully under cultivation, will turn out not only all of these fruits required by the local commissary stores, but will also supply, nearly at cost, all the steamers in port and in transit through the Canal, a very considerable demand.

At Juan Mina, also on the Chagres, just within the Zone limits, a citrous grove is now being established; with water transportation (forty minutes by launch to Gamboa railway station), good soil, and phenological suitability, as demonstrated by the few scores of very prolific native orange (seedling, of course) trees now in evidence there, it is thought that by 1918 or 1919 the absurd necessity of importing thousands of dollars' worth of pomelos, oranges, mandarins, limes, and other fruits from Florida, Costa Rica and Jamaica will be absolutely and permanently removed.

At Chocolate (formerly the Las Cascadas Plantation Co., Ltd., a British-capital concern), on the continental divide 5 miles from Culebra Cut, over six tons of dry cacao "beans" from only about 15,000 trees in "run-down" condition have been turned out in the first ten weeks of operation by the Supply Department. This estate boasts of having the oldest Castilla trees, planted as a crop, in the world. The unfortunate Castilla boom actually started, it is said, from these now 30-centimeter to 40-centimeter, moribund, worthless specimens, and an optimistic German scientist who happened to come by a dozen years or so since. The semi-abandoned cacao trees here broke the world's record, perhaps, for rapid maturing of the year end crop; six heavy pickings had to be made the first six weeks, instead of the two or three normal ones.

A grove of over 500 avocado seedlings, one of the largest in the world, has been set out at Frijoles; and mangoes, citrous fruits, pineapples, yams, sweet potatoes, and maize (for table ears) are going in, bananas and sugar-cane are also in evidence.

At Manawá and Puerto Escondido ("Condio," in local dialect), two native villages some 3 miles to the east of Colon, there are endless problems for the investigating horticulturist;—from major crops, like sugar-cane and cacao, through hundreds of acres of half-tilled patches of bananas, yams, and cassava, to fussy little questions of economy regarding the rejection or retention of small lots of coconuts, bread-fruits, avocados, limes, roselle, guavas, native squashes, ginger, and even cola.

At Venado, there are 20,000 non-bearing coconuts mostly in good condition. This plantation, if kept up under modern methods, will yield annually by 1925 sufficient oil to make some 300 tons of soap, enough to last the War Department a long time. At Sweetwater, there are several thousand coconuts in bearing, but in heavy bush and consequently in unprolific condition. In all there are twelve plantations now under some form of management by the Chief Quartermaster's Supply Department; the condition of these will be improved as rapidly as circumstances will permit; some may be extended, and a few more will probably be added.

As to the jungle: near the Canal there is no virgin forest left intact and, in fact, the better timbers have been culled out all along the Panama Railroad. The forest within sight of the steamers and trains is mostly second growth; this, however, is usually more dense than the old stand. Here is an opportunity for the Government to practise modern forestry and develop, say, 100 square miles of timber reserve.

As everywhere in Central America and the West Indies, the silver-lined leaves of the trumpet-wood (Cecropia) and the crumpled leaves of the also ugly companion Didymopanax are ever before the eye, just as some one of the four or five Heliconias is always in the way. Numerous Bombaceæ are to be found in or around every forest area; their interesting bolls, if one may so term them, are as remarkable as their trunks; the trunk of one, *Bombax Barrigon*, is true to its vulgar Spanish specific name, in having a very "aldermanic rotundity" just above its base. The lofty but proportionately small crowns of the giant "Cuipo" (Cavanillesia) are a feature of the landscape near Pedro Miguel, which happens to be about the northernmost limit of this striking South American tree. There are, as everywhere in the tropics, many Ficus species, to puzzle future botanists. Mahogany and cedar are scarce, except near the Zone limits; however, the cutters' axes of a concessionnaire can be heard from the orange plantation at Juan Mina. Some new Lecythaceæ have recently been discovered by Pittier of the United States Department of Agriculture; some of the nuts rival the Brazil and Paradise nuts. Many excellent hardwoods are also in evidence.

The branches and trunks of the rough-barked trees usually support a varied flora of bromeliads, aroids, and orchids. On the Atlantic slope, where the rainfall averages around 125 inches a year, the orchids revel in a droughtless climate; the dry season—December to April, or longer—of the south or so-called west side of the Isthmus, the precipitation of which is just about one-half that of the Colon region, makes for a different flora. The most famous orchid here is the "Holy Ghost," or "Dove" (*Peristeria elata*); a coryanthes is more interesting, however, and makes up in number of flowers what they lack in size as compared with its bizarre sister species, *C. macrantha* of the Trinidad "high bush." The deep purple sobralias are striking; the butterfly orchids (Oncidium spp.) are everywhere, and range from buttonhole size (meaning the entire plant with its two bright yellow flowers) to the one with an 8-foot peduncle.

Several fine marantas and costus spp. and rank Zingiberaceæ and Araceæ encumber the ground wherever they can find plenty of shade and moisture. The carludovicas, that made Ecuador hats world-famous, abound in the denser jungles and are one of the worst sorts of weeds on the Manawá cacao plantations; in one ravine the petioles attain a length of 6 meters (20 feet)! Tagua (Phytelephas sp.) barely enters the Zone from the south. But the true palms are everywhere: Acrocomia, Attalea, Bactris, Elæis, Iriartea, Hyospathe, even the terrible desmoncus (worse than the calamus of the Philippines). Four species, at least, yield oil for the native table and two might prove of commercial importance, the corozo (Acrocomia) and the elæis, for their kernels. Nuts of a small-fruited species of Attalea, the commonest large forest palm, may also through their great abundance be of value.

Most of the still-water reaches of the "3,000-mile coast-line" of Gatun Lake are more or less filled with luxuriant water lettuce and lesser evils in the way of aquatics; the Dredging Division is only now getting the two water hyacinths under control, after a strenuous fight with arsenical sprays by the hundred barrels. The shallow bays teem with micro-organisms; the many square miles of submerged forest furnish an excessive amount of decaying vegetable matter to feed the subaquatic life; billions of fish-fry are appearing now,—so thick in places that they may be scooped out with the hand. Pará grass and a papyrus-like rush are preëmpting the margin—an ideal habitat for the hippopotamus, which should be introduced as a margin-mower and aquatic-consumer to help out the Health Department in destroying mosquito breeding-grounds, and incidentally to furnish the Supply Department with the same kind of wholesome meat that South Africa once depended on.

In a word, then, here in the most important country of its size in the world, the Panama Canal is meeting an unprecedented problem: in 325 square miles of moderately suitable territory, more or less isolated, how nearly self-supporting shall this area be made,—what sort of horticultural development should it have, and how much? The foreground is somewhat out of focus at present, but there are certainly some very interesting possibilities in the perspective.

O. W. Barrett.

NEW ENGLAND STATES.

Maine.

Maine (Fig. 2487), the most easterly state in the Union, lies between latitude 43° 6′ and 47° 27′ north, and longitude 66° 56′ and 71° 26′ west. It has a very irregular coast-line, extending from Kittery on the south to Eastport on the extreme east, so broken by river and bay indentations as to measure about 2,500 miles in extent. About one-tenth of the area of Maine is water. There are about 2,200 lakes and ponds which act as reservoirs to hold in reserve the vast water-power of the state. It has three large river systems extending well into the interior, along whose courses are found the most fertile farms in the state. A central elevated plain extends across the state from west to east, at an elevation of 1,000 to 2,000 feet, near the center of which is Mount Katahdin, which has an altitude of 5,385 feet. A considerable part of the five most northern counties of the state are still covered with a heavy forest growth. In the northwestern section, this consists of pine, spruce, fir, hemlock and cedar; while farther south the conifers are replaced by birch, beech, oak, ash, maple, and the like. About three-fourths of the land area is classed as forest land. Maine ranks first among the states in its annual cut of spruce and fir, and third in white pine and birch. The annual cut of all timber is about 1,000,000,000 feet. The forest interests of the state are separated into two classes, viz., the Maine forest district of about 9,500,000 acres, and the forested area of towns and plantations of 4,500,000 acres.

A large part of the state is especially adapted to the growing of fruit of exceptionally high quality. It is true that the fruit-growing industry in Maine is in its infancy so far as modern methods are concerned. Local conditions are such that the most favorable opportunities exist for the development of this industry. Portland is one of the most convenient ports for the shipping of apples to foreign markets, and large quantities are sent each year. The natural fruit-belt of the state embraces the section south of latitude 44° 30′, although some fine orchards are found in the center of the state extended to latitude 45° 10′. Latitude 45° north is regarded as the northern limit of profitable fruit-production, yet even in Aroostook County many orchards are yielding good returns, especially of such varieties as the Wealthy, Fameuse and Dudley Winter. The leading commercial fruit is the apple, the normal crop being about 1,000,000 barrels. The leading counties in the state in apple-production are Oxford, Cumberland, Androscoggin, Kennebec, Waldo and southern Franklin, Somerset, Piscataquis and Penobscot.

In York County, thrifty apple trees, over one hundred years old, are still bearing. These probably came from the famous Vaughan Nursery, in Hallowell, which was established about 1800. The Bowman Brothers, of Sidney, conducted an extensive nursery for a number of years, growing their stock from seeds taken from apple pomace at the cider-mill. The seedling trees were grafted to Baldwins, Rhode Island Greenings, Spy and other leading varieties. Remnants of the orchards set from this stock are still to be found in almost every section of the state. Many old seedling orchards, which yielded the once-famous "hard cider" for the Andrew Jackson political campaign, are still in existence, but these are rapidly passing with the coming of the movement for better fruit, and their places are being filled with the best commercial varieties. In 1910, about 1,000,000 apple trees were set. This was probably the largest number ever planted in one year. There are four leading nurseries selling fruit stock, but only two that make a business of budding their own stock on to French seedlings. Many orchardists are top-working over their Ben Davis trees to such varieties as Baldwin, Spy, Rhode Island Greening, while Delicious and Opalescent are gaining favor.

The following varieties of apples originated in the state: Wealthy, from seed obtained in Bangor in 1860; Rolfe, in town of Guilford, about 1820; Starkey, in North Vassalboro; Dudley Winter, seedling of Oldenburg, originated at Castle Hill, Aroostook County; Winthrop Greening, Winthrop, about 1800; Quince, at Cornish, about 1850; Parlin, Norridgewock, about 1840; Stowe, Perham, Aroostook County, 1862, and Hayford Sweet, at Maysville, Aroostook County.

Fine peaches are grown in Oxford and Androscoggin counties, in the southwestern part of the state.

Fifty years ago large quantities of the finest Black Oxheart cherries were grown and shipped from Hallowell in Kennebec County, but the orchards have become neglected so that but few old trees remain.

Plums, pears, sour cherries and grapes are grown throughout the southern half of the state, as far north as latitude 45°.

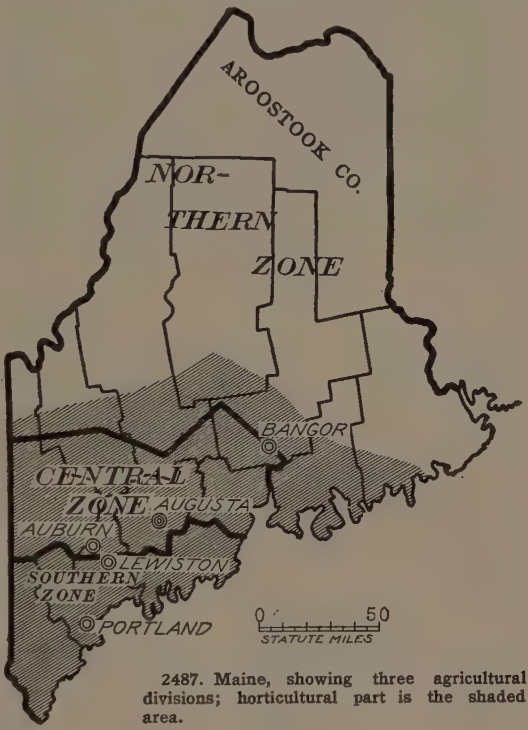
Small-fruits of all kinds grow wild in lavish abundance, especially strawberries, raspberries, blackberries, blueberries and cranberries. For cultivated berries, strawberries easily take the lead and are grown very extensively for local markets and to ship to Boston. The small-fruit industry is a profitable one and is being extended each year. The conditions are ideal, as the fruit comes on the market after fruits from other states have disappeared, thus bringing good prices with a large market demand. In Washington County is a large tract of about 150,000 acres, called the "Blueberry Barrens," which brings in a big revenue to the owners. Several thousand bushels of the berries are sold as fresh fruit, but the large bulk goes to the canning industry, yielding an income of several hundred thousand dollars. Cranberries are found to some extent along the coast and also in inland sections.

Potatoes stand second in crop-production. The starch industry is an important one for Aroostook County, yielding in 1914 about 20,000,000 pounds. Aroostook County far exceeds any other county in the United States in potato-production. There is a larger output from this county than from all the other counties in the state combined. The leading varieties are the Green Mountain and Irish Cobbler, although a large number of other varieties are grown. Under trial tests over 700 bushels have been grown on an acre; six-acre lots have given an average of 460 bushels; ten-acre lots, 350 bushels. Farmers who adopt up-to-date methods average 300 bushels an acre. This can be done in any part of the state. The town of Presque Isle, the garden of Aroostook County, has potato farms valued at $40,000. Contracts are made with growers in the southern states to supply Aroostook-grown potatoes for seed at $1 a bushel for a term of five or ten years. The variety most grown for this purpose is the Irish Cobbler.

The leading vegetables grown, as market-garden produce, include snap beans, beets, cabbage, cucumbers, lettuce, peas, squash, sweet corn and tomatoes. Of the above crops, large quantities of beans, corn, peas and squash are used in the canning industry of the state. Although Cape Elizabeth is the leading market-garden center, there are many other sections largely engaged in this industry, notably the towns around Lewiston and Auburn in Androscoggin County; Saco and Biddeford in York County; Augusta and Waterville in Kennebec County; Bangor in Penobscot County, and Elsworth and Mt. Desert, in Hancock County. Maine offers great inducement for market-gardening, cheap lands are available, fine shipping facilities are offered, both by boat and train, while electric lines are being extended so as to reach and open up large areas not previously available.

The first regular Maine nursery was probably located in the town of Orrington, then a part of Buckstown, between 1804 and 1812, by Ephraim Goodale.

Among those who were influential in the development of Maine horticulture may be mentioned the following: Benjamin and Charles Vaughan, pioneer nurserymen; Ezekial Holmes, the "Father of Aroostook;" Z. A. Gilbert; S. L. Goodale, nurseryman at Saco; D. H. Knowlton, authority on fruits; W. M. Munson, professor of horticulture; Phineas Whittier, the "apple king of Maine;" H. L. Deland, fruit-grower; James Nutting, fruit-grower; Captain Elijah Low, plum-grower; G. B. Sawyer, one of the pioneers for better fruit in Maine; E. K. Whitney, expert at grafting; Solon Chase, "the Spy king;" Frederick Hobbs, grape specialist.



2487. Maine, showing three agricultural divisions; horticultural part is the shaded area.

Public-service agencies for horticulture

The first agricultural school in the United States was established in Gardiner, Maine, in 1821, called the "Gardiner Lyceum." This institution flourished until state aid was withdrawn in 1835.

The land-grant college was established in Orono in 1864 as "The State College of Agriculture and Mechanic Arts." The name was changed in 1897 to the "University of Maine." There are three members of the horticultural staff.

The Experiment Station was established in 1885 as a department of the University. The state owns two experimental farms, one situated in the town of Monmouth in Kennebec County, used particularly for work with apples, corn, and small grains. The other is situated in the town of Presque Isle, in Aroostook County, used especially for studies with potatoes, small grains and grasses. These are under the supervision of the Experiment Station. The staff of the Experiment

Station is a strong factor in the line of horticultural progress in the state, especially in plant-breeding, with such crops as potatoes, corn, oats, beans and fruits; plant pathology, rendering great aid in identifying plant diseases and giving directions for their control; entomology, where expert advice is given, by means of bulletins on insect pests of the farm, garden and orchard.

About fifteen of the secondary schools in the state are offering courses in horticulture.

The State Department of Agriculture at Augusta has charge of all the nursery inspection work of the state and also holds orchard demonstrations.

The Extension Department of the University was organized in 1907, and work is now being carried on in nine out of the sixteen counties. Farmers' institutes are also held by the Department of Agriculture.

The Maine State Pomological Society was organized in 1873 and has had a great influence on the horticulture of the state. There are nine local fruit-growers' associations which are doing good work for better fruit for Maine. The Maine Seed Improvement Association was organized in 1910. The Gardeners' Union of Lewiston and Auburn was organized in 1914 to promote horticultural interests. The Maine State Florists' Society was organized in March, 1915. The leading establishments in the state are located at Portland, Bar Harbor, Lewiston, Augusta, Bath, Bangor, Biddeford, Waterville, Freeport, Yarmouth, and Houlton.

Statistics (*Thirteenth Census*).

The approximate land area in 1909 was 19,132,800 acres. The land in farms was 6,296,859 acres or 32.9 per cent of the land area. The improved acreage in farms in 1909 was 2,360,657; the woodland in farms, 2,775,621; and other unimproved land in farms, 1,160,581. The total number of farms in 1910 was 60,016, the average acreage a farm being 104.9. [The total area of Maine is 33,040 square miles.]

The leading agricultural crops are hay and forage, forest products of the farms, and cereals. In 1909 hay and forage occupied 1,255,011 acres, or 53.2 per cent of the improved land area. The value of the products in 1909 was $15,115,821, which was 38.4 per cent of the total value of all crops. The value of the forest products of the farms in 1909 was $5,573,763, as compared with $2,652,252, their value in 1899. Cereals occupied 159,616 acres in 1909, the value of the production being $3,100,902.

Horticultural products grown are tree-fruits and nuts, small-fruits, potatoes and other vegetables, and flower and nursery products. The value of the fruits and nuts in 1909 was $2,215,116, as compared with $841,811 in 1899, an increase of 163.1 per cent. Small-fruits decreased in acreage from 1,585 in 1899 to 1,260 in 1909, when the value of the products was $233,124. The total acreage of vegetables, including potatoes, was 161,087, and their value $12,377,717. This was a marked increase over the acreage in 1899 when it was 91,777. The acreage of flowers and plants and nursery products decreased from 178 in 1899 to 169 in 1909, when the value of the production was $324,249.

The total quantity of orchard fruits produced in 1909 was 3,694,251 bushels, valued at $2,207,748. This was a marked increase over 1899, when the value of orchard fruits was $834,000. In 1909 apples contributed over 98 per cent of the total quantity; pears and plums and prunes most of the remainder. The number of bearing apple trees in 1910 was 3,476,616; those not of bearing age 1,045,123. The production in 1909 was 3,636,181 bushels of apples, valued at $2,121,816. The number of pear trees of bearing age in 1910 was 46,683; those not of bearing age, 13,013. The production in 1909 was 38,964 bushels, valued at $43,524. The plum and prune trees of bearing age in 1910 numbered 43,576; those not of bearing age, 22,491. The production in 1909 was 14,637 bushels, valued at $31,954. The more important of the other orchard fruits were 2,403 bushels of cherries, valued at $7,164; 2,014 bushels of peaches and nectarines, valued at $3,205; and small quantities of apricots and quinces, valued at less than $100.

The production of grapes is relatively unimportant in Maine. The total production in 1909 was 231,529 pounds, valued at $6,954. The vines of bearing age in 1910 numbered 9,731; and those not of bearing age 1,944.

Few nuts are grown in Maine. The total production of nuts in 1909 was 12,922 pounds, valued at $414. The value of the different nuts were as follows: butternuts, $152; chestnuts, $100; oil-nuts, $60; and black walnuts, $50.

Strawberries are by far the most important of the small-fruits grown in Maine, with raspberries and loganberries second in importance, closely followed by blackberries and dewberries. The acreage of strawberries increased from 512 in 1899 to 698 in 1909, when the production was 1,626,250 quarts, valued at $168,847. The acreage of raspberries and loganberries decreased from 131 in 1899 to 127 in 1909, when the production was 154,121 quarts, valued at $20,657. The acreage of blackberries and dewberries increased from 123 acres in 1899 to 145 in 1909, when the production was 153,816 quarts, valued at $15,931. The production of cranberries in 1909 was 100,192 quarts, valued at $7,957; that of currants, 76,031 quarts, valued at $6,986; and that of gooseberries, 65,867 quarts, valued at $5,881.

The potatoes are by far the most important of the vegetables. The acreage increased from 71,765 in 1899 to 135,799 in 1909, an increased acreage of 89.2 per cent. The production in 1909 was 28,556,837 bushels, valued at $10,224,714, which was 26 per cent of the total value of all crops. Other vegetables increased in acreage from 20,012 in 1899 to 25,288 in 1909, when the value of the products was $2,153,003. The more important of these vegetables were: 8,693 acres of sweet corn, valued at $272,614; 353 acres of cabbage, valued at $71,434; 472 acres of turnips, valued at $42,585; 257 acres of green peas, valued at $29,747; 201 acres of squash valued at $22,460; 60 acres of tomatoes, valued at $9,728; and 31 acres of cucumbers, valued at $8,185. Other vegetables grown were green beans, beets, carrots, cauliflower, celery, lettuce, onions, radishes.

The acreage devoted to the growing of flowers and plants increased from 71 in 1899 to 112 in 1909. The total area under glass at this time was 706,917 square feet, of which 624,472 were covered by greenhouses, and 82,445 by sashes and frames. The total value of the flowers and plants produced in 1909 was $301,005.

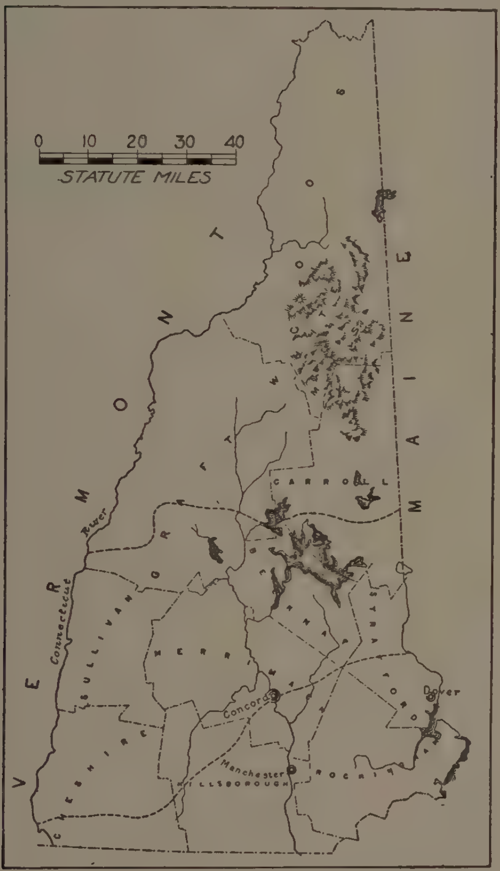
The acreage of nursery products, on the other hand, decreased from 107 in 1899 to 57 in 1909, a decrease of 46.7 per cent. The value of the nursery products in 1909 was $23,244, as compared with $46,207 in 1899.

E. F. Hitchings.

New Hampshire.

The soil of New Hampshire (Fig. 2488) is very variable. In fact there are practically no large continuous areas of any single type, and nearly every farm has several soil-types on it. In the main the soils are of granitic origin, being the result of glacial action together with a partial reworking of the glacial deposits by rivers and streams. Within narrow limits can be found all gradations of soil from sand to pure boulder clay, and they mostly carry a relatively high percentage of potash. In only a few sections of the state is any limestone soil found and the areas are rather limited. The soils of the valleys, coastal plains, and rounded hills are relatively fertile, but the highlands are rough, rocky, and mountainous and become more rugged as they extend northward until the White Mountains are reached. Roughly speaking, there is a high ridge, mountainous in parts, extending from the Massachusetts line on the south to the White Mountains on the north and which lies a little west of the central part of the state. This ridge is the watershed between the Connecticut River on the west and the Merrimac River to the east. It is on the east and south sides of this ridge that many of the best orchards of the state are located and an exceptionally fine type of apple, especially Baldwin, is grown in these locations.

The state may be divided into three sections, horticulturally, as shown in the accompanying map. In the lower section are found by far the largest fruit interests and north of this line there is practically none of the so-called tender fruits, such as peaches. In the central section, the apple and pear thrive and the opportunities for further development of the industry are excellent. The price of good apple land is reasonable and by means of the higher land a long-keeping, high-colored apple is produced. North of this central section there is little development of horticultural interests, although along the Connecticut River on the west and in northern Coos County to the north of the White Mountains, the hardier varieties of apples and small-fruits may be grown.



2488. New Hampshire, showing three agricultural divisions.

While the average rainfall for the state is 40 inches, the past few seasons have been much below this figure as recorded at Durham. In 1913, the rainfall for the year was 30 inches and in 1914, 31 inches.

The apple is the principal fruit grown in the state and may be said to be the leading horticultural product. The fruit thrives naturally throughout the southern half of the state as indicated by the large number of seedling trees that spring up through the open fields and along the fences. In fact, many of the bearing trees (especially the older orchards) are these seedling trees top-grafted to desirable varieties. It is a common sight in New Hampshire to see the apple trees planted along the stone walls or as scattered trees about the farms, rather than planted in orchards. This, however, is not true of the younger plantings.

Like most other sections of the country, there is a greatly renewed interest in the fruit business and a large number of trees have been planted in the past ten years. Also, many non-residents are planting a part of the farms about their summer homes to apples. In 1913, New Hampshire was awarded the first prize on her state exhibit of apples in competition with the other New England states, and several times New Hampshire Baldwins have won the sweepstakes prize at the New England Fruit Show. The commercial outlook for fruit-growing in the state is bright and the fact that some of the best markets in the country are practically at its door has stimulated much of the planting. Many growers ship exclusively to foreign markets and it is a short haul to place the fruit on the steamship pier at either Boston or Portland.

Modern methods of orchard management are being used by the progressive growers, a number are packing their apples in boxes and realizing the highest prices for them; power spray outfits are in use in a number of sections and proper cultural methods are being practised by more growers each year. But, notwithstanding this renewed interest, in many sections it must be noted that the older orchards are dying at an alarming rate; especially is this true in the southeastern part of the state. Many are cutting out their trees, deeming them worthless and impossible of renovation. The primary causes of this general dying of the old trees are the insect pests which have been defoliating the trees year after year and the fact that they are standing in sod and receive no stimulation of any kind. The brown-tail and gypsy moths are the most serious insects in the state and both feed freely on the apple trees. It is not difficult to control them in the orchard, and continued education and demonstration should do much to check their ravages. It is a more difficult matter to introduce tillage methods for the apple, partly because the growers fear the lack of color which commonly results and also because the trees are often scattered or along fences as above mentioned. Several notable examples in the state of the good results of orchard cultivation are having their effect and many of the young orchards are being tilled.

The varieties most commonly grown are Baldwin, Rhode Island Greening, Northern Spy, Fameuse, Blue Pearmain, King, and McIntosh. The last-named variety has been more largely planted than any other in recent years. In some sections the Nodhead or Jewetts Red is grown largely, also the Roxbury Russet, Gravenstein, Hubbardston, Wealthy, Porter, Tolman Sweet, Bethel, Twenty Ounce, and many of the older varieties. Among the newer plantings are found considerable numbers of Delicious, Stayman and Winter Banana, but their adaptability to this section has not been established.

Plums are grown only in a limited way and they are mostly of the Japanese varieties. The domesticas have been abandoned largely because of the prevalence of black-knot. The Abundance, Burbank, Chabot, and Red June are the varieties commonly grown and they are able to withstand the winters to a sufficient degree to warrant their recommendation.

Peaches are successfully grown in several sections, notably about Portsmouth, Rochester, Derry, Wilton, Lyndeboro, and Milford. Instances are reported on good authority of obtaining nineteen successive crops, but this is quite unusual, possibly three out of five being nearer the average of the more favored regions. Practically all the peach orchards are cultivated, and crim son clover and buckwheat are favored cover-crops. Peach-leaf curl is found to a sufficient extent to necessitate spraying for its control, but peach "yellows" is not known to exist and brown-rot causes very little trouble. San José scale is found in a few places. The varieties commonly grown are Greensboro, Carman, Mountain Rose, Early Crawford, Champion, Belle of Georgia, Elberta and Late Crawford. The Elberta is more largely grown than any other.

Cherries are grown in a very limited way, there being no orchard of any size, although both the Early Richmond and Montmorency do well. Pears are receiving very little attention at present.

The grape is planted in a few sections but the season is rather short to insure their proper maturity. The Concord, Worden, Delaware, Brighton, and Niagara are mostly grown.

Of the cultivated small-fruits, the strawberry and red raspberry are grown more largely than the others. There is an increasing demand for small-fruits throughout the state as a result of the ever-increasing number of tourists and summer residents. This phase of horticultural development offers good returns, especially where it is possible to practise irrigation.

By far the most important small-fruit, however, is the blueberry. The season extends from early July until mid-September. There are no statistics as to the actual quantity of blueberries produced in the state, but it is safe to say that it is several times greater than the quantity of strawberries. The low-bush blueberry is the earliest in ripening its fruit, followed by the medium and high-bush types. Probably two-thirds of the total crop are from the low-bush plants. New Hampshire and Massachusetts blueberries bring the highest prices on the Boston market. This is due to the fact that the berries are largely of the high-quality low-bush type and are almost all hand-picked. The low-bush blueberries are found mostly on fine, sandy, peaty soils on high lands. In many instances, the sides and rounded tops of hills in the southern and central parts of the state are covered with practically a pure stand of low-bush blueberries; on other hills it occurs in open spaces between clumps of the wild ground juniper and native wild spireas. The high and intermediate bush types are also found on high land but are more common on lower areas and on soils containing more moisture. A very limited start has been made in the cultivation of the high-bush blueberry. The low-bush type produces its finest fruit most abundantly on plants two and three years old, hence it is a common practice among owners of low-bush pastures to burn over a portion of the bushes each spring. Large shipping centers are the towns of South Lyndeboro, Greenfield, Alton and Milton, but almost all towns in the southern and central parts of the state ship at least in small quantities. They are usually marketed in the thirty-two-quart strawberry crates. The Boston dealers make a uniform charge of 2 cents a quart for selling, and the freight to Boston from most points in New Hampshire is 15 to 20 cents a crate. As a rule, the average price nets from 12 to 16 cents a quart at the first of the season and 8 to 10 cents a quart at the end of the season.

Market-gardening has been neglected in the past few years and as a result a large percentage of green stuff is shipped in from Boston, except in the height of the season. However, about Portsmouth and Dover and in the Merrimac Valley, considerable trucking is carried on. The Skinner system of irrigation is used in these sections and auto-trucks are used to some extent to market their product. Very little is done in growing vegetables under glass to supply the winter demands and most of the greenhouse vegetables are shipped in from Massachusetts.

Most of the greenhouses are found near the larger towns and cities and are mostly devoted to the growing of flowers. Roses are grown in a large way near Exeter and Dover. The growers attribute their success to the type of soil in these sections. One grower at Exeter has 96,000 feet of glass and another near Dover has 153,000 feet, all of which is devoted exclusively to the growing of roses for the Boston trade. The varieties grown are White and Pink Killarney, Killarney Brilliant, Ward, Richmond, and Sunburst.

Some very good examples of landscape gardening are to be found about Dublin and Peterborough. Most of the estates are owned by summer residents. In many other sections of the state this art is being manifested and considerable money has been expended in beautifying the estates. About the numerous summer hotels through the mountains may be seen some good examples of the landscape art. The farm homes are kept up unusually well. Most of the houses are large and the buildings are kept well painted. Many artistic libraries and churches are to be found in the rural districts.

A few varieties of apples have originated in New Hampshire which have become distributed to some extent throughout eastern United States. Among the best known of these are the Granite Beauty, Milden, Piper, and Red Russet.

Historically, New Hampshire can lay claim to an early recognition of the possibilities of growing fruit-trees and vines. In 1623, Ambrose Gibbons set the first vineyard, together with other fruits, near the mouth of the Piscataqua river near Portsmouth. There are many such old horticultural landmarks.

Many of the early settlers came from the southwestern counties of England. To them cider and perry seemed almost as necessary as food, and very soon after their arrival they began to set orchards of apples and pears. Their particular object was not the fruit itself, but the beverages made from it. The following item is taken from one of the many town histories that have been published in New Hampshire, and although it may be slightly exaggerated, it gives some idea of the apple industry one hundred years ago:

"About this time—1800 to 1810—the apple orchards in town which had been early set out, produced apples in abundance, which were made into cider. Every man had his orchard, and every tenth man his cider-mill. Every well-to-do farmer put into his cellar yearly from twenty to fifty barrels of cider which was all drunk on the premises. Col. John Bellows had an orchard of 30 acres, the largest in town. In 1805 there were 4,800 barrels of cider made and every drop drunk in town."

Public-service agencies for horticulture.

The New Hampshire College of Agriculture and the Mechanic Arts was created by an act of the Legislature in 1866 and was established at Hanover as a state institution, in connection with Dartmouth College. In 1893 the College was moved from Hanover to Durham. This action followed the death of Benjamin Thompson, of Durham, a farmer, who died January 30, 1890, and left his entire estate, with a few minor reservations, to the college. A department of horticulture was established in 1895, and at the present time there are five members of the horticultural staff, which includes one instructor who devotes his entire time to extension work.

The Experiment Station is located at Durham in connection with the Agricultural College. It was established in 1887. There are sixteen members of the staff at the present time, representing nine departments. The horticultural department has leased a Baldwin apple orchard near Durham for experimental purposes. There have been issued twenty-five bulletins on horticultural subjects.

The extension work in New Hampshire may be said to have had its real beginning in September, 1911. Among the activities of the extension service, the horticultural department has been carrying on some special demonstration work in several orchards.

The New Hampshire Horticultural Society was organized in 1893. It is in a prosperous condition.

There is a law in the state providing for the inspection of nursery stock, also a State Moth Department which has under its control the state and federal activities in the control of the gypsy and brown-tail moths.

Statistics (Thirteenth Census).

The approximate land area of New Hampshire in 1910 was 5,779,840 acres. The land in farms was 3,249,458 acres, or 56.2 per cent of the land area. Of this land in farms, 929,185 acres were improved; 1,502,389 were in woodland; and 817,884 acres other unimproved land in farms. The number of all the farms in 1910 was 27,053, and the average acreage to the farm 120.1. [The total area of the state is 9,341 square miles.]

The leading agricultural crops of the state are hay and forage, and cereals. The acreage occupied by hay and forage decreased from 615,042 in 1899 to 529,817 in 1909, when the value of the production was $7,846,143. Cereals decreased in acreage for the same period from 42,335 in 1899 to 32,928 in 1909, when their value was $879,631. The value of forest products of the farms in 1909 was $3,610,178, as compared with $2,296,265 in 1899.

Horticultural crops grown in New Hampshire are fruits and nuts, small-fruits, vegetables including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $734,387 as compared with $728,520 in 1899. Small-fruits decreased in acreage from 730 in 1899 to 618 in 1909, when the production was 998,244 quarts, valued at $107,365. In 1909 the total acreage of potatoes and other vegetables was 26,225 and their value $2,276,177. Excluding potatoes, the acreage of other vegetables increased from 7,357 in 1899 to 8,855 in 1909 when the production was valued at $1,071,551. The acreage devoted to flowers and plants and nursery products increased from 72 in 1899 to 117 in 1909, when the production was valued at $248,041.

The production of all the orchard fruits in 1909 was 1,165,044 bushels, a decrease of 42.3 per cent from the production in 1899. In 1909 apples constituted more than 95 per cent of the total production, and peaches and nectarines and pears most of the remainder. The production of apples in 1909 was 1,108,424 bushels, valued at $637,990. The number of apple trees of bearing age in 1910 was 1,240,885; those not of bearing age 207,289. The production of peaches and nectarines in 1909 was 23,218 bushels, valued at $37,884. The peach and nectarine trees of bearing age in 1910 numbered 57,571; those not of bearing age 35,213. The production of pears in 1909 was 24,224 bushels, valued at $25,206. The number of pear trees of bearing age was 36,816 and those not of bearing age 9,397. There were also produced in 1909: 7,542 bushels of plums and prunes, valued at $14,039; 1,403 bushels of cherries, valued at $4,133; quinces, to the value of $456; and apricots, to the value of $68.

The production of grapes and nuts in New Hampshire in 1909 was relatively unimportant. Grapes produced 375,164 pounds, as compared with 487,500 pounds in 1899. Their value in 1909 was $10,926. The production of nuts in 1909 amounted to 254,521 pounds, valued at $3,684. The nuts produced were 217,431 pounds of butternuts, valued at $2,597; 13,330 pounds of black walnuts, valued at $375; 8,446 pounds of hickory-nuts, valued at $303; and 5,479 pounds of chestnuts, valued at $242.

Of the small-fruits grown in New Hampshire, strawberries are the most important, with raspberries and loganberries ranking next. Strawberries increased in acreage from 307 in 1899 to 310 in 1909 when the production was 638,057 quarts, valued at $68,552. Raspberries and loganberries increased in acreage from 80 in 1899 to 85 in 1909, when the production was 86,558 quarts, valued at $11,821. Other berries produced in 1909 were 75,913 quarts of blackberries and dewberries, valued at $7,793; 43,319 quarts of currants, valued at $4,587; 30,304 quarts of cranberries, valued at $2,686; and 5,841 quarts of gooseberries, valued at $683.

The acreage devoted to potatoes in New Hampshire decreased from 19,422 in 1899 to 17,370 in 1909, when the production was 2,360,241 bushels, valued at $1,204,626. Excluding potatoes, the more important of the other vegetables produced in 1909 were 589 acres of sweet corn, valued at $28,835; 163 acres of cabbage, valued at $21,184; 51 acres of tomatoes, valued at $7,143; 68 acres of turnips, valued at $6,832; and 29 acres of onions, valued at $6,560. Vegetables of minor importance in 1909 were asparagus, green beans, beets, carrots, celery, cucumbers, green peas, squashes.

The raising of flowers and plant and nursery products is of little importance in New Hampshire. The acreage devoted to flowers and plants in 1909 was 93, as compared with 38 in 1899. The total area under glass in 1909 was 752,313 square feet, of which 719,848 were covered by greenhouses and 32,465 by sashes and frames. The value of flowers and plants produced in 1909 was $236,144. The acreage devoted to nursery products decreased from 34 in 1899 to 24 in 1909, when the production was valued at $11,897, as compared with $7,012 in 1899.

J. H. Gourley.

Vermont.

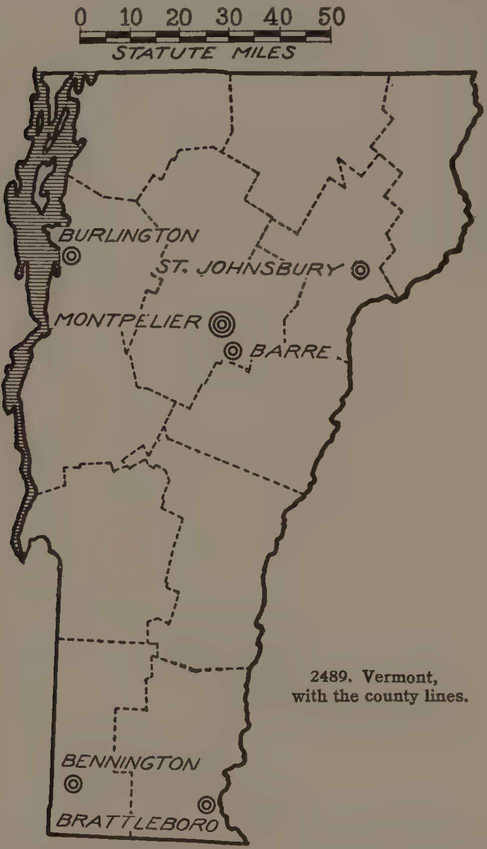
Vermont (Fig. 2489) is not and never will be a great horticultural state. Aside from the apple, strawberry, onion, and potato, the cultivable land is largely devoted to farm crops and dairying. The Champlain and Connecticut valleys are well adapted to fruit and vegetable crops. Apple orcharding throughout the state, but especially in sections noted above, offers the best opportunity. Much of the hill-town land should revert to forests.

In general, the soils of Vermont are well adapted to the culture of orchard-fruits. The limestone and granitic soils, especially on the west side, seem particularly fitted to the development of a thrifty long-lived tree. With but few exceptions, the soil is deep and retentive of moisture. The necessity for irrigation is the exception rather than the rule. Drainage is seldom necessary for orchard plantations; although for small-fruits and vegetables, tiling is desirable. Cover-crops are not used to the extent which their merit justifies.

The home markets for fruit and vegetables are unusually good. Strawberries rarely sell for less than 12½ cents a quart, and the average price for good fruit is probably nearer 15 cents. Blackberries usually bring 10 cents, and raspberries 10 to 20 cents. Cherries can generally be bought, the price being $3 to $4 a bushel. Good vegetables sell equally well. With such favorable markets, supported by numerous small manufacturing villages and a horde of summer boarders, horticultural industries certainly ought to thrive.

The horticultural regions of Vermont are, roughly, three. The first and most important is the Champlain Valley district, including several large islands in Lake Champlain. This region reaches toward Montreal on the north; and the general character of its horticulture is much like that in the St. Lawrence Valley between Montreal and Lake Ontario. Winter apples are the most important crop in this section. The second region lies in the southwestern part of the state and belongs to the upper Hudson Valley. Apples will grow readily when properly attended, but they are seldom cared for. Greater success is secured with small-fruits, the growing of which is greatly encouraged by the large annual immigration of summer residents. The third district comprises the valley of the Connecticut. It is the least developed of the three, horticulturally. The reason for this is not plain. Soil and climate are admirably adapted to all sorts of fruits. Even peaches are successfully grown in orchards. The few men who grow plums, cherries, strawberries, and so on, are proving every year that the Connecticut Valley in Vermont is naturally as much a fruit region as any other.

The apple crop in Vermont is fast assuming commercial proportions. There are many large orchards in every county, and in almost every town. Commercial orcharding is best developed on the western border, including the Champlain Valley, and extending southward to Bennington, where there is a 300-acre orchard. The market varieties are Rhode Island Greening, Northern Spy, Baldwin, Wealthy, Fameuse and McIntosh. The old family orchards of innumerable inferior varieties are rapidly disappearing through old age and neglect. The greatest plantings of apple trees in a generation have been made since 1910. Vermont has had experience with the Russian apples, T. H. Hoskins, of Newport, on the northern boundary of the state, having been one of the most famous experimenters. Nevertheless, the Russian varieties have made small impression on the pomology of the state.



2489. Vermont, with the county lines.

In all probability there are more extensive orchards in Vermont than in any other New England state. In 1870, the notable orchard of C. T. Holmes, of Charlotte, which embraces 105 acres, was set mostly to Rhode Island Greenings. In 1880, the famous Richford orchard in Highgate was set to a single variety,—Fameuse. Within a few years other orchards of similar proportions have been set. The most famous apple section of Vermont is in Grand Isle County, known to commercial men as the "Island Apple County." Grand Isle, which is the smallest county in the state, is the most important commercial apple section by reason of the small population and the relatively large proportion of the crop that is shipped out of the state. Each of the three separate islands of the county are entirely surrounded by the waters of Lake Champlain and enjoy thereby greater immunity from frost than other sections of the state. The first large orchard in the county (also in the state) was set in 1819, and embraced 20 acres, all of cider-apple stock which sold for 10 cents a bushel to French people from Canada. In 1848 and 1864 other large orchards were set, and in 1870 the work of planting trees was widespread. In 1912, the Eastern Fruit and Nut Orchard Company started its 215-acre orchard, which is interplanted with plums, cherries, and fillers. It is doubtful whether any region can produce apples of finer appearance, better quality or greater durability, than can be produced in Grand Isle, Vermont.

Plums are grown just enough to prove that they will succeed admirably. Lombard, Green Gage, Bradshaw, the Damsons and other old-fashioned sorts still retain preference of conservative Vermonters, although other growers are planting chiefly of the Japanese varieties, especially Burbank and Abundance. In the northern and mountain towns, only the americana and nigra types are hardy; but even these are seldom grown.

Pears have no commercial importance in the state. The localized orchards of a generation ago were swept out by the pear-blight, and the plantings replaced with apples. With proper care, the hardy varieties succeed.

Among cherries, Morello, Montmorency and Richmond are favorites. Raspberries are mostly red, the black berries being seldom grown. Cuthbert is the leading variety, though Schaffer and Columbian are gaining rapidly. Blackberries are carefully grown usually. Fine blueberries are picked from the fields in considerable quantities. Early varieties of grapes can be ripened for home use, Concord, Worden, Moore Early, Green Mountain and Delaware being leading varieties.

Vermont is remarkably free from many noxious insects and serious diseases. The area infected with San José scale is confined to a few towns in a single county in southeastern Vermont. The gypsy moth does not as yet occur in the state; and the brown-tail moth area is restricted to the southern and eastern borders, and further extension is being combated with vigor. Apple blotch and bitter-rot are not known to occur in the state. Crown-gall and hairy-root diseases are rare.

Truck-gardening is practised in the neighborhood of all the principal cities; but it cannot be said to be a well-managed business. Those crops which grow in special perfection are beans, potatoes, peas and tomatoes, salsify and parsnip. Those which cannot be grown, or which are, as a rule, unsuccessful, are melons, okra, sweet potatoes, and lima beans. Special crops which are sometimes grown in quantities for export are seed peas, white beans and onions.

On account of the long cold winter and the short and cloudy days of that season, the greenhouse industries have developed slowly. Notwithstanding this fact, many towns make demands for greenhouse products and every city in the state supports two or more greenhouses, devoted mostly to carnations, roses, chrysanthemums, lilies, and pot-plants.

There are three commercial nurseries in Vermont. One at Charlotte specializes in hardy ornamental shrubbery, and those at Waterville and Beebe Plains are apple nurseries.

Some very good examples of landscape gardening may be found about Bennington, Manchester, Shelburne, Burlington, and Woodstock, many of which are summer homes of city people. Island and shore camps in the Champlain district are especially attractive.

Several Vermonters of an earlier generation who were influential in either developing new horticultural varieties or testing the adaptability of varieties from other countries, were: C. E. Goodrich, originator of the Garnet Chile potato, and introducer of the Amazon, Calico, Cuzco, Central City, Rust Coat, and Pink

Eye potatoes; Albert Breese, of Hubbardston, originator of the Early Rose potato; Cyrus Pringle, of Charlotte, a scientific plant-breeder and eminent botanist (see Volume III, page 1591); E. C. Brownell, originator of the Brownell Best, Beauty, Eureka, Superior, and Winner varieties of potato; Albert Rand, originator of the Rand Peachblow potato, thought by some to be the Perfect or Improved Peachblow; and T. H. Hoskins, Newport, in the northern part of the state.

Public-service agencies for horticulture.

The Agricultural College of Vermont is located in Burlington, and is an integral part of the University of Vermont. In 1862 the Legislature chartered the Vermont Agricultural College, but it was not until 1865 that it was incorporated with the University. Instruction in horticulture was not begun until 1874, and in 1890 the department was established for instruction to students in the four-year course. The teaching is carried by one professor.

The Experiment Station is a part of the University and is coördinate with the College of Agriculture. There are three members of the horticultural staff. Twelve bulletins have been published on horticultural subjects, aside from annual report articles.

There are two state schools of agriculture, located at Randolph and Lyndon Center, where courses in horticulture are given. As a separate subject, horticulture is not taught in the public schools, although it receives some attention in a general agricultural course which is now offered in six public schools.

There is no state department of horticulture, although the State Commissioner of Agriculture devotes some time to horticultural welfare work. The inspector of nurseries is appointed by the Commissioner of Agriculture. An expert entomologist, similarly appointed has charge of the suppression of especially noxious insects.

Extension work in horticulture is carried on in connection with the College of Agriculture. The Vermont State Horticultural Society, organized in 1896, is also furthering the horticultural interests in the state.

Statistics (*Thirteenth Census*).

The approximate land area of Vermont in 1910 was 5,839,360 acres. The land in farms was 79.9 per cent of this area or 4,663,577 acres. Of this land in farms, the improved land numbered 1,633,965 acres; the woodland, 1,566,698 acres; and other unimproved land in farms, 1,462,914 acres. The total number of farms in Vermont in 1910 was 32,709, and the average acreage to the farm, 142.6. [The total area is 9,564 square miles.]

The leading agricultural crops of the state are hay and forage and cereals. The acreage devoted to the production of hay and forage increased from 1,006,375 in 1899 to 1,030,618 in 1909, when the production was valued at $16,335,530, which was 54.9 per cent of the total value of all crops. Cereals decreased in acreage from 160,127 in 1899 to 134,611 in 1909, when the production was valued at $2,651,877. Forest products of the farms in 1909 were valued at $3,638,537, as compared with $2,108,518 in 1899.

Horticultural crops grown in Vermont are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $818,851, as compared with $459,508, in 1899. Small-fruits increased in acreage from 418 in 1899 to 469 in 1909, when the production was 826,122 quarts, valued at $92,030. The total acreage of potatoes and other vegetables grown in 1909 was 35,408, and their value, $2,615,299. Excluding potatoes, the acreage of the other vegetables increased from 5,131 in 1899 to 8,548 in 1909, when the value of the production was $872,183. Flowers and plants and nursery products decreased in acreage from 112 in 1899 to 60 in 1909, when the production was valued at $89,740.

The total quantity of orchard-fruits produced in 1909 was 1,492,499 bushels, valued at $801,365. Apples contributed nearly all this quantity, and pears most of the remainder. Apple trees of bearing age in 1910 numbered 1,183,529; those not of bearing age, 219,833. The production in 1909 was 1,459,689 bushels, valued at $752,337. Pear trees of bearing age in 1910 numbered 26,315; those not of bearing age, 7,726. The production of pears in 1909 was 20,763 bushels, valued at $23,788. Other orchard-fruits produced in 1909 were: 7,205 bushels of plums and prunes, valued at $12,927; 2,506 bushels of cherries, valued at $7,651; 2,221 bushels of peaches and nectarines, valued at $4,399; and minor quantities of quinces and apricots.

The grape-production in 1909 was 203,011 pounds, valued at $6,328. The grape-vines of bearing age in 1910 numbered 9,318; those not of bearing age, 1,845.

The production of nuts in 1909 was 891,825 pounds, valued at $11,158. Butternuts were the most important of the nuts in 1909, the production being 845,899 pounds, valued at $9,872. Other nuts produced were: 32,910 pounds of black walnuts, valued at $725; 9,516 pounds of hickory-nuts, valued at $410; and 3,350 pounds of chestnuts, valued at $149.

Of the small-fruits grown in Vermont, strawberries are the most important, with raspberries and loganberries ranking next. The acreage devoted to the production of strawberries increased from 232 in 1899 to 276 in 1909, when the production was 615,820 quarts, valued at $68,690. Raspberries and loganberries decreased in acreage from 92 in 1899 to 80 in 1909, when the production was 85,065 quarts, valued at $10,596. Blackberries and dewberries decreased in acreage from 48 in 1899 to 47 in 1909, when the production was 56,252 quarts, valued at $6,032. Currants increased in acreage from 30 in 1899 to 58 in 1909, when the production was 58,533 quarts, valued at $5,684. In addition, there were produced in 1909, 7,424 quarts of gooseberries, valued at $728, and 1,120 quarts of cranberries, valued at $110.

Potatoes, the most important of the vegetables grown in Vermont, decreased in acreage from 28,353 in 1899 to 26,859 in 1909, when the production was 4,145,630 bushels, valued at $1,743,049. The more important of the other vegetables produced in 1909 were: 1,110 acres of sweet corn, valued at $35,650; 98 acres of cabbage, valued at $16,263; 29 acres of onions, valued at $6,780; 64 acres of turnips, valued at $6,543; 18 acres of tomatoes, valued at $4,236; 31 acres of cantaloupes and muskmelons, valued at $4,082; 39 acres of green peas, at $2,615; and 24 acres of beans, valued at $1,587.

The acreage devoted to the production of flowers and plants, decreased from 38 in 1899 to 23 in 1909. The area under glass in 1909 was 178,199 square feet, of which 162,339 were covered by greenhouses, and 15,860 by sashes and frames. The value of the flowers and plants produced in 1909 was $78,726, as compared with $58,575 in 1899.

Nursery products decreased in acreage from 74 in 1899 to 37 in 1909. The value of the nursery products in 1909 was $11,014, while their value in 1899 was $49,625.

M. B. Cummings.

Massachusetts.

The horticultural interests of Massachusetts (Fig. 2490) are fully equal to those of agriculture proper, when one considers the production of fruits, vegetables, flowers, and the labor and expense applied to the growth of ornamental trees, shrubs and plants and their use in decorating the homes, among which there are probably more comfortable, well-kept and beautiful homes than can be found in any similar area in the world. The people of this state probably consume more of the luxuries of life than any other people on the same area, and among the so-called luxuries may be classed fruits, fancy vegetables, and flowers.

The soil of Massachusetts is generally considered unproductive and poorly adapted to horticultural pursuits, and this is true in so far as it refers to large areas of exceptionally fertile land, of which that in the Connecticut Valley is the only section of more than a few acres in extent. Everywhere about the state, however, there are small areas of land suited to the growth of almost every crop succeeding in similar latitudes. By business enterprise, persistent effort, and skill, profitable horticultural crops can be grown. The local products largely supply the markets in their season. Apples are also exported.

There are no large areas devoted to the growth of either orchard- or small-fruits in Massachusetts, but small areas of nearly all these fruits are very profitably grown in most sections of the state. The amount of fruit produced within the limits of the state is not nearly up to the home consumption, except cranberries, and possibly the apple in some seasons. Even in seasons of an unusual crop in the state, large quantities of apples from other states are shipped into our markets, because in many cases they are of superior size and beauty.

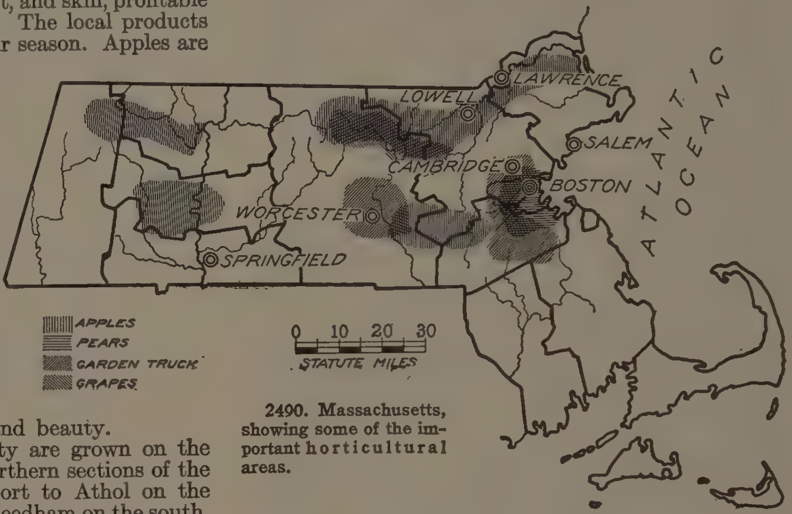
Apples of especially fine quality are grown on the granite soils of the middle and northern sections of the state, extending from Newburyport to Athol on the north, and from Northbridge to Needham on the south, and a small area in the Connecticut Valley.

Pears are grown in small areas within a short radius of most of the cities and large towns, eastern Massachusetts being particularly adapted to this fruit. Pears are also shipped into our markets from the southern states and California, and as the market for this fruit is limited, prices often rule very low.

Peaches of the finest quality are profitably grown more or less over the entire state on elevated land with a northern, northwestern, or northeastern exposure. On low land and that with a southern exposure the fruit-buds are winter-killed three years out of five. However, even under these conditions, when the trees are planted on rather light high land and well cared for, one crop in three years is often more profitable than most other fruit or vegetable crops. The fruit on trees well grown is large, of the finest color and quality, and the fresh, ripe condition in which the grower can put it into the local markets makes it quickly salable at the highest prices. The peach-belt may be included in that of the apple.

Plums are not grown to a great extent, the larger markets being supplied largely by New York and California. Few orchards remain productive longer than ten or twelve years, on account of the black-knot, leaf-blight and brown-rot. Within the past ten or fifteen years both European and Japanese plums have been largely planted, but they succeed only for a short time, except with the best care. They are planted in small numbers in poultry-yards and gardens.

The cherry, owing to the attack of the black aphis, the plum-curculio and brown-rot, is very little grown as an orchard-fruit. A few vigorous and productive trees may be seen here and there by the roadside, about old homesteads or on the lawn, where they live longer and attain greater size than when grown under a high state of cultivation in the garden or orchard, because of the fact that when grown too rapidly the trunks crack on the south side and the trees soon die. Our markets are largely supplied with cherries from California, New York, and other states.



2490. Massachusetts, showing some of the important horticultural areas.

Grapes have been more or less planted from Fitchburg on the north to Concord and Lexington on the south, but succeed only on elevated land with a southern exposure. Only the earliest varieties can be grown unless the fruiting canes are girdled.

Small-fruits are more grown and more nearly supply local markets than do the large fruits, but are grown only on small areas. The supply of very early fruit comes from the southern states of the country, but home-grown fruit is so much superior in quality that it sells at reasonable prices, notwithstanding prices may have been very much reduced by an over-supply of the southern product. Of the small-fruits, the strawberry is the most widely grown. There are no large areas especially devoted to strawberries, but most homes have strawberry-beds of good size. Currants are grown to a considerable extent, almost every garden containing more or less currant bushes for home supply, while many large plantations may be found near every large town or city. The conditions of success are a rather moist, rich soil, with the bushes trained into a very compact form and pruned so that the fruit will be borne on wood that is not over three or four years old. Gooseberries are little grown, although the demand is rather on the increase. The more hardy kinds can be as easily grown as the currant, while the European sorts and their hybrids, many of them, require much care and skill. Like the currant, the blackberry is largely grown for home use, and also for market. It succeeds upon a great variety of soils, can be grown cheaply and sells at good prices. Few plantations will be profitable on the same land more than from five to seven years unless the soil is strong and rich. It is the practice of most growers to plant a new lot every six or seven years. The red raspberry is the most popular of the bush-fruits, and when successfully grown is the most profitable. For success it requires a deep sandy loam, retentive of moisture, but plantations must be renewed after six or eight years' growth on one piece of land. The blackcap raspberry has found less and less favor each year, and can only be sold at very low prices in the city markets.

The business of market-gardening has made rapid strides in the state in the past ten years, and the demand for choice vegetables continues more or less the year round. Even in the matter of competition with vegetables from the South during the winter, the local growers have reached a good degree of success. The truck-gardens are mostly located near large cities where products can be shipped by freight or express. In almost every part of the state may be found forcing-houses for the growth of lettuce, tomatoes, cucumbers, rhubarb, asparagus, and the like, and notwithstanding the cost of such structures and the fuel to keep up the necessary heat, the increase in the number of forcing-houses in the state within the past few years is a certain indication that the business is profitable.

It is perhaps in the growth of cut-flowers and house and decorative plants that Massachusetts excels in horticulture. As a rule, the largest establishments of this kind are located near the large cities, though in some cases they may be found in some of the more rural towns. The horticulturists of Massachusetts understand their advantages in having the best markets in the world at their doors, and a great variety of the soils suitable for the growth of many of the varied crops. By persistent effort and superior skill they could supply these markets largely, and thus retain within the state much of the wealth that now goes outside to pay for the produce that could be raised at home.

In commercial horticulture, Massachusetts is not the equal of some other states, although its market-gardening and floricultural interests are large, but its influence on the horticulture of the country is more important than acres and tonnage. The best horticulture is that which develops under difficulties, because it develops the man. The love of the country and attachment to its own soil are strong in Massachusetts. Individuality has full course. It is a land of home-loving people. It has developed the amateur horticulturist to perfection,—the person who grows the plant and dresses the soil for the very love of it. There are many large collections of choice plants, and great numbers of artistic, compact and tidy garden-homes. There is keen appreciation of the merit of well-grown things. The influence of the Massachusetts Horticultural Society has been incalculable. It is our oldest and strongest geographical organization. Since 1829 it has had its stated discussions, held its periodical shows, collected its library and records. It is a center of education and culture. The establishment of Mt. Auburn Cemetery, Cambridge, in 1831 was the beginning of the movement in this country for cemeteries in the open as distinguished from the churchyard.

A list of persons influential in developing the horticulture of Massachusetts must necessarily be incomplete, as so much amateur and professional interest in horticulture has developed in this state. The following persons, however, may be mentioned: Marshall P. Wilder (see Volume III, page 1603); Robert Manning (page 1587); C. M. Hovey (page 1580); W. C. Strong (page 1598); O. B. Hadwin. W. W. Rawson (page 1593); Jabez Fisher, and many others. "The History of the Massachusetts Horticultural Society," published in 1880, should be consulted for many other personalities.

Public-service agencies for horticulture.

The land-grant college of Massachusetts was established at Amherst in 1865, and opened for work in 1867. There are at present seven members of the horticultural staff.

The Experiment Station is also located at Amherst, being established in 1882. Its horticultural staff numbers fifteen members.

Extension work is also carried on throughout the state. Bureaus are being established in each county, which are giving invaluable aid to the horticulturist.

The State Board of Agriculture supports a series of lectures upon agricultural and horticultural subjects.

Several counties have established agricultural and horticultural schools, and a few of the high-schools are introducing these courses.

Special inspectors are appointed for nursery inspection and the control of insect pests and diseases. There are also special bee inspectors.

Statistics (*Thirteenth Census*).

The approximate land area of Massachusetts in 1910 was 5,144,960 acres. The land in farms numbered 2,875,941 acres, or 55.9 per cent of the land area. The improved land in farms numbered 1,164,501 acres; the woodland in farms 1,064,553; and other unimproved land in farms 646,887. The number of all the farms in 1910 was 36,917; the average acreage to a farm being 77.9. [The total area is 8,266 square miles.]

The leading agricultural crops are cereals, hay and forage, and tobacco. There was a slight increase in the acreage occupied by cereals from 53,385 in 1899 to 55,267 in 1909, when the value of the products from cereals was $1,617,131, or 5.1 per cent of the total value of all crops. The acreage devoted to hay and forage decreased from 610,023 in 1899 to 519,503 in 1909, when the value of the production was $11,280,989, or 35.3 per cent of the total value of all crops. The acreage of tobacco increased from 3,826 acres in 1899 to 5,521 acres in 1909, when the value of the production was $1,218,060. The value of forest products produced on the farms in 1909 was $2,668,410, as compared with $1,944,714, their value in 1899.

Horticultural crops are the fruits and nuts; small-fruits; vegetables, including potatoes; and flowers and plants and nursery products. In 1909 the value of the fruits and nuts produced was $2,108,799, as compared with $1,218,659, the value in 1899. The acreage of small-fruits increased from 8,346 in 1899 to 9,552 in 1909, when the value of the small-fruits was $1,676,790, or 5.2 per cent of the total value of all crops. In 1909 the total acreage of potatoes and other vegetables was 61,686, and their value $8,184,213. The acreage of vegetables, excluding the potato, was 37,220 and their value $6,189,857, both acreage and value being decidedly greater than in 1899. The raising of flowers and plants and nursery products is of relative importance. The acreage increased from 1,478 in 1899 to 2,750 in 1909, when the value of the products was $3,061,342, which was 9.6 per cent of the total value of all crops.

The total quantity of orchard-fruits produced in 1909 was 2,763,679 bushels, valued at $2,074,270. Apples contributed more than nine-tenths of this quantity; peaches and pears most of the remainder. The number of apple trees of bearing age in 1910 was 1,367,379; those not of bearing age, 355,868. The production in 1909 was 2,550,259 bushels, valued at $1,780,290. The number of peach and nectarine trees of bearing age in 1910 was 154,592; those not of bearing age, 162,114. The production in 1909 was 91,756 bushels, valued at $138,716. The number of pear trees of bearing age in 1910 was 113,365; those not of bearing age, 38,378. The production in 1909 was 96,071 bushels, valued at $110,069. In addition, 17,814 bushels of plums and prunes were produced in 1909, valued at $28,253; 4,761 bushels of cherries, valued at $10,848; 2,863 bushels of quinces, valued at $5,754; and minor quantities of apricots and mulberries.

Grape-growing has little significance in Massachusetts. In 1910 the grape-vines of bearing age numbered 58,277; those not of bearing age, 14,261. The production in 1909 was 1,132,838 pounds, valued at $30,858.

Nuts are of less importance than grapes. The total production in 1909 was 134,920 pounds, valued at $3,671. The leading nuts were: 40,064 pounds of black walnuts, valued at $1,219; 60,151 pounds of butternuts, valued at $984; and 23,834 pounds of hickory-nuts, valued at $904.

Cranberries are by far the most important of the small-fruits grown in Massachusetts, with strawberries second in importance. The acreage of cranberries increased from 5,128 in 1899 to 6,577 in 1909, when the production was 22,714,496 quarts, valued at $1,062,205. The acreage of strawberries for the same period decreased from 2,027 in 1899 to 2,015 in 1909, when the production was 5,518,867 quarts, valued at $495,438

The more important of the other small-fruits produced in 1909 were 376,136 quarts of raspberries and loganberries, valued at $55,757; 307,987 quarts of blackberries and dewberries, valued at $31,454; 213,810 quarts of currants, valued at $19,904; and 57,827 quarts of gooseberries, valued at $5,007.

The potato is by far the most important of the vegetables. The acreage decreased from 27,521 in 1899 to 24,459 in 1909 when 2,946,178 bushels were produced, valued at $1,993,923. Among the leading vegetables grown in 1909, excluding potatoes, were: 2,493 acres of onions, valued at $624,630; 2,442 acres of cabbage, valued at $426,586; 1,187 acres of celery, valued at $368,854; 4,942 acres of sweet corn, valued at $355,953; 1,228 acres of tomatoes, valued at $268,380; 372 acres of cucumbers, valued at $179,084; 776 acres of asparagus, valued at $116,622; 1,068 acres of turnips, valued at $95,754; and 555 acres of squash, valued at $91,388. Vegetables of minor importance in 1909 were green beans, beets, carrots, cauliflower, eggplant, parsnips, green peas, green peppers, radishes, rhubarb and spinach.

The acreage devoted to the production of flowers and plants increased from 584 in 1899 to 1,203 in 1909, an increase of 106 per cent. The total area under glass in 1909 was 7,382,009 square feet, of which 6,817,585 were covered by greenhouses, and 564,424 by sashes and frames. The value of the flowers and plants produced in 1909 was $2,455,467, as compared with $1,639,760 in 1899.

The acreage devoted to nursery products increased from 894 in 1899 to 1,547 in 1909, an increase of 73 per cent. In 1909 the value of nursery products was $605,875, as compared with $260,069 in 1899.

S. T. Maynard.

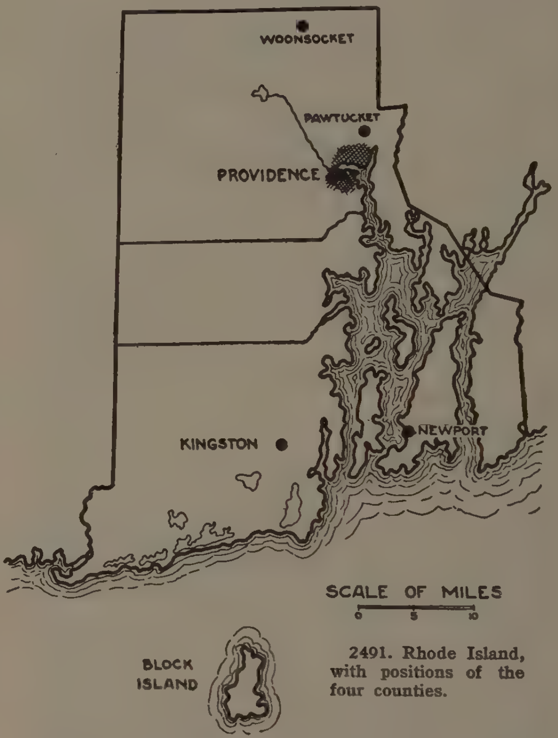
Rhode Island.

The general topography of Rhode Island (Fig. 2491), is of a hilly nature, tending to become more broken after leaving the ocean shores of the southern part of the state and of Narragansett Bay, which extends as a triangular body of water from Long Island Sound to Providence. This bay with its numerous islands and fine shores has resulted in the development of a number of summer resorts which furnish an excellent market for locally grown horticultural products.

Geologically there are within the state two distinct physiographic provinces, the eastern or Narragansett basin area, which comprises the eastern third of the state, and the western or more mountainous area of hill remnants from one of the ancient east Appalachian mountain ranges. Included within the Narragansett area are the islands of the bay and an area which follows the western shore of the bay, extending at no point more than 3 miles inland, and from the head of the bay, it extends northward across the boundary of the state. Topographically, this region consists of smoothly rounded hills, not exceeding 250 feet in height, and of gently rolling glacial plains. The inland or rougher area consists of rough and stony hills. Considerable areas of fresh-water swamps are found within this province; there are also many small lakes. The state lies wholly within the glaciated area.

The average annual rainfall for the state is approximately 48 inches, being somewhat greater than this in the southern section of the state which is locally influenced by proximity to tidewater.

With a population of 508.5 to the square mile, there is furnished a market for horticultural produce which is far in excess of the ability of the state to supply. This condition, together with the close proximity of both the Boston and New York markets, affords market conditions most favorable for an intensive horticultural development in the future. With 96.7 per cent of this population classed as urban, the demand created for perishable food-products has resulted in the development of vegetable-gardening as one of the most specialized horticultural industries of the state. The regions where this specialization has been most largely developed have the cities of Providence and Newport as their centers. In addition to the cities, the many villages devoted to manufactures and the summer resorts furnish markets that are supplied by producers who cannot be classified as market-gardeners, yet who derive a very substantial proportion of their cash income from the growing of vegetables and fruits. It is this class of growers which exert a very marked influence upon the agricultural prosperity of the state



2491. Rhode Island, with positions of the four counties.

The sandy soil types of the state, when abundantly supplied with water, are well suited to the growing of high-quality vegetable products. Although all of the different vegetables are grown in abundance, the following may be mentioned as of special importance: lettuce of the hard-headed Boston market type, the loose-leaf varieties being practically unknown in the wholesale markets; tomatoes are produced in large quantities, the larger growers relying almost entirely upon the Stone or some improved strain thereof; green corn is a profitable crop, large quantities of which are used for roasting with clam dinners served daily at many of the shore resorts throughout the season. The standard variety for this trade is the Potter's Excelsior corn. Vegetable-growing will be the most important commercially of any horticultural enterprise for many years to come.

Building of improved roads by the state, together with the development of the automobile as a means of getting farm produce to market, is beginning to exert a marked influence upon the areas devoted to horticultural products. This is shown most conclusively in the areas which are being planted to the tree-fruits in the northwestern section of the state. The rough land in this section which has heretofore been inaccessible to market, on account of lack of transportation facilities, is capable of producing fruit of high color and quality. Varieties of fall apples, such as the Gravenstein, find a ready market at remunerative prices, while for the main crop, the standard varieties are Rhode Island Greening, Baldwin, McIntosh and Spy. Of the stone-fruits, the peach is the most largely grown, orchards being found in all sections of the state. Those growers whose orchards are situated on the higher slopes along the shores of Narragansett Bay and upon the island of Rhode Island suffer much less injury from winter-killing of the buds and frost-injury in the spring than do those growers whose orchards are located farther inland; the latter, however, have less trouble with the various fungous diseases. The area devoted to the peach is being extended each season, particularly in the counties of Bristol and Newport. Cherries and plums are grown only in very limited quantities, the local markets being supplied almost entirely by shipments from other states. The plum is being grown profitably in those sections removed from the seashore. Of the cherries, the sour varieties are the most profitable, on account of the great difficulty in growing the sweet varieties in many sections, and are now being planted more than formerly.

Pears are not produced in large quantities for market, although the total number of trees of this fruit is large, as it is more commonly grown in the small house-lot than any other fruit. To such an extent is it produced upon these small holdings that the market demand for the summer and early fall varieties is very limited while for the later varieties, such as Bosc, Lawrence and Sheldon, there is an unsupplied demand in the city markets which would probably justify the commercial planting of this fruit.

In the production of varieties of fruit the state has played little part, its most important contributions being the Rhode Island Greening apple and the Buffum pear.

Of the small-fruits, strawberries and cranberries are of the most importance commercially. The acreage devoted to the small-fruits has shown a very material decrease in recent years. The largest production of strawberries is in Providence and Newport counties, the crop being grown almost entirely in wide matted rows. Cranberries are most largely produced in Providence and Washington counties. When proper attention is given to the bogs, they are the most profitable of the farm areas; the bulk of the crop is produced upon natural bogs which are overflowed during the winter months by adjacent streams. The prices received are such as to justify the paying of more attention to this crop, as many of the natural bogs are so located as to be easily flooded at a comparatively small expenditure.

Currants, raspberries and gooseberries are mostly grown for home consumption with the result that the markets are never properly supplied. The prices received for these fruits are such as to make them profitable when grown under commercial conditions. Blackberries are not profitable as a rule, owing to the extensive areas of the wild fruit throughout the state.

Of the horticultural changes during the past decade, the most marked has been the decrease in the production of vegetables under glass and the increase in floricultural products. Many large ranges of glass which were formerly wholly or in part devoted to the production of lettuce, tomatoes and cucumbers, are now being used for the growing of roses, carnations and lily-of-the-valley. The area under glass devoted to the production of flowers has more than doubled in the past decade. Where formerly the trade was confined almost entirely to cut-flowers, now much attention is being given to the production of potted plants for home-decoration. Vegetable-forcing at present is being conducted, in most cases, as an adjunct to the general market-gardening business, forcing vegetables to maturity only at those seasons of the year when the houses and hotbeds are not needed for growing of stock for transplanting to the fields.

Nursery stock is receiving much more attention than formerly, the area devoted to the growing of nursery stock having been increased two and one-half times during the past ten years. The business is confined almost entirely to the growing of ornamental trees and shrubs. On the island of Rhode Island are several nurseries which make a speciality of those plants best suited for planting near the seashore. Stock from these nurseries, while not making so large a growth of tops as that produced farther inland, has a root-system which is unexcelled.

Throughout the state are many fine estates, among which may be mentioned the many summer homes in the vicinity of Newport, where the famous cliff walk is lined for several miles with beautiful lawns and grounds, some of which are noted for the fine collections of ornamental trees and shrubs. While one is constantly reminded that Rhode Island is primarily a manufacturing state, yet the large number of fine suburban homes, the small grounds of which are planted with most excellent taste and upon which are found growing collections of fruits which furnish a succession throughout the entire season, shows a high appreciation of nature upon the part of many of her inhabitants.

The metropolitan park system of the state centered at Providence, which has for its object the development of pleasure-grounds and the conservation of historical sites, is receiving liberal support and the commission in charge of the work is rendering a most valuable service to the state in the development of love for the beautiful in nature.

Throughout the state many farms which have been neglected by their former owners are passing into the hands of foreigners, especially Italians and Portuguese, who are clearing much of the rough land of rocks and brush and using the land for the growing of truck and fruit. The immediate development of the state will be away from the general farm crops and toward the growing of the more perishable crops. There are within the state most excellent opportunities for the development of horticultural enterprises, either along the fruit or vegetable lines, as the urban population is increasing much more rapidly than the population engaged in the production of foodstuffs.

Among those individuals who have exerted a marked influence upon the horticultural development of the state, the following may be mentioned: Solomon Drowne, M.D. (1753–1834), who was professor of botany in Brown University, and in 1824 published "The Farmer's Guide, a Comprehensive Work on Husbandry and Gardening;" the Moore family for many years were very active in the development of fruit-growing and ornamental horticulture in the state, especially Silas Moore (1818–1879), nurseryman; Robert E. Moore (1820–1902), orchardist; Robert I. Moore, (1835–1899), landscape gardener; James Nesbit, landscape gardener; and James A. Budlong (1823–1895), market-gardener.

Public-service agencies for horticulture.

The leading agency in the dissemination of horticultural information throughout the state is the Rhode Island State College located at Kingston. This institution was established by act of the state legislature, March 23, 1888, as the Rhode Island State Agricultural School, the first class entering in September, 1890. On May 19, 1892, the institution was incorporated by the state legislature and its name changed to the Rhode Island College of Agriculture and Mechanic Arts. Again, after the passage of the Adams Act by Congress, the name was changed to the Rhode Island State College, this change occurring May 4, 1909. There are two teaching members of the horticultural staff.

The Rhode Island Experiment Station, located at Kingston, is a department of the State College, its work being conducted by a staff of seventeen. At present there is no horticulturist upon the staff. There have been published nineteen horticultural bulletins, besides numerous horticultural articles in the annual reports.

Horticulture is not taught in any of the public schools of the state as a text-book subject. School-gardens were established by the Extension Department of the State College in 1905, which work has developed very rapidly since 1908, the coöperation of the State Board of Agriculture and school authorities of the various cities and towns having been secured at that time. In addition to the school-garden work, the Extension Service conducts orchard demonstrations in spraying and pruning.

The State Board of Agriculture is by law empowered to employ an entomologist who has charge of all nursery inspection work in connection with insect pests and diseases.

The most important societies of horticultural interest in the state are the Rhode Island Horticultural Society of Providence, Newport Horticultural Society, Florists' and Gardeners' Club of Providence and the Providence Market-Gardeners' Association. The latter society has for its object the betterment of conditions under which the growers for the Providence market dispose of their produce.

Statistics (*Thirteenth Census*).

The approximate land area in 1910 was 682,880 acres. The land in farms was 64.9 per cent of the land area, or 443,308 acres. Of this land in farms, the improved land numbered 178,344 acres; the woodland, 185,909 acres; and other unimproved land in farms 79,055 acres. The number of all the farms in 1910 was 5,292, and the average acreage was 83.8. [The total area of Rhode Island is 1,248 square miles.]

The leading agricultural crops of the state are hay and forage and cereals. The acreage devoted to hay and forage decreased from 69,776 in 1899 to 61,327 in 1909, when the production was valued at $1,309,717, which was 33.3 per cent of the total value of all crops. Cereals increased in acreage from 10,552 in 1899 to 12,112 in 1909, when the production was valued at $376,097. The value of the forest products of the farms was $312,022 in 1909, as compared with $195,472 in 1899.

Horticultural crops produced in Rhode Island are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of fruits and nuts produced in 1909 was $207,844, as compared with $160,411 in 1899. Small-fruits decreased in acreage from 581 in 1899 to 281 in 1909 when the production was 437,560 quarts, valued at $43,033. The total acreage of potatoes and other vegetables in 1909 was 9,924, and their value $1,045,093. Excluding potatoes, the other vegetables increased from 5,165 in 1899 to 5,275 in 1909, when the production was valued at $636,656. Flowers and plants and nursery products increased in acreage from 263 in 1899 to 502 in 1909, when the production was valued at $634,087.

The production of orchard fruits in 1909 was 245,822 bushels, valued at $197,639. Apples produced most of this quantity, and peaches and nectarines and pears most of the remainder. The number of apple trees of bearing age in 1910 was 152,009; those not of bearing age 54,560, and the production in 1909 was 212,908 bushels, valued at $147,125. Peach and nectarine trees of bearing age in 1910 numbered 39,342; those not of bearing age 30,795, and the production in 1909 was 17,704 bushels, valued at $30,609. Pear trees of bearing age in 1910 numbered 16,907; those not of bearing age 5,405 and the production in 1909 was 12,501 bushels, valued at $14,577. Other orchard fruits produced were: 1,872 bushels of plums and prunes, valued at $3,586; 618 bushels of quinces, valued at $1,267; and 214 bushels of cherries, valued at $464.

The production of grapes in 1909 was 152,937 pounds, valued at $9,759. The grape-vines of bearing age in 1910 numbered 7,662; those not of bearing age, 9,634. Nuts are of little importance, the production in 1909 being valued at $49.

Strawberries are the most important of the small-fruits grown in Rhode Island. The acreage of strawberries decreased from 154 in 1899 to 140 in 1909, when the production was 326,540 quarts, valued at $31,712. Cranberries decreased in acreage from 300 in 1899 to 70 in 1909, when the production was 34,688 quarts valued at $2,734. Raspberries and loganberries decreased in acreage from 57 in 1899 to 34 in 1909, when the production was 32,871 quarts, valued at $4,197. Other small-fruits produced in 1909 were: 17,875 quarts of blackberries and dewberries, valued at $1,927; 17,110 quarts of currants, valued at $1,564 and 8,251 quarts of gooseberries, valued at $852.

Potatoes in Rhode Island decreased in acreage from 5,816 in 1899 to 4,649 in 1909 when the production was 552,677 bushels, valued at $408,429. The more important of the other vegetables produced were: 790 acres of sweet corn, valued at $49,440; 37 acres of celery, valued at $26,880; 192 acres of cabbage, valued at $25,818; 152 acres of onions, valued at $23,828; 187 acres of tomatoes, valued at $22,898; 196 acres of turnips, valued at $21,050; 199 acres of cucumbers valued at $18,330; 93 acres of asparagus, valued at $17,504; 154 acres of beans, valued at $13,305; 11 acres of lettuce, valued at $14,670; 205 acres of peas, valued at 12,790; and 8 acres of radishes, valued at $10,269. Vegetables valued at less than $10,000 were beets, cantaloupes and muskmelons, carrots, cauliflower, eggplant, parsnips, green peppers, pumpkins, rhubarb, spinach, and watermelons.

The acreage devoted to the production of flowers and plants increased from 177 in 1899 to 290 in 1909. The total area under glass in 1909 was 2,027,643 square feet. Of this area 1,882,314 square feet were covered by greenhouses, and 145,329 by sashes and frames. The value of the flowers and plants produced in 1909 was $558,543, as compared with $314,806 in 1899.

The acreage devoted to nursery products increased from 86 in 1899 to 212 in 1909, when the value of the products was $75,544, as compared with $42,295, the value of the nursery products produced in 1899.

George E. Adams.

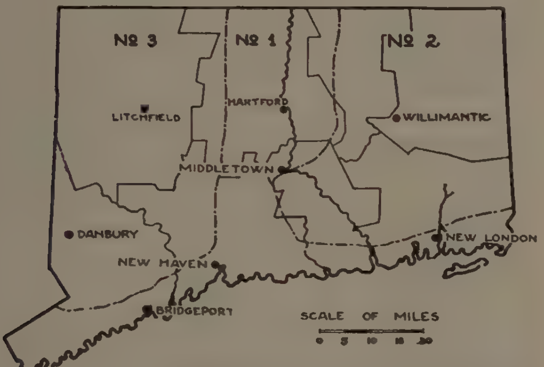
Connecticut.

While Connecticut (Fig. 2492) is one of the smallest states, covering but one degree of latitude (41° to 42°), it is adapted to as wide a range of horticultural productions as any state outside of the semi-tropic fruit-belt, owing to the great diversity of soil and varying elevations, from the sea-level along the whole southern border, to 900 and 1,200 feet in sections of Tolland County, and 1,200 and 1,500 in parts of Litchfield. The "season" of many of the quick-maturing species and varieties of fruits, flowers and vegetables is often entirely over on the light soil in the Connecticut Valley and along the Sound shore when like species and varieties are but just beginning to ripen on the cooler, moist soils of the hills of Tolland and Litchfield counties.

Strawberries and green peas from East Hartford and Glastonbury supply the Hartford market, while on the Bolton hills, only 12 miles away, the blooming vines give promise of the crop that is to come after the valley season is entirely over; so that "home-grown" strawberries are usually to be had in the Hartford market for a period of six or seven weeks. The Sound shore, Housatonic Valley and Litchfield hills supply

New Haven, Bridgeport and other cities of the state through equally long seasons.

From the earliest settlement of the state, fruit-growing for the family home-supply has been a prominent feature of Connecticut agriculture, the apple being a main reliance. The old seedling trees scattered over all our farms today are plain evidence that our ancestors took their apple-juice through the spigot of the cider-barrel rather than fresh from the pulp of the ripe fruit of some finer variety. A hundred years ago every farmhouse cellar wintered from thirty to fifty barrels of cider, while today it is hardly respectable to have any, and probably not one family in ten now has even one single barrel on tap as a beverage. Yet in quantity and variety the family fruit-supply has wonderfully increased and a daily supply of fresh home-grown fruit is the rule rather than the exception in most farm homes,—small-fruits in variety, apples, pears, peaches, plums (both European and Japan), cherries and quinces, in all the best standard varieties, coming to their highest perfection in every section of the state when rational methods of culture are followed.



2492. Connecticut, marking the three main horticultural districts.

Natural timber and semi-abandoned farm- and pasture-lands, growing up to brush and timber, with increasing acreage yearly up to the beginning of the twentieth century, are now furnishing the "new lands" for extensive horticultural enterprises and many thousands of acres of these lands have been cleared and planted to peaches, apples and grapes within the past fifteen years, particularly in Hartford, Tolland, Middlesex and New Haven counties, mostly by newcomers from the north of Italy, although a few of the large developments have been made by old-time pioneer orchardists. Lying midway between New York and Boston, the greatest horticultural markets of America, Connecticut is better situated than any other state in the Union to realize quick cash returns from her horticulture. Every farm is within driving distance of some one or more of the busy manufacturing towns and villages, whose people are appreciative of choice fruits and are able to pay for them.

District No. 1 comprises the Connecticut River valley and adjacent hills, along the Northampton branch and the main line of railroad from Hartford to New Haven, and all of the shore towns. This region contains most of the sandy plain lands of the state, and the loams and clay most free from rocks and stones. On the hills back from the river, on the ridges either side of the railroads, and a few miles back from the Sound shore, there are many places where soil and topographical conditions are much the same as in districts Nos. 2 and 3; but, having much larger tracts of easily cultivated lands, and being better located as to market conditions, this district is more highly developed horticulturally than either of the others. Here are the great market-gardens and small-fruit farms, peach-orchards, vineyards and melon-fields.

District No. 2 comprises Tolland and Windham counties and all of the Middlesex and New London counties, except Cromwell and the shore towns, and is particularly well suited to apple- and peach-culture, owing to the rolling condition of the country and natural fertility of many of the hills. Every few miles are little valleys and pockets suited to the production of small-fruits and vegetables in variety. A few townships in the northeast grow apples rather extensively, while in the west and southwest commercial peach-orchards are found to considerable extent.

District No. 3 comprises western Hartford, northwestern New Haven, northern Fairfield, and all of Litchfield counties, and is somewhat similar to district No. 2, except that the soil is generally heavier, with rather more mixture of clay and the hills are more abrupt and rocky. Some sections of Litchfield County are too cold and bleak for any but the most hardy fruits. Apples grow freely everywhere, and, while always of good quality, the brightest colors, firmest texture and highest quality of fruit is produced on the rocky hills, at an elevation of 300 to 1,000 feet. Baldwin, Rhode Island Greening, Roxbury Russet and Spy are the leading varieties, although all the varieties that thrive well in the northeastern United States grow to perfection here when properly cared for, and in the new orchard developments of the past ten years, Wealthy, McIntosh, Banana and Delicious have been very extensively planted.

Peach-culture on an extended scale is a recent development. Thirty-five years ago the only commercial orchard in the state contained about 2,000 trees, and probably 5,000 trees would be a liberal estimate for the state at that time; now upward of 1,000,000 peach trees are grown in the state. While many varieties are grown, the main plantings are of Greensboro, Carman, Hiley, Champion, Belle of Georgia and Elberta, of the North China type, an almost entire abandonment of the older Persian types as formerly grown, such as Mountain Rose, Oldmixon and the Crawfords. High culture, close pruning, spraying and a thinning of the fruit are generally practised, and fruit of brightest color, largest size and high quality is thus secured. In the markets of this and neighboring states, "Connecticut peaches" usually sell at a much higher price than those from any other section. The only serious drawback is the winter-killing of the fruit-buds in the valleys when temperature drops to 10° to 20° below zero, this happening probably two years out of five, while on many hillsides and hilltops at least four crops out of five are assured; but there are many favorable localities where annual crops are almost a certainty.

Japanese plums, largely planted from 1895 to about 1905, were for a few years very vigorous, productive and profitable, Abundance, Burbank, and Red June being the most acceptable varieties. Of recent years, however, the trees have become very short-lived and their commercial planting has been almost entirely abandoned.

Raspberries, blackberries, currants and gooseberries grow and produce freely all over the state, and all local markets are abundantly supplied in season.

Grapes are grown successfully all over the state, except on the highest and coldest hills; and on the sandy plains and warm, rocky hillsides all the best standard varieties can be produced in perfection. There are a number of small vineyards in every county. There are many vineyards of three to ten acres in Hartford, Middlesex, New Haven and Fairfield counties, mostly owned by Italians, and grown for wine-making purposes, although in recent years many of the selected grapes from these vineyards find their way into market, where they sell at much higher prices than any from outside the state. Concord, Worden and Niagara are varieties mostly grown for commercial and wine-making purposes, while almost the entire list of standard varieties can be and are grown in family vineyards.

Pears thrive and fruit well except on the lighter lands, and nearly every home-garden has from one to half a dozen trees. There are a few small commercial orchards in district No. 1, Bartlett and Clapp being most largely grown. At Hartford and the adjoining towns on the west side of the Connecticut River, the Bosc is produced in its highest perfection.

Cherries have been steadily failing in the state for twenty-five years. Not enough are grown for home supply. Newly planted trees soon die out, and there is a general discouragement. They seem to do best in the vicinity of Middletown and Meriden, and the few commercial plantings there are quite profitable.

Quinces are grown all over the state for home supply, but thrive best along the Sound shore, where there are a large number of small commercial orchards.

Strawberries are very largely grown, both for home and outside markets, mostly in medium matted rows, with an average yield of eighty to ninety bushels an acre. Some cultivators, who follow the hill system or grow in narrow, thinly matted rows, secure 150 or more bushels an acre. In recent years some of the heavy wet hilltop lands in Hartford and Tolland counties have been cleared of stones and are producing late in the season heavy crops of extra-fine strawberries that in 1914 supplied the Hartford market with the very best of the whole year and it is reported that the returns to the growers were from $600 to $800 an acre.

A number of the berry farmers have systems of irrigation which add greatly to the surety of the crop, besides increasing the size and appearance of the fruit. The rolling character of the country and vast number of small streams abundantly supplied with water make it possible, at moderate expense, to irrigate many thousands of acres in this state, and the time is not far distant when the streams of Connecticut will be more valuable to her horticulturists than they ever were to her manufacturers in the old days of many small factories and water-wheels.

Almost from the earliest settlement, small local nurseries have abounded in the state and today number forty-one, with three quite extensive ones in Hartford, New Haven and Fairfield counties. At Cromwell, Middlesex County, is a floricultural establishment which, with one exception, has the largest area under glass of any such establishment in America, —some thirty acres,—and surpasses all others in the annual production of superb roses.

The late Judge A. J. Coe, of Meriden, was one of the first men in America to take up the new chestnut culture by the importation of the best foreign varieties and the selection of the best natives and their crosses. He began the grafting on native sprouts and seedlings, and fifteen to twenty years ago stimulated a general chestnut grafting, so that a number of chestnut orchards were being established on land too rough for cultivation, yet strong in its ability to grow the chestnut tree and nuts to perfection; but the chestnut blight of recent years is playing such havoc with all chestnut trees that for the present no further developments can be expected.

At Wethersfield, in Hartford County, Orange and Milford, in New Haven County, and Southport, in Fairfield County, are many farms devoted to seed-growing. Onion seed and sweet corn are the great specialities, but a great variety of other seeds are also grown, especially at Wethersfield and Orange.

Market-gardening is conducted extensively by specialists near all large towns and cities, while, with so many markets always close at hand, vegetables and fruits are sold in moderate quantities from nearly every farm. The largest market-garden farm is at New Haven, where over 400 acres are under annual cultivation with vegetables and small-fruits. Twenty years ago at Southport, Fairfield and Westport, there were many farms, both large and small, devoted entirely to the production of onions. "Southport onions" were famous for fine appearance and quality, and nowhere in America was the annual yield so great or price received so high as in this district. Marketing was done in sailing vessels, direct from the farms to the dock markets in New York, where the onions were sold direct to retail dealers, boat captains acting as salesmen without commission for the sake of carrying the freight. For many years the net returns an acre were the greatest of any in the state. Being along the Sound shore and only fifty miles from New York, these valuable farm lands have in recent years been bought up for summer residents' property at $2,000 to $8,000 an acre, causing an entire abandonment of the once-prosperous onion business.

Trolley freight lines are widely extended through many farming sections of the state, and, running express cars at certain hours of the day with freight movements at night, they are growing to be a factor in the distribution of horticultural products.

Of the persons not now living who have had marked influence on the development of Connecticut horticulture may be mentioned: Theodore S. Gold, of West Cornwall; P. M. Augur, of Middlefield; Edwin Hoyt, of New Canaan; Richard Van Densen, of Enfield; A. J. Coe, of Meriden; Dr. Gurdon Russell, of Hartford; Albert Day, of Brooklyn; J. M. Hubbard, of Middletown; A. C. Sternburg, of West Hartford; John B. Smith, of New Britain; James B. Olcott, of Manchester; Miss Emily Moseley, of Glastonbury; and Mrs. John P. Bacon, of Danbury. Gold, Augur, Hoyt, Coe and Van Deusen were fountain-heads of horticultural knowledge in regard to varieties of fruits and their adaptability to different sections at the time of the commercial awakening in the seventies and early eighties of the last century; while Miss Moseley might be said to have been the mother of the great commercial horticultural industries that center about Glastonbury, in Hartford County, and reaching out into Tolland and Middlesex counties, while the influence of Augur, Coe and Hubbard are clearly shown in the large orchard interests now centered about Middlefield and Wallingford. Gold and Hoyt had a wider influence the whole state over, and their works live after them in nearly every rural home at the present time.

Public-service agencies for horticulture.

The State Agricultural College at Storrs, in Tolland County, and the Connecticut Agricultural Experiment Station at New Haven, are the only two public-service agencies doing any work along horticultural lines. While the Experiment Station at New Haven has no horticulturist under that name, it has a botanist who devotes his time to a study of the diseases of all farm crops and the means of combating them, and can also give advice regarding the pruning, grafting and general care of orchards. An entomologist does the same work for insect pests that the botanist does for fungous diseases. The Station inspects yearly all nurseries in the state. There is a specialist on market-gardening and a plant-breeder. There have recently been issued three or four horticultural bulletins, a spray calendar and a short bulletin of specific directions for treatment of orchards, and two or more within the year on insect pests.

There is a school of horticulture at Hartford, and horticulture is taught in connection with agriculture in many of the high-schools.

The Connecticut Pomological Society, organized some thirty years ago, is a prominent feature in the lively fruit interests of the state, and at the present time has a paying membership of nearly a thousand members, making it the largest society in proportion to population of any state in the Union.

Statistics (*Thirteenth Census*).

The approximate land area according to the 1910 census is 3,084,800 acres. Of this, 70.9 per cent or 2,185,788 acres are in farms. The land in farms that is improved is 988,252 acres, or 45.2 per cent; the land that is in woodland, 757,743 acres, and other unimproved land in farms, 439,793 acres. The number of all the farms in the state in 1910 was 26,815. Their average acreage at that time was 81.5. [The total area of Connecticut is 4,965 square miles.]

The leading agricultural crops are cereals, hay and forage, tobacco, and forest products of the farms. The acreage in cereals in 1909 was 74,083, showing an increase of only 2,051 acres over that of 1899. The value of the cereals in 1909 was $2,039,211 which was 9.1 per cent of the total value of all crops. The acreage of hay and forage in 1909 was 401,322, a decrease of 16.1 per cent from the acreage in 1899. The value of the hay and forage in 1909 was $7,224,500, which was 32.1 per cent of the total value of all crops. Tobacco increased in acreage 58.5 per cent during the ten-year period. The acreage in 1899 was 10,119; in 1909, 16,042. The value of the tobacco products in 1909 was $4,415,948 or 19.6 per cent of the total value of all crops. The value of the forest products from the farms in 1909 was $1,861,853; in 1899, $1,275,720.

The leading horticultural crops are potatoes and other vegetables, fruits and nuts, and flowers and plants and nursery products. Small-fruits are also of considerable importance. The acreage in potatoes has been changing constantly. In 1879 there were nearly 28,000 acres; there was a decrease of nearly 5,000 acres in 1889; an increase during the next decade, and a decline of over 3,000 acres between 1889 and 1909, leaving the acreage for 1909, 23,959. This acreage produced 2,684,414 bushels of potatoes, valued at $1,882,197. Other vegetables increased in acreage 31.6 per cent from 1889 to 1909. The acreage in 1889 was 12,349; in 1909, 16,250. The value of these vegetable products in 1909 was $1,965,635. The total value of fruits and nuts in 1909 was $1,375,699; that of flowers, plants and nursery products, $1,308,937. Small-fruits were also produced to the value of $316,752, although the acreage decreased from 1,987 in 1899 to 1,597 in 1910.

More than four-fifths of the quantity of orchard fruits produced in 1909 were contributed by the apple. Peaches, nectarines and pears produced most of the remainder. The production of apples in 1909 was 1,540,996 bushels, valued at $833,168; that of peaches and nectarines 269,900 bushels, valued at $417,598; that of pears 41,322 bushels, valued at $41,652. The other orchard fruits of lesser importance, their production and value in 1909 follow: plums and prunes, 13,663 bushels, valued at $19,419; cherries, 3,617 bushels, valued at $8,164; quinces, 4,627 bushels, valued at $7,027.

In 1910, there were 107,054 grape-vines of bearing age in Connecticut and 61,670 vines not of bearing age. The grapes produced amounted to 1,317,682 pounds, valued at $43,523.

The nuts of most importance in 1909 were the hickory-nuts and black walnuts. The number of hickory-nut trees of bearing age in 1910 was 3,792; those not of bearing age 5,385. The production was 64,124 pounds, valued at $2,656. The number of black walnut trees of bearing age in 1910 was 3,188; those not of bearing age 2,636. The quantity produced was 45,304 pounds, valued at $1,856.

Strawberries were by far the most important of the small-fruits grown in Connecticut, with raspberries and loganberries ranking next. The acreage of strawberries in 1909 was 993, as compared with 971 in 1899. The production was 3,016,295 quarts, valued at $235,648. The acreage of raspberries and loganberries in 1909 was 289 acres and the production 384,256 quarts, valued at $46,618. The acreage, production, and value of the other small-fruits follow: 128 acres of blackberries and dewberries, producing 192,752 quarts, valued at $16,869; 123 acres of cranberries, producing 145,408 quarts, valued at $9,555; 54 acres of currants, producing 74,488 quarts, valued at $7,056, and 9 acres of gooseberries, producing 9,023 quarts, valued at $878.

Aside from potatoes, discussed above, the more important vegetables, their acreage, and value in 1909 were as follows: 165 acres of asparagus, valued at $31,685; 167 acres of green beans, valued at $21,426; 733 acres of cabbage, value of which was $93,796; 159 acres of cantaloupes and muskmelons, the value of whose product was $25,898; 185 acres of celery, the value of the product being $55,142; 2,142 acres of sweet corn, the product valued at $137,083; 282 acres of onions, the value of the product being $38,156; 232 acres of green peas, the product valued at $24,382; 85 acres of spinach, the product being valued at $11,270; 621 acres of tomatoes, the product valued at $115,654; and 742 acres of turnips, whose product was valued at $40,968. Other vegetables grown were carrots, cauliflower, cucumbers, lettuce, green peppers, and watermelons.

In 1909, there were 560 acres occupied by flower and plant establishments as compared with 187 acres in 1899, an increase of 199.5 per cent. The area under glass in 1909 was 2,849,481 square feet, of which 2,636,063 were covered by greenhouses and 213,418 by sashes and frames. The total value of the flowers and plants in 1909 was $1,047,431.

The acreage occupied by nursery establishments increased from 605 acres in 1899 to 770 in 1909, an increase of 27.3 per cent. The total value of the nursery products in 1909 was $261,506. J. H. Hale.

MIDDLE ATLANTIC STATES.

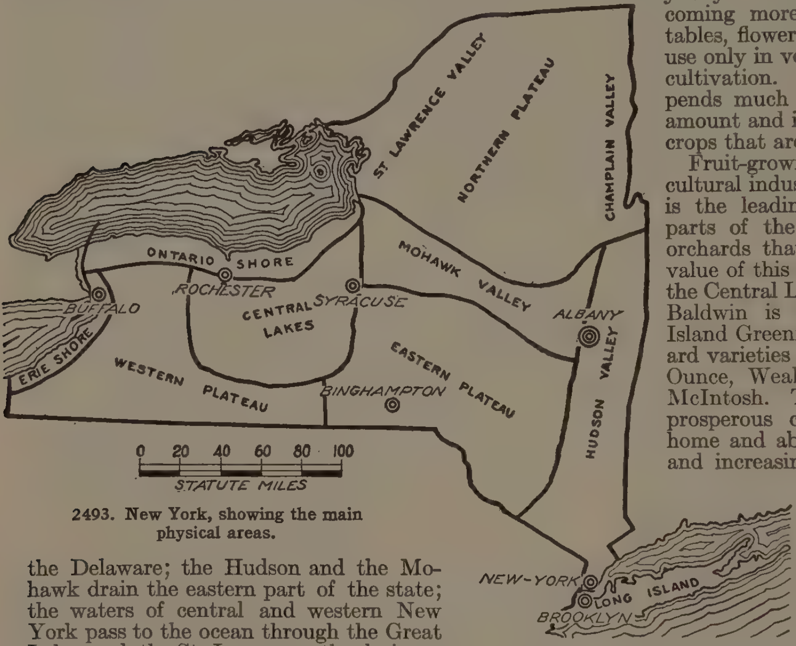
New York.

By virtue of its many substantial interests in horticulture, New York (Fig. 2493) is preëminent in this division of agriculture among the states of the Union. Thus, New York ranks first or takes a high place in fruit-growing, truck- and vegetable-growing, the production of nursery stock, the growing of cut-flowers, and in the plant and seed trade for vegetables and flowers. To these horticultural crops of first magnitude must be added the culture of nuts and of medicinal herbs. These industries, divided into a great number of distinct horticultural occupations,—for the tendency is to specialize more and more,—probably occupy the time of more workers than any other form of husbandry in the state, though the monetary value of the products is less than that of cereal and forage crops or of dairy products.

Horticultural industries in New York take high rank chiefly because climate and soil are so diverse and so favorable as to make possible one of the most highly specialized areas of American farming, but also because in its commercial supremacy the state supplies unusual markets for the products. Thus, to consider the last factor first, more than 9,000,000 persons live within the borders of New York. In the state there are five cities with more than 100,000 inhabitants, sixteen with 25,000 to 100,000, and one hundred and twenty-seven with from 2,500 to 25,000. This vast and prosperous population is most varied, consisting of many nationalities of all gradations of wealth and employed in nearly all the means of livelihood known to mankind, so that there are diverse demands as well as extensive markets for horticultural products.

New York ranks twenty-ninth in land area among the states and territories of the United States. The state extends east and west 412 miles, north and south 310 miles. About one-twentieth of the state, chiefly comprising Long Island, lies below an altitude of 100 feet, sixteen-twentieths between an elevation of 100 and 1,500 feet, while the mountainous regions of the Adirondacks and Catskills—three-twentieths of the total area—rise above 1,500 feet, the maximum altitude being above 5,000 feet in a few peaks in the Adirondacks. Excepting a small area in the southwestern part, the surface of the whole state shows, in a marked degree, the effects of the erosions, drifts and moraines of the Ice Age.

The state is drained by five water-systems. Excess water in a small area in the southeast passes through the Delaware; the Hudson and the Mohawk drain the eastern part of the state; the waters of central and western New York pass to the ocean through the Great Lakes and the St. Lawrence; the drainage of the southwestern part is through the Allegheny into the Mississippi system; while the Susquehanna carries the waters of south-central New York into Chesapeake Bay.



2493. New York, showing the main physical areas.

Through its physical features, the state is divided into nine areas, which are somewhat distinct in natural vegetation and more or less so in their agriculture and horticulture. The nine regions are shown in the accompanying map. The great specialization to be noted in the horticulture of New York is largely accounted for by the differences in the soil and climate of these natural divisions. They are outlined as follows: (1) The Long Island district, a lowland plain, for most part, covered with a thick moraine deposit, in which sand predominates; (2) the Hudson Valley region, lying on both sides of the Hudson River from its mouth north to Lake George—a region of very uneven topography and of several geological formations so varied in soils and climate that in it several special horticultural interests have developed; (3) the St. Lawrence and Champlain region, consisting of high and rolling lands and valleys, adjacent to the St. Lawrence River and Lake Champlain, to which may be added the tillable land in the Adirondack Mountains; (4) the broad and fertile valley of the Mohawk from Oneida Lake to the Hudson; (5) the eastern plateau, consisting of the Catskills and the highlands to the west, reaching to the basin of the Central Lakes; (6) the great basin, in which lie the Central or Finger Lakes, large and deep bodies of water having great influence on the climate of the region; (7) the shore of Lake Ontario, from the St. Lawrence to Niagara River, extending from the lake inland several miles to and including a high escarpment; (8) the Erie shore, a narrow plain from the Niagara River to Pennsylvania, bounded on the north by the lake and on the south by a high escarpment; (9) the western plateau, comprising the area west of the basin of the Central Lakes and south of the Erie and Ontario shore regions.

The rainfall in New York is exceedingly variable, owing to the uneven surface of the land. It varies greatly, in some cases, even within the limits of a county, the annual precipitation being sufficient for most crops in one part, and in another drought may yearly lie heavily on the land. Irrigation is coming more and more into favor for vegetables, flowers and small-fruits, but, as yet, is in use only in very limited areas and with intensive cultivation. Specialization in horticulture depends much upon the rainfall, both the total amount and its distribution helping to decide the crops that are grown in a region.

Fruit-growing is chief of the several horticultural industries in New York, and the apple is the leading fruit. Apples are grown in all parts of the state, but the great commercial orchards that give New York first rank in the value of this fruit are found in the Ontario shore, the Central Lake and the Hudson Valley regions. Baldwin is the leading variety, with Rhode Island Greening a distant second. Other standard varieties are Northern Spy, King, Twenty Ounce, Wealthy, Oldenburg, Ben Davis, and McIntosh. The apple industry is in a most prosperous condition, with large demands at home and abroad for boxed and barreled stock and increasing demands for fruit at the many evaporators and cider mills in the state. Apple-culture in New York has been greatly stimulated by the general tuning up in agriculture everywhere experienced during the past quarter-century. Good care is now the rule, while but a short time ago it was the exception.

The grape is second to the apple in importance in New York. Exclusive of California, New York produces nearly half of the grapes grown in the United States, and the yield in Chautauqua County alone is many times more than that of any other state excepting California. The industry is centered in the Erie shore, Central Lake and Hudson Valley regions. On the Erie shore, several times as many Concords are grown as all other varieties combined, the product going to the general markets and for the manufacture of grape-juice. About the Central Lakes, Catawba is the leading variety, a large part of the crop being used in the manufacture of wine and champagne. In the Hudson Valley, Concord, Delaware and Niagara are the leading varieties. The most striking feature in the grape industry at present is the rapid development in the manufacture of grape-juice, an industry which did not exist in 1900, but in which it is estimated more than 30,000 tons of grapes were used in 1915. Improvements in grape-culture have not kept pace with advances in growing other fruits, growers, in the main, cultivating too many acres from which they skim comparatively small returns.

The peach takes third place in commercial importance among the fruits of New York. The industry is most highly developed along the shores of Lake Ontario, from Oswego west, but is also in very thriving condition about the Central Lakes and in the valley of the Hudson. Some peaches are grown on the grape lands bordering Lake Erie. Elberta is the mainstay in all commercial orchards in New York, with no close second. Peach-growing is a fine art in the state, and nowhere can finer orchards of this fruit be found.

LXXI. North American horticulture.—A commercial cabbage field in New Jersey.

Pears are more or less grown in all the apple regions of New York. Bartlett and Seckel are the staple sorts, with Bosc, Anjou, and Winter Nelis largely grown. While New York ranks first among the states of the Union in number of trees and value of product, yet pear-growing is a great risk because of the blight which few attempt to control and which annually takes tremendous toll.

Increased plantings of cherries in recent years give this fruit greater value than the plum, which long held higher commercial rank. Montmorency is the leading sour cherry. Early Richmond and English Morello are standard kinds. These are grown wherever the apple thrives. By far the largest part of the sour cherry crop goes to the canneries. Napoleon, Windsor, Schmidt, Governor Wood, and Black Tartarian are the sweet sorts most commonly grown, the product going almost wholly to fresh-fruit markets. Sweet cherries are planted only in the peach regions. Cherry-growing in New York, as elsewhere, has many ups and downs, sweet cherries being, possibly, more at the mercy of the seasons than other fruits, and both sweets and sours having to weather many depressions in prices.

The leading variety of plum is Bradshaw, with Reine Claude, Italian Prune, German Prune, Lombard, Shropshire Damson, and Grand Duke following in order of importance. The plum industry is almost wholly confined to the Ontario shore and Central Lakes regions. Abundance and Burbank, Japanese sorts, are widely planted and give general satisfaction. Native plums, even at the best, are so inferior to the domestica sorts that they are seldom planted. The development of rapid transportation and refrigerator service has enabled Pacific coast growers so to compete with New York that plum-growing seems now to be on a decrease in the state, though recent turns in the markets indicate increasing demands for New York plums, which are better flavored because there is not the need to pick before fully mature for shipment.

One-fourth of all the quinces grown in the United States come from New York. Orange is the standard variety. Apricots thrive in the peach lands of the state, but spring frosts take such heavy toll and the curculio is so aggressive that this fruit is seldom profitably grown.

New York stands first in rank in the value of small-fruit products, but in acreage falls below New Jersey. Small-fruits, excepting cranberries, the culture of which is confined to Long Island, are grown in all parts of the state. Black raspberries are largely grown in the Central Lakes region for evaporation, the annual output ranging from 1,200 to 1,500 tons. Strawberry-growing assumes large proportions.

Several factors greatly favor truck- and vegetable-growing in New York; as, proximity to markets, many means of transportation, the cheapness of labor (largely performed by women and children), the demands of the many canneries, and a large acreage of suitable soil. Long Island is the region of highest specialization in vegetable-growing, most of the cultivated land there being devoted to the culture of truck and seed crops; but vegetables are everywhere grown commercially, the industry becoming especially prominent on the many muck formations in various parts of the state. The vast quantity of truck is nearly all used within the state, much of it, however, being taken by the canneries, the product of which, of course, finds sale in considerable quantities outside of New York.

For nearly a century, western New York has been the center of the nursery trade in the United States. The trees and plants are grown in the Central Lakes and Ontario shore regions, but are distributed chiefly from Rochester, Geneva, and Dansville. The most significant thing in the recent development of the nursery business is the very great increase in the proportion of ornamentals. The nursery business has suffered greatly from San José scale in the years just passed, but this pest has now been brought under control.

New York is also the center of the flower and plant trade of the United States. The floricultural and forcing interests are somewhat localized, though near every city and large town there are floral and forcing establishments. No doubt the greenhouse industry is most highly developed on Long Island, where roses, carnations and flowers for the retail trade are grown. Violet-growing is a thriving business at Rhinebeck on the Hudson. Vegetable-forcing thrives in and about Rochester. Large quantities of bulbs are grown on Long Island.

While there are but few commercial plantations of nuts in New York, the many trees about homes make a good showing for nut-growing in the state. In 1910, there were 164,333 bearing trees in New York; 51,239 not yet in bearing. Interest in nut-culture is yearly increasing.

Many vegetable and flower seeds are grown in New York, the state taking third place in the value of the product in 1909, the total value being $72,991. The principal seed crops grown are bush-bean, brussels sprouts, cabbage, sweet corn, cucumber, kale, onion, pea, turnip, asparagus, and the seeds of a considerable number of flowers, of which New York leads in the production of aster seeds.

Ginseng-culture is profitably carried on in several counties in the state. The value of the product in 1909 was $27,138, giving New York first place among the states of the Union.

The history of horticulture, as well as of countries, is that of its great men. So measured, New York has contributed much to American horticulture. The following is a partial roll-call of her eminent men in this profession not now living: C. L. Allen, seedsman, florist and author; Patrick Barry, nurseryman, editor, and author; Thomas Bridgeman, gardener, florist, seedsman, and author; E. S. Carman, editor and experimenter; John Craig, horticulturist and educator; A. J. Downing, landscape gardener and pomologist; Charles Downing, pomologist and author; George Ellwanger, nurseryman; Peter Henderson, florist, seedsman and author; F. M. Hexamer, nurseryman and editor; Jacob Moore, plant-breeder; Samuel B. Parsons, landscape gardener and author; William Prince (I), nurseryman; William Prince (II), nurseryman and author; William Robert Prince, nurseryman and author; A. M. Purdy, horticulturist and author; J. J. Thomas, pomologist and author; Grant Thorburn, seedsman; Luther Tucker, editor; Calvert Vaux, landscape gardener; and James Vick, seedsman and editor. See Volume III for biographies.

Public-service agencies for horticulture.

The State College of Agriculture was established in 1904 at Ithaca. Before this time, however, agriculture had been taught as a department in Cornell University. There are nineteen members of the horticultural staff.

Two experiment stations are doing research work in horticulture for the state. In 1879, the Cornell University Agricultural Experiment Station was organized at Ithaca. In 1888, this institution, one of the first of its kind in North America, was reorganized as a federal station. The New York Agricultural Experiment Station, located at Geneva, was established in 1882, and is supported by the state. Both stations give special attention to horticultural problems.

Horticultural education is provided for in a number of high-schools in the state; in secondary schools of agriculture at Alfred, Canton, and Morrisville.

Extension work in horticulture is also carried on in the state, through schools, farmers' institutes, and the like.

The various horticultural interests are nearly all organized into trade or educational societies, the time having long since passed when all could be represented in one organization. The first of these societies was the New York Horticultural Society, founded in New York City in 1818, long since extinct, probably the first organization of the kind in North America. In 1829 the Albany Horticultural Society was organized, but was short-lived. February 27, 1855, the Western New York Horticultural Society, now the oldest such society in the state, was organized, with headquarters at Rochester. February 27, 28, 1910, the New York State Fruit-Growers' Association was organized at Syracuse. The two societies named last have larger membership lists than any similar organization in North America. The nurserymen of the state have long had a trade organization, and the vegetable-growers are represented by the New York State Vegetable-Growers' Association, founded in 1913.

The State Department of Agriculture, at Albany, provides inspection service to control insects, diseases, fruit-grading, and fertilizers.

Statistics (*Thirteenth Census*).

The approximate land area in 1910 was 30,498,560 acres. The amount of this area that was in farm land in 1910 was 22,030,367 acres. Of this land in farms, 14,844,039 acres were improved; 4,436,145 were woodland; and the unimproved land in farms numbered 2,750,183 acres. The number of all the farms in 1910 was 215,597, and the average acreage a farm was 102.2. [The total area of New York is 49,204 square miles].

The leading agricultural crops are cereals, hay and forage, and forest products. In 1909, the acreage of cereals was 2,602,461, as compared with 3,125,077 in 1899, and the value of the cereals in 1909 was $43,099,988. Hay and forage decreased in acreage from 5,154,965, in 1899, to 5,043,373 in 1909, a decrease of 2.2 per cent. The value of hay and forage in 1909 was $77,360,645. The value of the forest products of the farms in 1909 was $10,365,651, as compared with $7,671,108 in 1899, showing an increase in value of 35 per cent.

Horticultural crops grown in New York are fruits and nuts, potatoes and other vegetables, small-fruits, flowers and plants, and nursery products. The value of the fruits and nuts in 1909 was $22,024,996, as compared with $13,377,105 in 1899, showing an increase in value of 64.6 per cent. The acreage of potatoes in 1909 was 394,319, as compared with 395,640 in 1899, and the value of the potatoes produced in 1909 was $20,338,766. Excluding potatoes, the acreage of other vegetables increased from 144,318, in 1899, to 175,402 in 1909, an increase of 21.5 per cent, and their value in 1909 was $15,963,384. The acreage of small-fruits in 1909 was 22,496, as compared with 25,051 in 1899, a decrease of 10.2 per cent, and their value in 1909 was $2,875,495. Flowers and plants and nursery products increased in acreage from 9,734, in 1899, to 11,659 in 1909, an increase of 19.8 per cent, and their value was $7,899,906.

The total quantity of orchard-fruits produced in 1909 was 29,456,291 bushels, valued at $17,988,894. Apples contributed about six-sevenths of this quantity, there being produced in 1909, 25,409,324 bushels, valued at $13,343,028. The number of apple trees of bearing age in 1910 numbered 11,248,203; those not of bearing age numbered 2,828,515. Peach and nectarine trees of bearing age in 1910 numbered 2,457,187; those not of bearing age, 2,216,907, and the production in 1909 was 1,736,483 bushels, valued at $2,014,088. Pear trees of bearing age in 1910 numbered 2,141,596; those not of bearing age, 1,502,661, and the production in 1909 was 1,343,089 bushels, valued at $1,418,218. Other orchard-fruits produced in 1909 were: 553,522 bushels of plums and prunes, valued at $519,192; 271,597 bushels of cherries, valued at $544,508; 132,451 bushels of quinces, valued at $135,345; and 9,805 bushels of apricots, valued at $14,490.

The total production of nuts in 1909 was 2,773,858 pounds, valued at $74,420. The more important productions of the various nuts were 286,227 pounds of chestnuts, valued at $23,589; 1,519,279 pounds of butternuts, valued at $21,631; 487,768 pounds of hickory-nuts, valued at $16,742; 465,918 pounds of black walnuts, valued at $11,485; and 9,346 pounds of Persian or English walnuts, valued at $858.

The number of grape-vines of bearing age in 1910 was 31,802,097; those not of bearing age, 3,801,800. The production of grapes in 1909 was 253,006,361 pounds, valued at $3,961,677, thus forming an important industry.

Of the small-fruits grown in New York, strawberries, raspberries and loganberries are the most important, with currants ranking next. The acreage of strawberries decreased from 7,311, in 1899, to 6,382 in 1909, when the production was 15,945,863 quarts, valued at $1,187,410. Raspberries and loganberries decreased in acreage from 12,376, in 1899, to 11,057 in 1909, when the production was 14,751,940 quarts, valued at $1,168,062. Currants decreased in acreage from 2,594, in 1899, to 2,557 in 1909, when the production was 3,982,389 quarts, valued at $264,051. The production of other small-fruits in 1909 was 2,509,851 quarts of blackberries and dewberries, valued at $210,986; 331,135 quarts of gooseberries, valued at $23,427; and 327,370 quarts of cranberries, valued at $20,743.

The value of vegetables, produced in 1909, excluding the potato, was $15,963,384, not exceeded by any other state in the United States in value of vegetable products. The leading vegetables grown in 1909 were 35,269 acres of cabbage, valued at $2,335,999; 2,926 acres of celery, valued at $946,424; 23,739 acres of sweet corn, valued at $942,023; 5,558 acres of onions, valued at $954,610; 16,992 acres of green peas, valued at $815,256; 8,636 acres of tomatoes, valued at $775,803. Other important vegetables grown in 1909 were asparagus, green beans, beets, carrots, cauliflower, lettuce and turnips, spinach, rhubarb, radishes, parsnips, horse-radish, cucumbers, cantaloupes, and muskmelons.

New York ranks first among the states in the production of flowers and plants. The acreage devoted to this industry increased from 1,496, in 1899, to 2,979 in 1909. The area under glass in 1909 was 15,066,587 square feet, of which 13,876,857 were covered by greenhouses and 1,189,730 were covered by sashes and frames. The value of the flowers and plants produced in 1909 was $5,148,949, as compared with $2,867,673 in 1899.

New York also ranks first in the value of nursery products produced. The acreage devoted to this industry increased from 8,238, in 1899, to 8,680 in 1909. The value of the nursery products in 1909 was $2,750,957, as compared with $1,642,107 in 1899.

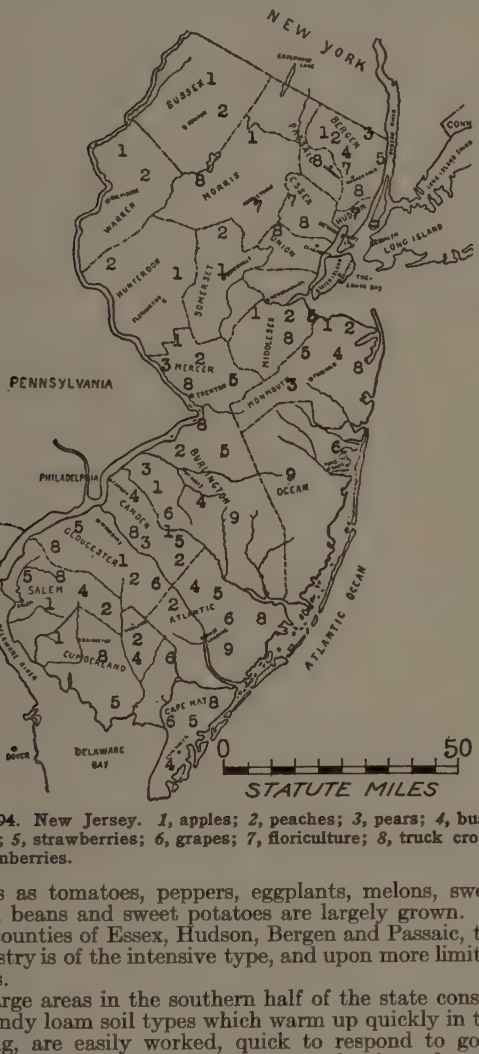
U. P. Hedrick.

New Jersey.

Considering its area, New Jersey (Fig. 2494) is wonderfully favored in its range of soil and climatic conditions. In the northern part, the land is rolling and hilly, with areas rich in lime and mineral plant-food, and with climatic conditions suitable for such apples as the Baldwin and Greening. South of this hilly area is a plains region crossing the counties of Somerset and Hunterdon, where varieties requiring a little longer season should be grown. The southern half of the state has soil types varying from clay loams to the lightest sand, offering ideal conditions for the growing of all crops from the sweet potato to celery, corn and grass, and from the cranberry to the peach. The southern counties have conditions resembling those of the Delaware and Maryland peninsula and early truck crops can be grown to good advantage. The northern counties have conditions resembling parts of New York and New England.

Situated between the greatest markets on the Atlantic seaboard, and near numerous industrial centers, the lands of the state are intensively cultivated to yield a great variety of horticultural products.

Vegetable and truck crops are produced to exceed a value of $7,000,000 annually, exclusive of potatoes and sweet potatoes. In the southern counties, the industry is conducted upon an extensive trucking basis, and such crops as tomatoes, peppers, eggplants, melons, sweet corn, beans and sweet potatoes are largely grown. In the counties of Essex, Hudson, Bergen and Passaic, the industry is of the intensive type, and upon more limited areas.



2494. New Jersey. *1*, apples; *2*, peaches; *3*, pears; *4*, bush-fruits; *5*, strawberries; *6*, grapes; *7*, floriculture; *8*, truck crops; *9*, cranberries.

Large areas in the southern half of the state consist of sandy loam soil types which warm up quickly in the spring, are easily worked, quick to respond to good management and ideal for the production of early vegetables upon an extensive scale. An extensive trucking area extends from just south of Bordentown along the Delaware River to Palmyra. Early peas, beans, sweet corn, rhubarb, asparagus, and other vegetables are grown in succession and companion cropping systems. Another characteristic of this section is the large number of young peach, apple and cherry orchards intercropped with vegetables. Another large trucking area centers about Moorestown. Fruit and vegetables are the important crops upon many farms in this region.

Swedesboro is the center of the great tomato and sweet potato section in Gloucester County, and is one of the leading shipping stations for vegetables in the United States. From fifty to sixty carloads of tomatoes is a common daily shipment at the height of the season, and during July, 1912, more than 400,000 crates were shipped by rail to distant points, while large quantities were sold in Philadelphia and other nearby markets. One day's shipment of tomatoes from Swedesboro in 1910 comprised 36,000 crates and 25,000 baskets. The industry about Swedesboro has become a specialty in the production of early tomatoes to be placed on the market after the southern crop has been shipped. Earliana is the variety almost exclusively grown.

Tomatoes are also grown very extensively outside the Swedesboro district. The reported acreage in New Jersey in 1910 was about one-eighth the reported acreage of the entire country and the value of the New Jersey crop was estimated to be about one-sixth the value of the crop in the United States. New Jersey tomatoes are consumed in large quantities in the smaller towns and cities of the state as well as at the large seashore resorts. Soil conditions are favorable to the production of tomatoes at no great distance from these local markets and they are kept well supplied throughout the season. Along the Delaware River, tomatoes are shipped by boat to Wilmington, Baltimore and Philadelphia. Refrigerator cars are employed for distant shipments by rail to such points as Boston, Pittsburgh, and Chicago. A few shipments are even made to markets as far south as Florida.

Another prominent feature of the tomato industry is the canning business. Large areas of tomatoes are grown under contract for the canning trade. Prices for canning tomatoes commonly range from $8 to $10 a ton. The medium- and late-crop tomatoes are the ones used for canning, and such varieties as Bonny Best, Cumberland, Stone, and Greater Baltimore are the most popular. The plant of the Campbell Soup Company is at Camden, and vast quantities of tomatoes are contracted for and purchased throughout southern New Jersey. At the height of the season, long lines of market wagons loaded with 175 to 250 baskets of tomatoes can be seen going into Camden.

Tomatoes are not the only vegetables that are canned in the state. More than fifty canning factories were in operation in central and southern New Jersey in 1912, and peas, beans, beets, sweet potatoes, and other vegetables are canned annually. The acreage and value of many vegetable crops are large in the state.

The floricultural interests of the state are great and products amounting to more than $2,850,000, are produced annually. The center of this industry is in Morris, Essex and Hudson counties, but with large individual plants at Riverton and other points.

Orchard-fruits are produced at an annual value exceeding $1,975,000. The introduction of the San José scale caused great damage to the orchards about 1900, but the culture of these fruits is now progressing as never before. Monmouth, Burlington and Gloucester counties now lead in the production of apples. Such varieties as Yellow Transparent, Duchess of Oldenburg, Williams, Gravenstein, English Codlin, Starr, Wealthy, Twenty Ounce, McIntosh, Grimes, Stayman, Baldwin, Rome, Delicious and Arkansas (Paragon) comprise a good commercial list for the state. The summer and fall varieties prove to be as profitable as the winter apples, and are being planted liberally.

Peach-production is increasing very rapidly upon modern lines. About the year 1900 the counties in the northwestern part of the state were leaders, but at present Burlington and Monmouth are assuming the lead with Gloucester, Atlantic and Cumberland making rapid strides. Annual plantings of 20,000 to 30,000 trees are being made about small centers where only an average of 4,000 to 8,000 trees were planted in 1908 and 1909. There has been a marked change in the popularity of varieties also. At one time Mountain Rose, Early Crawford and Reeves were leading commercial sorts, but today the list would be selected from such varieties as Greensboro, Carman, Lola, Hiley, Belle, Elberta, Frances, Iron Mountain and Krummel. Shipments were made in sixteen-quart baskets almost exclusively about 1900, but the Georgia carrier is now preferred for shipments by rail. The sixteen-quart and twenty-quart baskets are still used extensively where the fruit is hauled direct to the Philadelphia and local markets.

Pears are still grown in large quantities in Burlington, Gloucester, Camden and Monmouth counties, but apples and peaches have received more attention since the pear-blight appeared. In spite of this disease, however, the industry is holding its place. Such sorts as Bartlett, Seckel, Kieffer, Duchess and Lawrence are the most widely grown.

Plums are not being planted to any extent commercially. Most of this fruit is now produced in Bergen, Somerset and Morris counties.

The planting of sour cherries is on the increase, especially in Burlington and in counties south of it. Early Richmond and Montmorency are the most popular sorts.

Sweet cherries are planted to a limited extent only. Quinces are just beginning to receive attention commercially under modern methods and increased plantings are likely to be made each year.

The annual production of small-fruits holds nearly equal rank to that of the tree-fruits in New Jersey with a total area exceeding 24,000 acres. And of these the strawberry leads with an acreage exceeding 8,600 acres. Cumberland, Burlington and Atlantic counties lead in the production of this fruit.

The cranberry industry is the most extensive of any state in the Union. Over 9,000 acres are devoted to this crop. The features of the industry are the development of distinct varieties and the fertilizing and spraying of the bogs. This industry is centered in Burlington, Atlantic and Ocean counties.

Blackberries, dewberries and raspberries are extensively grown in all the southern counties of the state. The center of the industry is in Atlantic County about Hammonton. The Ranere (St. Regis) raspberry is said to have originated in this district. Ward is the most popular variety of blackberry, and Lucretia is the only dewberry grown to any extent. Currants and gooseberries are being planted in larger quantities, especially in Burlington, Monmouth, Camden and Bergen counties. Red Cross, Fay and Wilder are leading commercial currants, while Downing leads as a gooseberry.

The planting of vineyards is increasing. Large numbers of small vineyards are being set by Italian farmers in Atlantic, Cumberland and Gloucester counties. Vineyards of 100 acres or more in extent occur in Cumberland and Camden counties. The most popular varieties are Concord, Ives, Niagara, Diamond and Moore Early.

The motor-truck is becoming an important factor in New Jersey horticulture. Some fruit-growers and truckers are becoming independent of the railroads in getting their produce to market.

The following men did much to advance horticulture in New Jersey in early years: George Thurber, Passaic; E. Williams, Montclair; W. R. Ward, Lyons Farms; Joseph Ward, Lyons Farms; Patrick Quinn, Newark; Peter Henderson, Jersey City; Col. A. T. Pearson, Vineland; William Parry, Cinnaminson, and John Repp, Glassboro.

Public-service agencies for horticulture.

The land-grant college of New Jersey was established at New Brunswick in 1864 in connection with Rutgers College. There are now three men on the horticultural staff.

Both the College Station and the State Experiment Station are located in New Brunswick. The State Station is the only one conducting special horticultural investigations at the present time, and the staff consists of seven men. Much plant-breeding work with vegetables is being conducted at the College Experiment Station, which can be classed as either botanical or horticultural. Extensive peach investigations are conducted in different parts of the state but principally at Vineland where about 12 acres of land are leased by the Station. Eight bulletins have been issued relative to fruit-culture; thirteen to vegetable crops and one relative to both; thirty-six bulletins to insects injurious to fruits and vegetables; fourteen to diseases of fruits and vegetables, and one to both insects and diseases of fruits and vegetables. Five circulars and special bulletins have been issued in regard to fruit, three upon vegetable crops and ten upon insects and diseases affecting vegetable crops. One bulletin upon rose-culture is now ready for issue.

Three vocational schools have just been established in Atlantic County in which horticulture is taught. Horticulture is also taught in a few of the high-schools, especially at Freehold.

There is no provision made for horticulture in any state department at present. Extension work in horticulture is being conducted by one specialist and assistant in fruit-growing and one specialist in market-gardening.

Inspection of nursery stock for insects and diseases is in charge of the State Entomologist, and the State Plant Pathologist, who are both members of the Station staff.

The New Jersey State Horticultural Society has been an important factor in the progress of horticulture in New Jersey. This Society was organized August 17, 1875, at New Brunswick. George Thurber was elected as first president. A vegetable section was formed in December, 1914, in order to bring about coöperation between the trucking and fruit interests.

Statistics (Thirteenth Census).

The approximate land area of New Jersey in 1910 was 4,808,960 acres. The land in farms was 53.5 per cent of the land area, or 2,573,857 acres. Of this area in farms, 1,803,336 acres were improved land; 538,131 acres were in woodland; and 232,390 acres was other unimproved land in farms. The number of all the farms in 1910 was 33,487 and the average acreage to the farm 76.9. [The total area of the state is 8,224 square miles.]

The leading agricultural crops are cereals and hay and forage. The acreage devoted to cereals decreased from 588,853 in 1899 to 503,651 in 1909, when the value of the production was $9,797,937. Hay and forage decreased in acreage from 444,610 in 1899 to 401,315 in 1909, when the production was valued at $7,627,402. The value of the forest products of the farms in 1909 was $758,515, as compared with $469,055 in 1899.

Horticultural crops produced in New Jersey are fruits and nuts, small-fruits, vegetables including potatoes and sweet potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $2,115,321 as compared with $2,697,399 in 1899. Small-fruits decreased in acreage from 25,350 in 1899 to 24,069 in 1909, when 38,822,987 quarts were produced, valued at $1,954,125. In 1909 the total acreage of vegetables, including potatoes and sweet potatoes, was 181,722, and their value $14,073,467. Vegetables, excluding the potato and sweet potato, increased in acreage from 77,779 in 1899 to 86,227 in 1909, when the production was valued at $7,566,493. It is thus seen that the raising of vegetables is a very important industry in New Jersey, as 34.9 per cent of the total value of all crops in 1909 was produced by the vegetables, including potatoes. The raising of flowers and plants and nursery products is of considerable importance, the acreage having increased from 2,395 in 1899 to 3,603 in 1909, when the production was valued at $3,539,523.

The production of orchard fruits in New Jersey in 1909 was 2,372,358 bushels, valued at $1,975,044. Apples produced nearly three-fifths of this quantity, peaches and nectarines and pears most of the remainder. The production of apples in 1909 was 1,406,778 bushels, valued at $956,108. The number of apple trees of bearing age in 1910 was 1,053,626 and those not of bearing age 519,749. Peach and nectarine trees of bearing age in 1910 numbered 1,216,476; those not of bearing age, 1,363,632, and the production in 1909 was 441,440 bushels, valued at $652,771. The number of pear trees of bearing age in 1910 was 731,616; those not of bearing age, 238,401, and the production in 1909 was 463,290 bushels, valued at $254,582. Other fruits produced in 1909 were: 44,636 bushels of cherries, valued at $87,225; 9,594 bushels of plums and prunes, valued at $13,476; 6,442 bushels of quinces, valued at $10,583; and 178 bushels of apricots, valued at $299.

The production of grapes increased from 4,235,000 pounds in 1899 to 6,501,221 pounds in 1909, valued at $132,957. The grape-vines of bearing age in 1910 numbered 1,603,280; those not of bearing age, 558,945.

The total production of nuts in 1909 was 249,626 pounds, valued at $7,116. The production of the more important of the individual nuts was 151,828 pounds of black walnuts, valued at $2,766; 62,243 pounds of hickory-nuts, valued at $2,468; and 25,987 pounds of chestnuts, valued at $1,413.

Strawberries are the most important of the small-fruits grown in New Jersey, with cranberries second in importance. The acreage of strawberries decreased from 8,746 in 1899 to 8,684 in 1909, when the production was 18,767,473 quarts, valued at $929,108. The acreage of cranberries increased from 8,356 in 1899 to 9,030 in 1909, when the production was 12,072,288 quarts, valued at $504,026. The acreage of blackberries and dewberries decreased from 5,254 in 1899 to 4,332 in 1909, when the production was 5,456,789 quarts, valued at $313,480. Raspberries and loganberries decreased in acreage from 2,240 in 1899 to 1,744 in 1909, when the production was 2,143,877 quarts, valued at $178,579. The production of gooseberries in 1909 was 221,337 quarts, valued at $16,171; and that of currants 161,223 quarts, valued at $12,761.

The potato industry increased from an acreage of 52,896 in 1899 to 72,991 in 1909, when the production was 8,057,424 bushels, valued at $4,979,900. The sweet potato and yam acreage increased from 20,588 acres in 1899 to 22,504 in 1909, when the production was 3,186,499 bushels, valued at $1,527,074. Of the other vegetables produced in New Jersey in 1909, the more prominent were: 26,552 acres of tomatoes, valued at $2,131,973; 5,148 acres of asparagus, valued at $602,317; 10,442 acres of sweet corn, valued at $557,708; 4,864 acres of cabbage, valued at $368,454; 3,861 acres of cantaloupes and muskmelons, valued at $306,073; 3,740 acres of green beans, valued at $238,149; 4,912 acres of green peas, valued at $208,934; 621 acres of celery, valued at $201,735; 1,417 bushels of onions, valued at $171,344; and 2,226 acres of watermelons, valued at $137,584. Other vegetables produced were beets, carrots, cauliflower, cucumbers, eggplant, horse-radish, lettuce, parsley, parsnips, green peppers, pumpkins, radishes, rhubarb, spinach, squash and turnips.

The acreage devoted to the flower and plant industry increased from 613 in 1899 to 1,436 in 1909. The area under glass in 1909 was 8,840,511 square feet, of which 7,984,752 were covered by greenhouses and 855,759 by sashes and frames. The value of the flowers and plants produced in 1909 was $2,857,709.

Nursery products increased in acreage from 1,782 in 1899 to 2,167 in 1909, when the nursery products were valued at $681,814, as compared with $339,926 in 1899.

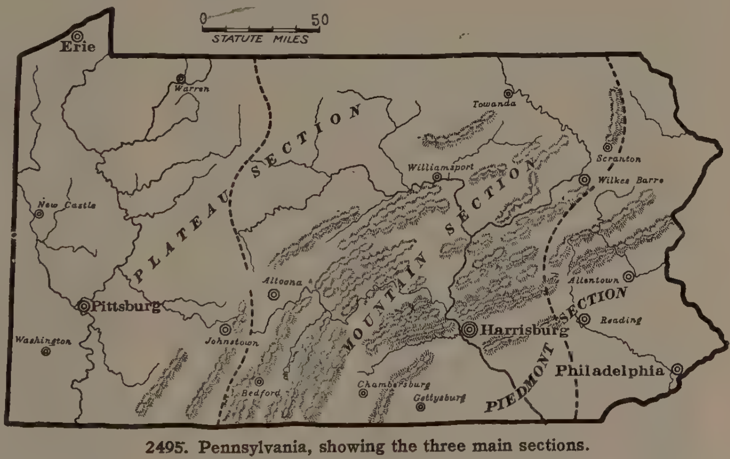
M. A. Blake.

Pennsylvania.

Pennsylvania (Fig. 2495) is the second state in the Union in population, although only the thirty-second in size. It is located between parallels 39° 40′ and 42° north, and in longitude between 75° and 80° 30′ west. It is roughly rectangular in shape, averaging 285.8 miles in length and 157.8 miles in width, about 65 per cent of its area being in farms. The large unfarmed area remaining is due chiefly to the fact that the entire Appalachian system swings diagonally across the state, leaving most of it rough and mountainous. It is also partly due to the great strength of the coal-mining and the gas, petroleum and lumbering industries, some of which, however, are now on the wane. In altitude, the state varies from practically sea-level in the Philadelphia section to a height of nearly 3,000 feet in the central mountain and plateau region, and then sinks again to about 600 feet above sea-level along the Lake Erie shore.

The precipitation varies considerably in different localities, owing largely to their relation to the adjacent mountains, but in general it is satisfactory. Towanda is in one of the lowest sections, with an annual average of only 34.6 inches. From this, the average rises to 38.2 inches at Erie and to 40.9 inches annually at Philadelphia. At Pittsburgh, State College and Harrisburg, the averages have been 36.2, 38.9, and 36.9 inches respectively, over observation periods ranging from twenty to sixty-three years. At State College, the extremes during the last thirty years have been 25.2 and 45.8 inches.

The annual temperatures also naturally vary considerably as a result of mountain or of water influences. At representative points in the state the records show the following averages over long periods: Erie, 48.8°; Pittsburgh, 52.7°; State College, 48.6°; Towanda, 47.8°; Harrisburg, 51.6°; and Philadelphia, 52°. Similarly the records show that the average growing season, or the average period between killing frosts, is especially variable, showing the great influence of altitude or of large bodies of water on the average length of the frost-free period.



2495. Pennsylvania, showing the three main sections.

Looking at the general surface of the state in greater detail, it is seen that it is divided into three great sections. The first of these lies east and south of the Blue Mountains, which run in a broad curving line from Franklin County around north of Harrisburg to the northern side of Northampton County. This section has a generally rolling to hilly topography, broken by a few irregular low mountain groups, of which the South Mountains, Welsh Mountains and the Reading Hills are most prominent. This was the region first settled, and it is now mostly under cultivation and contains probably the best lands of the state. It includes the small coastal plain region, the Piedmont plateau, and a part of the Limestone Valley and Alleghany Mountain provinces, the latter of which crops out in the low mountain groups referred to above.

The second section extends from the Blue Mountains to the Alleghany escarpment, which runs from Somerset County around west of Altoona, slightly north of Williamsport and on eastward in reduced form through Lackawanna and Wayne counties. In general form, this section is a large crescent, about 50 to 60 miles in width, and comprises about a fourth of the state. It consists of a numerous succession of parallel mountain ranges, derived from hard sandstones and separated by comparatively narrow valleys which have been carved out from shales or soft sandstones. It includes parts of the Alleghany Mountain, Limestone Valley, and glacial provinces. The broader valleys in this section, especially those of limestone origin, are fertile and well adapted to general farm crops, but the hills and mountain slopes are usually stony and more or less barren.

The third or plateau section lies west and north of the Alleghany escarpment and includes about 55 per cent of the area of the state. It consists of a much-dissected plateau, broken by occasional mountain ridges, and deeply scored by frequent streams or cañons, some of the latter being as much as 800 feet deep in the northern part, where the general elevation is greatest. Most of this area is distinctly mountainous in character. It has been very largely in forests, and much of it has been cleared so recently that but little has yet been accomplished toward its utilization along other lines. The soils of the DeKalb series are much the most extensive in this general region, though the Westmoreland, Upshur, and Berks soils are fairly prominent. The general location and adaptations of these and all other important soils in the state, are well given in a recent Bulletin, No. 132, by C. F. Shaw, from the Pennsylvania Station.

From the horticultural viewpoint, there is probably no state in the Union with greater possibilities than Pennsylvania. Its general location, large population, wide range of soils and almost unlimited choice of topography within relatively small areas, offer advantages that are very difficult to equal elsewhere. These advantages have only begun to be realized, however, and although the production is already large along many lines, it has generally been due to the large aggregate of relatively small growers producing for local markets, rather than to any large and well-managed commercial efforts. The present development, therefore, must be regarded only as a beginning.

In total value of horticultural products, Pennsylvania usually ranks third, being preceded by California and New York and followed by Michigan. In 1909, Michigan forged slightly ahead in total value of fruit, but even in that year the shortage in fruit was much more than made up by the difference in vegetables, flowers and nursery products, and with the latter included the state easily secured third place with a margin of more than $4,500,000.

Among the specific horticultural crops, apples are probably the most cosmopolitan, since they usually thrive in almost any part of the state where both local conditions and varieties have been properly selected. They contributed about five-sixths of the total orchard production in 1909. Both apples and peaches do especially well in proper locations over the entire Piedmont section of southeastern Pennsylvania, referred to above. They are also grown with special success on many of the foothills and more gentle slopes of the eastern and southern ranges of the Appalachian system. In Erie County, the narrow glacial lake area in the extreme northwestern part of the state is being rapidly developed for the production of grapes and peaches especially, with considerable commercial interest also in apples, cherries, plums and vegetables. This county is distinctly in the lead in horticultural products as a whole, and is followed in order by Lancaster and York, whose high totals are due chiefly to their large vegetable-production. In apples, however, the most intensive commercial area at present is the one in Adams County, although there are a number of other localities in the state where the natural advantages are fully as good, as shown by the marked success of individual orchards.

Many important varieties of fruits have originated in Pennsylvania, some of them now being grown widely. Among apples, the most important are as follows: York Imperial, Smokehouse, Rambo, Cornell (Fancy), Sweet Winesap, Smith (Cider), Jefferis, Ewalt (Walker Beauty), Major, Minkler, Winter Sweet Paradise, York Stripe, Winter Blush, Fallawater, Early Ripe, Doctor, Belmont, Strode (Birmingham), Wine, Cooper Market, Dickinson, Evening Party, Golden Spy, Krauser, and Lehigh (Greening). Altogether, Pennsylvania is credited with the origin of no less than 314 varieties of apples.

Among the pears, the following are the most important that have originated in Pennsylvania, viz., the Seckel, Tyson, Rutter, Brandywine, Kieffer, Garber and Ott. Of the plums, the most important of Pennsylvania origin are the Richland, Hulings, and Spaulding; of raspberries, the Cumberland, Philadelphia (purple-cane) and the Orange (a hybrid of *Rubus Idæus* and a native American species, originated by Dr. Brincklé); of blackberries, the Allen and Erie are most important; of strawberries, Brandywine, Cumberland, Glen Mary and Sharpless; of peaches, the Globe, Klondike, and Tippecanoe; of cherries, the Ida; of chestnuts, the Paragon, Bartram, Miller, Numbo, Corson, Comfort, and Styer; of Persian walnuts, the Rush.

The opportunities for commercial vegetable-production are especially good in Pennsylvania because of its unusual number of good-sized cities and towns, in which the people are chiefly engaged in manufacturing or other industrial pursuits. In fact Pennsylvania contains fifty-eight cities of more than 10,000 inhabitants, which is seven more than any other state. This has developed large local production of vegetables around these cities in all parts of the state. In addition, there are considerable areas producing cabbage and other vegetables for shipment,—notably in Lancaster, York and Erie counties.

Another vegetable area of very intensive production has been developed on the muck soils around Wellsboro in Tioga County. In this place a total of about 280 to 300 acres of regular mucklands are in active service, besides some of the more fertile adjacent loams, which have sufficient fiber to produce good crops for a few years in favorable seasons. The annual production is estimated to bring in to the growers from $125,000 to $150,000, depending on season and prices. Celery and head lettuce are the only crops produced to any extent, and only one variety of each is used,—the Golden Self-blanching celery and the Big Boston lettuce. The former constitutes about 70 per cent of the crop. The crop is marketed in carlots, all of the lettuce and most of the celery going to Philadelphia.

Some of the leading varieties of vegetables that have apparently originated in Pennsylvania are as follows: bean, Burpee Bush Lima,—the fore-runner of all the large-podded bush limas, which was found as a chance variation in a field of Large White limas on the farm of Asa Palmer near Kennett Square, in 1883; celery, Fordhook Emperor; beet, Burpee Extra Early, Bastian Extra Early Turnip, and Bastian Half-long Turnip; cabbage, Burpee Surehead and Houser. The latter is said to be the result of a cross between Flat Dutch and Fottler Brunswick. It was developed by George Houser about 1890 and introduced by the Holmes Seed Company in 1900; tomato, Chalk Jewel and Bonny Best. The former is the result of a cross between Hubbard Curled Leaf and Livingston Perfection, made by James Chalk of Norristown, in 1889. Bonny Best is said to be a selection of Chalk Jewel and was introduced by W. P. Stokes, in 1908.

The floricultural and special-crop interests have been developed to an unusual extent in the general vicinity of Pennsylvania. Some fifteen or twenty years ago, the carnation industry had developed to such an extent, especially around Kennett Square, that it had become known as the "carnation belt." There was also an unusual development of mushroom-production in the same district. Both industries then dropped back very materially for a time, but in the last few years the production of carnations, and especially of sweet peas, has come in again. The special carnation area has also extended and is now being developed to a large extent north of Philadelphia as far out as Hatboro, and even up to Lancaster. The latter city is becoming a carnation center, and is also producing considerable quantities of sweet peas, of which the leading varieties in this general section are of the Spencer class.

All the large growers in and around Philadelphia are also engaged in rose-production with a few fairly large places that are specializing in them. The American Beauty is the leading variety, especially in the Chestnut Hill district, which has the reputation of producing this rose in the highest state of perfection. The state as a whole, is credited with 1,331 floricultural establishments in 1909 with a value of $3,803,000. It was excelled only by New York in this respect.

The nursery and seed interests around Philadelphia are also noteworthy. The seed-farms of Burpee & Company near Doylestown, and of the D. Landreth Seed Company near Bristol are among the largest in the country,—the former involving about 450 acres and the latter about 600 acres. The latter seed-house was established in Philadelphia in 1784. In nurseries, for both fruit and ornamental stock, there is now a total of more than 2,600 acres within a few miles of Philadelphia,—in Chester, Bucks, Montgomery, and Philadelphia counties,—which makes this one of the leading centers of the country for these industries.

In parks and city improvement systems, Pennsylvania is showing an unusual degree of interest. The oldest and largest rural park in the state is Fairmount in Philadelphia, which now has 3,448 acres and is being extended annually, part of it at great cost. It now includes the old Bartram Garden, established in 1728, the first attempt in the United States to gather trees for study purposes. The Centennial Exposition of 1876 was located in this park. Other smaller areas are annually being acquired for rural or community parks in various sections of the city. Pittsburgh has two rural parks, Schenley and Highland, and also the Alleghany Parks formerly known as the Commons. Especially notable park and civic improvements have been made in Harrisburg since 1902. The parking of the Susquehanna River front, the flood-prevention, extension of Reservoir Hill Park, establishment of playgrounds under supervision, the extension of Capitol Park, and the city control of shade trees are worthy of emulation by larger cities.

Among those now deceased who have rendered important service in one or more phases of horticulture, the following may be mentioned: John Bartram (volume III, page 1564), the founder of the Bartram Garden; John Adlum (page 1563), a native of York County, who first called special attention to the Catawba grape; William D. Brincklé (page 1566), of Philadelphia, the second president of the American Pomological Society, experimenter with raspberries, strawberries, and pears, originator of the Orange raspberry in 1843, which is even yet the quality ideal in this fruit; Henry A. Dreer (page 1573), one of the pioneer seedsmen and nurserymen especially along ornamental lines; Thomas Meehan (page 1587), nurseryman and extensive writer along floricultural and landscape lines; W. G. Waring, nurseryman, fruit-grower, friend of Downing, and one of the first teachers of general horticulture in the College; Wm. A. Buckhout, and G. C. Butz (page 1568), botanists and horticulturists, long connected with the teaching staff of the College and state; and Gabriel Hiester (page 1580), fruit-grower, horticultural writer, long-time president of the State Horticultural Association.

Public-service agencies for horticulture.

The land-grant college of the state was opened for students in February, 1859, under the name of the "Farmers' High-School." This name was changed to "The Agricultural College of Pennsylvania" in May, 1862, and this again was changed to "The Pennsylvania State College" in 1874. It was accepted by the state as the land-grant college in 1863. There are now (in 1915) eleven men on the horticultural staff.

The Experiment Station is located at the College, and, including the Institute of Animal Nutrition, it involves a staff of eighty-eight persons. Thirty bulletins on horticultural subjects have been published by the Station, and twenty-one by the State Department of Agriculture, located at Harrisburg.

The School of Horticulture for Women at Ambler has a total of 90 acres of land, 20 acres being reserved for horticultural work. There are some thirteen agricultural high-schools in the state, giving more or less instruction in horticulture.

Some horticultural work, especially along the line of spraying and pruning demonstrations in connection with pest control, has been done for the past five or six years by the State Department of Agriculture at Harrisburg. The nursery inspection for the state is also done there, while the plant-disease work is in charge of the College. Definite inspection of the grading of fruit has not been provided for as yet.

A considerable amount of extension work in horticulture is done by the College staff, working especially through the state and county horticultural organizations. The experimental orchards of apples and peaches maintained by the College in the various fruit-growing sections of the state may also be considered as an important part of the extension work in the state.

Other associations devoted to horticultural interests are the State Horticultural Association of Pennsylvania, the Pennsylvania Horticultural Society (devoted chiefly to floricultural interests) and Pennsylvania Nurserymen's Association.

Statistics (*Thirteenth Census*).

The approximate land-area in 1910 was 28,692,480 acres. The land in farms was 64.8 per cent of the land area or 18,586,832 acres. Of this land in farms, the improved land numbered 12,673,519 acres; the woodland 4,281,439 acres; and other unimproved land in farms 1,631,874 acres. The number of all the farms in the state was 219,295, and the average acreage a farm 84.8. [The total area of Pennsylvania is 45,126 square miles.]

The leading agricultural crops of Pennsylvania are cereals, hay and forage, and tobacco. The acreage devoted to cereals decreased from 4,738,195 in 1899 to 4,324,058 in 1909, when the production was valued at $70,348,726, which was 42.2 per cent of the total value of all crops. Hay and forage decreased in acreage from 3,269,441 in 1899 to 3,088,105 in 1909, when the production was valued at $45,623,573, which was 27.4 per cent of the total value of all crops. Tobacco increased in acreage from 27,760 in 1899 to 41,742 in 1909, when the production was valued at $3,926,116. The value of the forest products of the farms was $7,986,599 in 1909, as compared with $6,481,181 in 1899.

Horticultural crops raised in Pennsylvania are fruits and nuts, small-fruits, potatoes and other vegetables and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $9,619,156, as compared with $8,707,131 in 1899. Small-fruits decreased in acreage from 12,271 in 1899 to 8,678 in 1909, when the production was 13,620,047 quarts, valued at $1,175,016. The total acreage of potatoes and other vegetables in 1909 was 357,430 acres and their value $22,092,197. Excluding potatoes, the acreage of the other vegetables increased from 79,126 in 1899 to 94,111 in 1909, when the production was valued at $10,013,920. The acreage devoted to the production of flowers and plants and nursery products increased from 4,274 in 1899 to 4,860 in 1909, when the production was valued at $4,725,987.

The production of all orchard-fruits in 1909 was 13,285,953 bushels, valued at $8,677,986. The production of apples, the most important of the orchard-fruits, was, in 1909, 11,048,430 bushels, valued at $5,557,616. The number of apple trees of bearing age in 1910 was 8,000,456; those not of bearing age, 2,501,185. The number of peach and nectarine trees of bearing age, in 1910 was 2,383,027; those not of bearing age, 2,179,386. The production in 1909 was 1,023,570 bushels, valued at $1,351,175. The other orchard-fruits produced were 378,825 bushels of pears, valued at $356,240; 295,158 bushels of plums and prunes, valued at $396,005; 475,093 bushels of cherries, valued at $909,975; 62,350 bushels of quinces, valued at $102,431; and 2,502 bushels of apricots, valued at $4,497.

The production of grapes in 1909 was 34,020,198 pounds, valued at $850,708. The grape-vines of bearing age in 1910 numbered 5,271,264; those not of bearing age, 8,252,811.

The total production of nuts in 1909 was 3,795,804 pounds, valued at $90,447. The individual production of the various nuts was: 2,162,471 pounds of black walnuts, valued at $39,306; 593,200 pounds of hickory-nuts, valued at $25,348; 233,834 pounds of chestnuts, valued at $15,185; 782,415 pounds of butternuts, valued at $9,408; 14,885 pounds of pecans, valued at $532; and 4,523 pounds of Persian or English walnuts, valued at $516.

Strawberries are the most important of the small-fruits grown in Pennsylvania, with raspberries and loganberries second in importance. The acreage of strawberries decreased from 5,667 in 1899 to 4,136 in 1909, when the production was 9,033,904 quarts, valued at $759,154. Raspberries and loganberries decreased in acreage from 3,938 in 1899 to 2,594 in 1909, when the production was 2,906,302 quarts, valued at $272,337. Blackberries and dewberries decreased in acreage from 1,383 in 1899 to 1,235 in 1909, when the production was 1,063,257 quarts, valued at $91,007. Other small-fruits produced were: 493,871 quarts of currants, valued at $42,181; 109,104 quarts of gooseberries, valued at $9,047; and 5,728 quarts of cranberries, valued at $503.

The acreage of potatoes in Pennsylvania increased from 227,867 in 1899 to 262,013 in 1909, when the production was 21,740,611 bushels, valued at $11,973,843. The more important of the other vegetables produced in 1909 were: 11,764 acres of sweet corn, valued at $507,736; 5,679 acres of cabbage, valued at $502,969; 4,204 acres of tomatoes, valued at $412,519; 1,096 acres of celery, valued at $254,693; 1,191 acres of asparagus, valued at $174,965; 551 acres of onions, valued at $107,307; and 1,752 acres of turnips, valued at $86,079. Vegetables the production of which was valued between $10,000 and $50,000 were green beans, beets, cantaloupes and muskmelons, carrots, cucumbers, horse-radish, lettuce, green peas, radishes, rhubarb, spinach, and watermelons. Vegetable products, the production of which was valued at less than $10,000, were cauliflower, pop-corn, eggplant, kale, parsley, parsnips, green peppers, pumpkins, rutabagas and squash.

Flowers and plants increased in acreage from 1,073 in 1899 to 2,032 in 1909. The area under glass in 1909 was 13,846,672 square feet, of which 12,887,672 were covered by greenhouses, and 959,000 by sashes and frames. The value of the flowers and plants produced in 1909 was $3,803,418, as compared with $2,246,075 in 1899.

The acreage devoted to nursery products decreased from 3,201 in 1899 to 2,828 in 1909, when the value of the nursery products produced was $922,569, as compared with $541,032 in 1899. The production of flower and vegetable seeds was valued at $36,316 in 1909, as compared with $104,229 in 1899.

John P. Stewart.

EAST NORTH CENTRAL STATES.

Ohio.

Ohio (Fig. 2496) is essentially an agricultural state. This is not because the soil and climate are not adapted to the production of horticultural products, but rather for the reason that in early days the markets for fruit and vegetables were limited. With the growth of cities and the opening of markets in other states and countries, there has been a steady increase in the production of most kinds of horticultural products which are adapted to the climate.

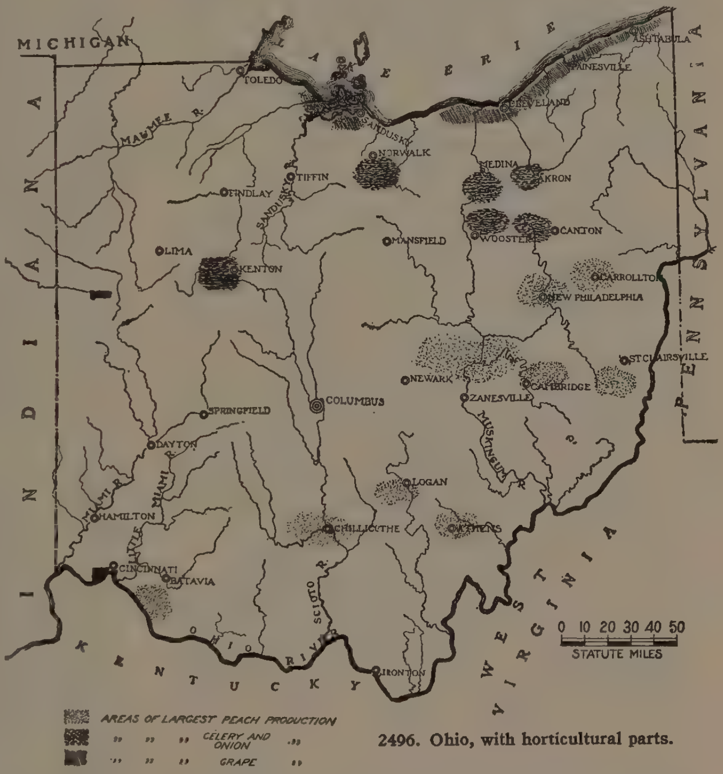
The climate is well suited to fruit-culture except in an occasional season. Even in such cases, losses by extreme cold may usually be avoided by proper selection of site. There are only limited areas where the soils are unadapted either to fruits or vegetables. There are many soils which are found to be well adapted to specialized crop-production. The annual rainfall is about 38 inches and crop failures because of severe drought seldom occur.

The influence of Lake Erie, on the north, is very marked upon fruit-culture in general. In that region, peach buds are seldom killed in winter, while both early and late frosts seldom harm early blossoms or late-ripening fruits. Fruit-production for this reason has been greatly stimulated in that region. Convenience to markets has been a potent factor also. The soil in the lake region varies from a sandy to heavy clay, thus making it possible to grow all of the fruits which thrive within the state. More back-to-the-land fruit-growers are found in this region than in any other part of the state. The larger number, however, are men of considerable practical experience, most of whom are successful along special lines of fruit-culture.

The hill lands in the southern and eastern parts of the state constitute another distinct division suitable for most kinds of fruits. The special virtue of these lands is that they give high color, good flavor and excellent keeping quality to apples, peaches and pears. This is particularly true of the greatest elevations. Comparative freedom from frost is another virtue of the hill lands. In many cases, however, the soil on the hills is much worn and lacking in humus. The success of the Experiment Station in the use of commercial fertilizer on apple orchards in this region has stimulated apple-growers to practise better methods. Many orchards have been brought back from low crop-production to a very satisfactory condition of fruitfulness. The restoration of humus has not kept pace with fertilizing, but without doubt this important feature of orchard rejuvenation will not be neglected much longer.

On the whole, Ohio compares favorably with other states as to horticultural possibilities, but not as to development. However, there have been marked increases in crop-production within recent years of apples, peaches, cherries, potatoes, onions, celery, tomatoes, greenhouse vegetables and canning crops. There has been some falling off in grapes and berries, but enough are still produced for the local markets.

Increased interest in horticultural work is manifest along many lines but the greatest is in apple-culture. Old orchards are decaying rapidly but many new ones have been planted and the best of the old ones rejuvenated. The apples have been greatly improved in quality by proper care of the trees. This is plainly shown by the rapidly improving excellence of the apple shows, both as to quality and quantity of fruit displayed. The stimulus of the shows seems to have been more to improve the quality than to increase the quantity, and yet many orchards have been planted recently. Many of these are of considerable size; 50- and 100-acre orchards are becoming quite common. It does not appear, however, that overplanting has been done as the standard of excellence is maintained. The greater part of the planting is in the eastern and southeastern part of the state. Nearly all of the orchards planted are for commercial purposes. Home orchards are decaying more rapidly than new ones are being planted.



2496. Ohio, with horticultural parts.

It cannot be said that there are any well-defined apple-belts within the state. Apple orcharding is usually carried on with general farming or with some other line of fruit-growing. Mature apple orchards are not usually cultivated in the hilly part of the state. Mulching is often practised where material can be secured. Young orchards are usually cultivated for a few years, but orchards set in grass and well mulched are not uncommon.

Rome Beauty is the general favorite for market in the southern part of the state and Baldwin takes the same place in the northern part, although it is not planted so exclusively as the Rome Beauty. Ben Davis has been a favorite in all sections but its popularity is waning, although it is still retained by many growers in the southern counties. There are no other varieties so extremely sectional as those named, although Rhode Island Greening and Northern Spy are nearly so in the north, and Willow Twig in the eastern part of the state.

Peaches are not grown to any extent commercially except along the southern shore of Lake Erie. Peach orchards have nearly supplanted vineyards in the lake counties. Partial or full crops are often produced in the central and southern part of the state, and these have the effect of keeping the industry alive, although less flourishing in Athens, Muskingum and Coshocton counties than formerly. Better cultural conditions and more care in protecting against peach-tree enemies are given peach orchards in the lake region than elsewhere in the state. Ottawa is the best peach county of the state in sureness of crop, care given and crop-production.

Pears are not extensively grown in any part of Ohio, the Kieffer being planted more than any other variety. This variety has recently shown such susceptibility to blight that it is now regarded as a menace to pear- and apple-culture. The destruction of Kieffer pear trees is regarded by some as a necessary step in orchard sanitation.

American and Japanese plums are discarded by plum-growers and but few remain to mark an erratic and unprofitable venture. No varieties but European are now planted, but the attention given to plum-culture within the state is limited.

The culture of cherries is confined almost wholly to sour varieties. The center of this industry is at Clyde, but small orchards are found in most parts of the state.

Grape-culture along the lake shore east of Cleveland has fallen off considerably in recent years because of the encroachment of the city and failure of the growers to control the berry moth. Prices also have been unsatisfactory. The manufacture of unfermented grape-juice, which has assumed considerable proportions, has helped to improve prices somewhat on the islands, but has not stimulated planting to any extent.

Small-fruits of all kinds are grown in sufficient quantities for the home markets, by local growers, but few shipments are made to points outside the state. There are no small-fruit belts within the state, although more are grown in the northern part than elsewhere.

There is much interest in Persian walnuts and pecans at present, and plans have been considered of starting orchards of these nut-bearing trees. Along Lake Erie and the Ohio River, a few trees are known to be producing fruit. Thus far both of these species appear to be tender in winter. Persian walnut trees, except along the lake shore, almost always die back to the ground in winter. Pecans are more hardy, and early ripening varieties may prove satisfactory. But little effort has been made, however, to use grafted trees, especially in the case of Persian walnuts, thus courting failure. No orchards are known to have been planted of these nut-trees, and the same is true of other nut-bearing trees.

Market-garden crops, including potatoes, bring greater returns than the fruit crops. Potato-culture has assumed considerable proportions in Portage, Stark, Summit, Cuyahoga and Wayne counties, following closely what is termed the "wheat belt." Hamilton produces more early potatoes than any other county.

Celery and onions are grown largely on mucklands in Hardin, Huron, Medina, Wayne, Cuyahoga, Stark and Ashtabula counties. It has been found possible to sub-irrigate some of these muck farms, making crop production more sure.

Tomatoes are grown in various parts of the state, in large quantities for canning factories. In the southeastern part of the state, near Marietta, several hundred acres are devoted to growing early tomatoes. Staking the plants is the universal practice, as it is conducive to early maturity.

Early cabbage is grown in the same locality and at various other points along the Ohio River. Late cabbage, for krout, is an important crop in Sandusky and Seneca counties.

Several thousand acres, in various parts of the state, are devoted to cucumbers for pickling establishments. Canneries use sweet corn, tomatoes and peas almost exclusively, except peaches in the peach-belt.

Vegetable-culture under glass has assumed very large proportions at Ashtabula, Cleveland, Columbus, Newark and Toledo, but vegetable houses of considerable size are found in all parts of the state. Grand Rapids lettuce, tomatoes and cucumbers are the principal crops grown.

There are about 300 acres under glass within the state devoted to vegetable-culture, with an investment of $6,000,000. One house in Toledo covering 10 acres, is said to be the largest in the world devoted to vegetable-culture. Vegetable-forcing about Cincinnati has been conducted mostly in hotbeds and coldframes, but greenhouses are now taking the place of beds. The greatest development of this industry is at Ashtabula, Toledo, Cleveland, Columbus, Newark, and Barberton. Small houses are also found in many towns. The usual custom is to change the soil in vegetable houses at frequent intervals. Soil-sterilization by steaming is practised, and manure or some fresh compost added each year. It has been found that mulching the soil with coarse manures as soon as the spring crops are off, and watering frequently, answers essentially the same purpose as sterilization. Beds have been kept in good condition eight years by this method.

Floral establishments are found in nearly every city and town. The larger number of these are for cut-flowers but a few do a mail order business and others grow pot and bedding plants.

The nursery business is very large and supplies more trees than are needed within the state, possibly apple trees excepted. A large increase in ornamental stock is reported, and there is evident improvement in methods of planting home grounds.

Among those influential in the early development of Ohio horticulture are: J. P. Kirtland (Volume III, page 1582); J. A. Warder (page 1602), with whom were closely associated Nicholas Longworth (page 1585), A. H. Ernst (page 1574), S. S. Jackson and A. H. Hoopes; George W. Campbell (page 1568); M. B. Bateham; F. R. Elliott (page 1574); Nelson Cox, who demonstrated the feasibility of apple-culture on the hill lands of the state; A. W. Livingston, who greatly improved the tomato and N. Ohmer.

Public-service agencies for horticulture.

The College of Agriculture of Ohio is located at Columbus. There are six teaching members of the horticultural staff.

The Experiment Station is at Wooster. Much experimental work is in progress at three branch stations, or test farms, belonging to the station, and six county farms under station control.

The Bureau of Nursery and Orchard Inspection at Columbus has charge of the inspection work.

The first horticultural organization was the Ohio Pomological Society in 1847. The name was afterward changed to the Ohio State Horticultural Society.

Statistics (Thirteenth Census).

The approximate land area of Ohio in 1910 was 26,073,600 acres. The land in farms was 92.5 per cent of the land area, or 24,105,708 acres. Of this land in farms, the improved farm land numbered 19,227,969 acres; the woodland 3,285,376 acres; and other unimproved land in farms 1,592,363 acres. The total number of farms in 1910 was 272,045, and the average acreage 88.6 acres. [The total area of the state is 41,040 square miles.]

The leading agricultural crops of Ohio are cereals, hay and forage, tobacco, and forest products of farms. The acreage devoted to cereals decreased from 8,214,960 in 1899 to 7,649,873 in 1909, when the production was valued at $137,907,934, which was 59.9 per cent of the total value of all crops of the state. The acreage of hay and forage was 3,015,261 in 1899 and 3,306,461 in 1909, when the production was valued at $42,357,364. Tobacco increased in acreage from 71,422 in 1899 to 106,477 in 1909, when the product was valued at $8,998,887. Forest products of farms in 1909 were valued at $5,761,941, as compared with $5,625,897 in 1899.

Horticultural crops produced in Ohio are fruits and nuts, small-fruits, potatoes and vegetables, and flowers, plants, and nursery products. In 1909 the value of the fruits and nuts produced was $6,561,861, as compared with $7,138,734 in 1899. Small-fruits decreased in acreage from 21,121 in 1899 to 11,591 in 1909, when the production was 15,721,023 quarts, valued at $1,296,343. In 1909 the total acreage of potatoes and other vegetables was 337,412, and their value $20,875,927. Excluding potatoes, the acreage of the other vegetables increased from 103,346 in 1899 to 123,461 in 1909, when the production was valued at $11,393,791. The raising of flowers and plants and nursery products is of considerable importance, the acreage having increased from 5,384 in 1899 to 5,788 in 1909, when the production was valued at $3,245,181.

The total production of orchard-fruits produced in 1909 was 6,711,208 bushels, valued at $5,691,530. Apples contributed about two-thirds of this quantity, and peaches and nectarines most of the remainder. The number of apple trees of bearing age in 1910 was 8,504,886; those not of bearing age 2,438,436. The production in 1909 was 4,663,752 bushels, valued at $2,970,851. The number of peach and nectarine trees of bearing age in 1910 was 3,133,368; those not of bearing age, 2,092,300. The production in 1909 was 1,036,340 bushels, valued at $1,349,311. The production of other orchard-fruits was: pears, 374,871 bushels, valued at $332,727; cherries, 338,644 bushels, valued at $657,406, 215,657 bushels of plums and prunes, valued at $278,505; 81,101 bushels of quinces, valued at $101,369; and 835 bushels of apricots, valued at $1,343.

The production of grapes in 1909 was 43,933,207 pounds, valued at $858,594. The vines of bearing age in 1910 numbered 8,326,800; not of bearing age, 455,750.

The production of nuts in 1909 was 559,093 pounds, valued at $11,691. This production consisted of 354,135 pounds of black walnuts, valued at $4,645; 135,626 pounds of hickory-nuts, valued at $3,856; 36,091 pounds of chestnuts, valued at $2,584; 29,100 pounds of butternuts, valued at $360; 2,461 pounds of Persian or English walnuts, valued at $154; and 1,010 pounds of pecans, valued at $70.

Strawberries are by far the most important of the small-fruits, with raspberries and loganberries, and blackberries and dewberries second and third respectively. The acreage of strawberries decreased from 9,373 in 1899 to 4,706 in 1909, when the production was 8,501,065 quarts, valued at $677,767. Raspberries and loganberries decreased in acreage from 6,795 in 1899 to 3,869 in 1909, when the production was 4,029,480 quarts, valued at $364,272. The acreage of blackberries and dewberries decreased from 3,397 in 1899 to 2425 in 1909, when the production was 2,465,407 quarts, valued at $195,294. Other small-fruits produced in 1909 were: 460,575 quarts of currants, valued at $39,829; 255,840 quarts of gooseberries, valued at $18,404; and 4,256 quarts of cranberries, valued at $352.

The acreage devoted to the production of potatoes in Ohio increased from 167,590 in 1899 to 212,808 in 1909, when the production was 20,322,984 bushels, valued at $9,377,955. Of the other vegetables, the more important in 1909 were 6,132 acres of onions, valued at $858,440; 17,298 acres of sweet corn, valued at $528,162; 8,263 acres of tomatoes, valued at $501,020; 6,279 acres of cabbage, valued at $366,901; 1,473 acres of celery, valued at $331,230; and 1,665 acres of cantaloupes and muskmelons, valued at $154,434. The value of other vegetables produced was as follows: asparagus, $39,391; green beans, $39,352; pop-corn, $16,878; cucumbers, $113,238; lettuce, $76,372; green peas, $69,009; radishes, $15,194; rhubarb, $11,329; turnips, $31,791; and watermelons, $46,063. Vegetables produced, valued at less than $10,000, were beets, carrots, cauliflower, horse-radish, parsnips, green peppers, pumpkins, spinach, and squash.

The acreage devoted to the production of flowers and plants increased from 685 in 1899 to 1,070 in 1909. The area under glass in 1909 was 7,582,562 square feet, of which 7,091,976 were covered by greenhouses, and 490,586 by sashes and frames. The value of the flowers and plants produced in 1909 was $2,384,830.

There was a slight increase in the acreage devoted to nursery products—from 4,699 in 1899 to 4,718 in 1909, when they were valued at $860,351, as compared with $538,012 in 1899.

W. J. Green.

Indiana.

Indiana (Fig. 2497), classed among the North Central States, has a land area of 23,068,800 acres. The greater part of the state is gently undulating, yet much of the highest land in the central counties is very level. The mean elevation of the state is estimated at 700 feet above sea-level. The highest lands are above 1,000 feet and are found along the Ohio line in east-central Indiana and near the Michigan line in extreme northeastern Indiana. The area in which the altitude is from 500 to 1,000 feet constitutes four-fifths of the entire state. The lowest elevation within the state is found in the western and southwestern counties along the Wabash River, where the land surface rises in general to an altitude of less than 500 feet above sea-level.

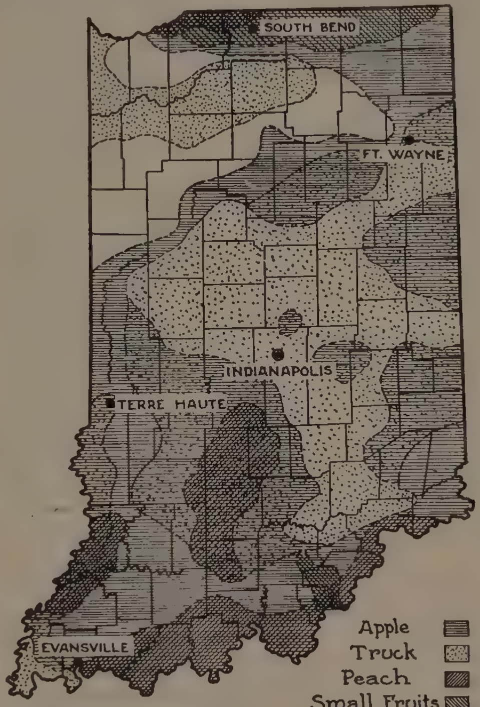
The climate differs little from the northern or middle states of the Atlantic seaboard. The mean annual temperature for the state is 52.3°, and the average rainfall is 38.4 inches.

Indiana has never been looked upon as a fruit-growing state. This is due to a happy combination of circumstances and conditions which make Indiana preëminently an agricultural state. Corn has been "king" in Indiana and probably always will be. The soil and climate of the middle western states are especially adapted to the necessary food-crops. These crops have been produced in an abundance and have overshadowed the horticultural crops.

From the earliest years of the last century, when Johnny Appleseed made his plantings in the wilderness, it has been evident that the soil and climate of the state were adapted to fruit. Numerous of these early orchards can be identified at present and their fruits are often shown at the state apple shows. Henry Ward Beecher, writing from Indianapolis in 1843, says that at that time there were "eighteen nurseries in the state whose proprietors are chiefly supported by their sales. Apple trees sell for 10 and pear for 20 cents. An orchard is to be found upon almost every farm and lately the pear has been made more than ever sought after. . . . Long summers, brilliantly clear atmosphere, great warmth and dryness during the fall ripening months, give our fruit great size, color and flavor."

The early horticulture was principally along the Ohio River and its smaller tributaries. Large plantings were made to apples and peaches. With the experiences of the Dufours ever before them, the early horticulturists paid very little attention to the grape. Nevertheless, several vineyards were planted on the terraced river bluffs only to fall easy victims to plant disease and insect pest. Some of the largest peach and plum orchards of the country were then to be found in Jefferson, Floyd, Clark, Harrison and Perry counties, in the southern part of the state. In fact, fruit-growing was the principal industry of the section.

At length there came a change in condition. The pear and apple orchards suffered from the fire blight. The peach orchards were ravaged by the San José scale and the yellows. The codlin-moth and the curculio multiplied unchecked; the scab, the various rots and other fungous diseases reduced the crops in both quantity and quality and many of the once profitable orchards were practically abandoned except for an occasional year of excessive production. The fruit was then perhaps harvested, but, owing to its poor quality, found a slow sale on a heavily supplied market.



2497. Indiana, to show horticultural regions.

With the establishment of the experiment station in 1887 dates the present revival in horticulture. Control measures were developed for crop pests and disease. Large companies have been formed for speculation in fruit lands, for exploitation of orchard-renovation schemes or for straightforward business development of commercial fruit-growing.

Time has shown that the soil and climate of Indiana are adapted to all of the horticultural crops of its latitude. This certainty of production, coupled with the location of the state make it a very attractive district for the production of perishable horticultural crops. Indianapolis, the capital and center of the state, is within 50 miles of the center of population of the United States. It is the geographical center of the territory stretching from Maine to Colorado, which embraces 92½ per cent of the total population of the nation. A circle with a 300-mile radius, having Indianapolis as its center, includes over one-quarter of the population of the country.

Another factor of no little importance to the horticultural interests of the state is the low price of lands suited to the various horticultural crops. Excellent land for orchard and truck crops can be purchased from $25 to $50 an acre.

Many horticultural crops are now grown in Indiana, but the apple easily stands first. The state ranks seventh in the ten-year average production of this fruit, so far as quantity is concerned. The present apple-growing sections are found in the northern counties, the valleys of the Wabash, White-water, White and Ohio rivers and the south-central hill counties. Large commercial plantings are being made in these regions. In the northern sections, the Baldwin, Spy, and Greenings predominate. In the central and southern sections the new plantings are being made of Grimes, Rome, Winesap, Stayman, and Ben Davis. The early sorts are not being planted so extensively as the market seems to warrant. Several large plantations, however, have used Yellow Transparent, Wealthy, Duchess, and Wagener as fillers. The larger part of commercial orchards are well sprayed. The very abundance of pests makes this a necessity. Unsprayed trees in Indiana live in the shadow of a signed death warrant. The San José scale, blotch, bitter-rot and blight soon remove the unfit. These pests are the best friends of the commercial grower for they clear his markets of undesirable bulk stock. Lime-sulfur is generally used as a winter spray for San José scale and general sanaticide. Bordeaux has been replaced in the northern sections by dilute lime-sulfur. In the central and southern regions, however, where blotch and bitter-rot are ever present, the old tried and true bordeaux is still used. Dry arsenate is almost universally accepted as the standard insecticide for chewing insects. The bulk of the Indiana apple crop is marketed in the barrel. The box is receiving attention in some sections but is not yet a common package. The fancy and choice grades are generally stored in commercial cold-storage rooms. The state is well equipped with storage facilities. Excellent houses are found in Indianapolis, Vincennes, Washington, Seymour, Martinsville, Terre Haute, Brazil, South Bend and Ft. Wayne.

The Indiana orchardist is now making the most of his long neglected opportunities. Old orchards are being leased and new ones planted on every side. Neglected orchards are being pruned, cultivated, sprayed, and fertilized as never before.

Indiana has given one hundred varieties of apples to the pomology of the country. The most important of these are: Banana, Clayton, Indian, Indiana Favorite, Pound Sweet, Ragan, Ronk, and Wilson. Other Indiana varieties are the Hoosier Cling peach, Wilder currant, Gregg raspberry, and the Taylor and Snyder blackberries.

The peach, plum, and cherry thrive in every part of the state and are always found in the home orchard. They are of commercial importance, however, only in exceptionally favored locations, along the southern shore of Lake Michigan, the lower Wabash Valley, the central hill counties, and the old Ohio Valley peach region. Orchards in these locations do remarkably well and the industry is being extended each year. Commercial peach plantings are largely limited to the Elberta. This variety does exceedingly well in the southern sections. Cherry orchards are planted only of Early Richmond and Montmorency. Plums are planted very little in a commercial way.

Small-fruit plantations are found around every city of importance. Sections of Floyd and Clark counties (southeastern part of Indiana) are devoted almost entirely to the production of early berries for northern markets. The fruit from this region strikes a free market and finds a very ready sale. The northern tier of counties also produce berries of high quality and at a time of free and brisk markets.

Several wild fruits and nuts grow to perfection in Indiana and have assumed commercial importance in some localities. The cranberry and blueberry are found in the muck, swampy soil regions, the persimmon and pawpaw in all parts of the state and the pecan in the southern river-bottoms.

The trucking interests are especially strong in Indiana. Thousands of acres along the Kankakee River are of a muck formation. When properly drained, this soil is excellent for the large number of vegetable crops

Onions are the most important crop grown in this region. The land is drained by county ditches and intricate systems of tile drains. Large areas are generally held by one owner who leases the land to foreign labor. The Southport Globes, yellow and red, are almost exclusively grown. Yields of 800 to 900 bushels to the acre on this rich soil are not at all uncommon. Celery is also a favorite crop for this soil. Golden Self-blanching, Winter Queen, and Giant Pascal are grown for the Chicago market. Large areas of cabbage are planted mainly for the kraut factories. The varieties most generally grown are Flat Dutch, All Seasons, and similar sorts. Potatoes are grown for the early and late markets. The main planting is of the late varieties, generally Rural New Yorker. Large fields of peppermint are grown for the oil-stills. Excellent yields are secured and handsome profits made.

The central area or corn-belt is a large producer of the canning crops. Tomatoes and corn are the principal crops. The sandy soils of Knox (in the southwestern part of the state) and surrounding counties produce cantaloupes and watermelons which supply the markets of the country by train-loads. Sugar-beets are grown in several sections of the state but reach their highest state of excellence in Adams, Well, and Jay counties, in the eastern part of the state. The truck industry of Indiana is of great importance and is very diversified.

No sketch of the early history of Indiana horticulture, however fragmentary and incomplete, can omit the names of some of the pioneer horticulturists of the state. The names of the Ragans, of Teas, and Fletcher, and Warder, and a dozen of their fellows, will always be remembered in connection with the early founding, the rapid spread, and the abundant success of pioneer Indiana horticulture.

The nursery business in Indiana has kept pace with the ever-growing demand for horticultural stock. There are now 150 regularly inspected nurseries in the state. The largest cherry nursery in the country is located at Vincennes. Several nurseries catering only to the ornamental trade are found near Indianapolis. The larger number of firms, however, deal in general stock and cater especially to the general farm orchard.

Indiana floriculture is well developed and in a thriving condition. Large ranges of commercial houses are found around the more important cities, such as Ft Wayne, South Bend, Indianapolis, Terre Haute, and Evansville. These ranges are devoted primarily to the wholesale and retail trade. The plant-breeder and introducer seems to favor the smaller towns. Some of the most important varieties of roses, carnations, and chrysanthemums have been produced in small Indiana plants. The Newcastle roses are justly famous the world over. The Sunburst and Ophelia roses, as well as many others, were produced at Richmond. One of the largest breeders and introducers of carnations in the United States is located at LaFayette.

Public-service agencies for horticulture.

Early in 1865, the State Legislature obligated the state to "accept and claim the benefits of the provisions of the Acts of Congress, approved July 2, 1862, and April 4, 1864," which provided for the land-grant colleges. The state further accepted donations from John Purdue and other citizens of Tippecanoe County, and in 1869 the Legislature located the University at Lafayette. This same act provided that the institution be called "Purdue University." While named after a private individual, the University is, however, a land-grant college and is exclusively under state control. The work of this institution is divided into three district divisions: The Collegiate Departments; Agricultural Experiment Station; and Agricultural Extension Department. There are thirteen members of the horticultural staff. Forty-two bulletins have been issued from the horticultural department.

Several of the secondary colleges of the state are offering either special work in horticulture or courses in applied botany. The most complete course of this kind is that offered by Winona Agricultural College. Under a legislative act of 1911, the teaching of agriculture became compulsory in the rural schools. Special courses in fruit-growing and vegetable-gardening have been outlined and published for the seventh and eighth grades and for high-schools. This rural school work is closely supervised either by the special county agricultural agents or special agricultural supervisors.

The state maintains a special department for the enforcement of horticultural laws. This division is headed by the State Entomologist. His main duty is that of guarding against the introduction and spread of noxious insects and plant diseases.

The Horticultural Society is one of the most important public-service agencies for horticulture in Indiana. It was founded in 1860.

Statistics (Thirteenth Census).

The approximate land area of Indiana, according to the Census Report of 1910, is 23,068,800 acres. The land in farms is 92.3 per cent of the land area, or 21,299,823 acres. The number of acres of improved land in farms is 16,931,252; that of woodland 3,370,791, and other unimproved land in farms numbers 997,780 acres. The number of all the farms in the state, in 1910, was 215,485. The average acreage to a farm was 98.8. [The total area is 36,354 square miles.]

The leading agricultural crops of the state are cereals and hay and forage. In 1909, the cereals contributed about three-fourths, or 74.4 per cent of the total value of all crops, and hay and forage about one-eighth, or 12.2 per cent. Of the improved land in the state in 1909, 51.7 per cent, or 8,752,732 acres were occupied by cereals, the products of which amounted to $151,898,146. The acreage of hay and forage in 1909 was 2,300,579, and the value of the products, $24,883,461. The acreage devoted to tobacco in Indiana increased from 8,219, in 1899, to 23,694 in 1909, when the value of the products was $2,145,193. The value of the forest products of the farms of Indiana, in 1909, was $5,603,322, about the same as in 1899, when it was $5,235,459.

Horticultural crops grown are fruits and nuts; small-fruits; vegetables, including potatoes, sweet potatoes and yams; and flowers and plants and nursery products. The total value of fruits and nuts grown in 1909 was $4,004,367, as compared with $3,522,896, their value in 1899. The acreage devoted to raising small-fruits decreased from 13,115 acres, in 1899, to 5,919 acres in 1909, when 7,424,831 quarts of fruit were produced, valued at $612,725. In 1909, the total acreage of potatoes and other vegetables was 215,332, and their value, $11,454,036. Excluding potatoes, and sweet potatoes and yams, the acreage of the other vegetables was 114,267, and their value, $7,498,024, as compared with an acreage of 95,434 in 1899, when the value of their products was $4,524,435. The acreage devoted to the growing of flowers and plants and nursery products increased from 1,820 acres, in 1899, to 2,346 in 1909, when the products were valued at $1,624,278.

The total quantity of orchard-fruits produced in 1909 was 4,713,537 bushels, valued at $3,709,275. Apples contributed more than half of this quantity, with peaches and nectarines next in importance. The production of apples alone, in 1909, was 2,759,134 bushels, valued at $1,720,811; that of peaches and nectarines, 1,174,389 bushels, valued at $1,123,248; that of cherries, 363,993 bushels, valued at $508,516; and that of pears, 319,925 bushels, valued at $243,698. Plums and prunes were produced to the value of $89,073; quinces, to the value of $22,431; apricots, to the value of $1,472; and mulberries, to the value of $26.

The grape-vines of bearing age in 1910 were 1,049,232, and those not of bearing age, 149,441. The production in 1909 was 12,817,353 pounds, valued at $287,707.

The total production of nuts in 1909 was 439,644 pounds, valued at $7,344. Black walnuts are by far the most important of the nuts grown in Indiana. In 1909 the production of black walnuts was 378,842 pounds, valued at $4,386; that of pecans, 19,287 pounds, valued at $1,940; and that of hickory-nuts, 31,950 pounds, valued at $753.

The total acreage of small-fruits in 1909 was 5,919, and in 1899, 13,115, a decrease of 54.9 per cent. The production in 1909 was 7,424,831 quarts, as compared with 22,088,000 quarts in 1899, and the value, $612,725, as compared with $1,113,527. Strawberries are by far the most important of the small-fruits, with raspberries and loganberries, and blackberries and dewberries ranking second and third respectively. The acreage of strawberries decreased from 4,714, in 1899, to 2,574 in 1909, when the production was 3,759,132 quarts, valued at $310,430. The acreage of raspberries and loganberries decreased from 3,277, in 1899, to 1,412 in 1909, when the production was 1,595,921 quarts, valued at $140,204; and the acreage of blackberries and dewberries decreased from 3,192, in 1899, to 1,347 in 1909, when the production was 1,482,909 quarts, valued at $113,322. Other small-fruits produced in 1909 were 320,963 quarts of gooseberries, valued at $25,682; 208,049 quarts of currants, valued at $16,901; and 7,552 quarts of cranberries, valued at $498.

Of the vegetables grown in Indiana, the potato is by far the most important. In 1909, the acreage devoted to the potato was 99,504, and the production was 8,905,679 bushels, valued at $3,816,126. The leading vegetables grown in 1909, their acreage and value of products were: tomatoes, 18,472 acres, value of product, $501,180; onions, 4,048 acres, valued at $488,811; watermelons, 7,915 acres, valued at $291,027; cantaloupes and muskmelons, 3,855 acres, valued at $198,531; sweet corn, 7,977 acres, valued at $188,054; sweet potatoes and yams, 1,561 acres, valued at $139,886; cabbage, 2,107 acres, valued at $126,052; cucumbers, 2,095 acres, valued at $111,268; and green peas, 4,084 acres, valued at $103,613. Vegetables of less importance grown were asparagus, beans, celery, pop-corn, lettuce, radishes, rhubarb, and turnips.

The growing of flowers and plants is of some importance in Indiana, the acreage increasing from 174 acres, in 1899, to 496 acres in 1909, an increase of 185.1 per cent. The area of land under glass, in 1909, was 3,741,269 square feet, of which 3,650,443 square feet were covered by greenhouses and 90,826 square feet by sashes and frames. The value of the flowers and plants, in 1909, was $1,212,891, as compared with $400,730, in 1899, an increase of 202.7 per cent.

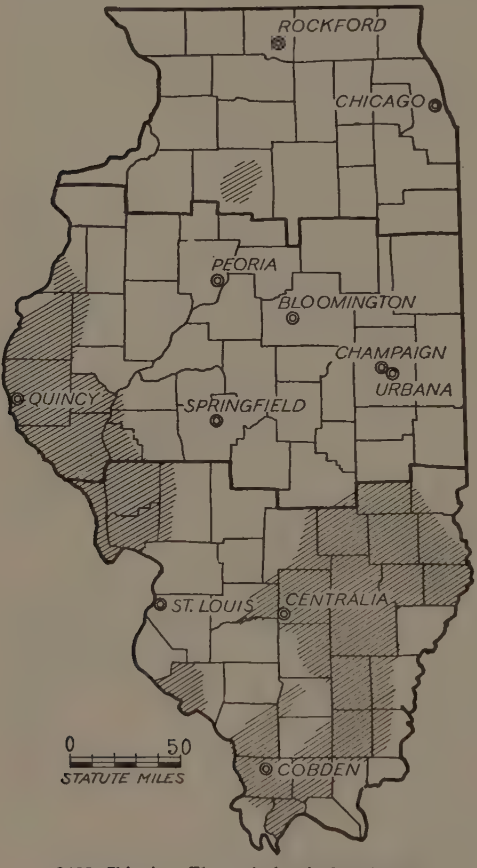
The acreage devoted to the growing of nursery products increased from 1,646 acres, in 1899, to 1,850 acres in 1909, an increase of 12.4 per cent. The value of the nursery products sold in 1909 was $411,387, as

compared with $254,893 in 1899, an increase of 61.4 per cent.
M. W. Richards.

Illinois.

The state of Illinois (Fig. 2498) lies in the heart of the Mississippi Valley, the most fertile portion of the United States. Its eastern boundary is over 700 miles from the Atlantic coast; it has a range north and south of a little over 350 miles, extending from 37° to 42° 30′ north latitude, and a breadth east and west of about 200 miles at its widest point. In spite of its great length, the difference in mean annual temperature between the extreme northern and southern parts of the state is only 10° F.

Soil conditions alone considered, Illinois stands, agriculturally, at the very forefront. It is known as the great prairie state, and with the exception of Delaware and Louisiana, is the most level state in the Union. Third in population (1910), and second in railroad mileage, it is first in total value of agricultural products. Over nine-tenths of its total area is in farms. There are no considerable tracts of worthless land, and the statistics of the United States Census for 1910 show every one of the 102 counties to be fruit-producing.



2498. Illinois.—The main horticultural areas.

The most distinctive fruit section of Illinois is the southern third. This area contains something over 150,000 acres devoted to the growing of apples alone. Other deciduous fruits, notably peaches and pears, and small-fruits, especially strawberries, are also grown in large quantities in this part of Illinois. Increased shipping facilities and the coming into bearing of orchards already some time planted have brought southern Illinois into close competition with Michigan in the production of peaches.

The southern fruit district, as indicated on the map, lies between 37° and 39° 30′ north latitude, the former being the latitude of Norfolk, Virginia, and the latter that of Baltimore, Maryland. The climate of this district is best indicated by the fact that the isotherm 55° F. passes through the northern part of the district, the same temperature line also passing through the peach and sweet potato districts of Delaware and southern New Jersey. The 50° isotherm passes through Illinois about on the dividing line between the northern and central fruit districts, thus showing the mean annual temperature of the northern district to be practically the same as that of the great grape and small-fruit sections of central New York. It should also be noted that the mean annual temperature of the famous Santa Clara Valley and the Santa Cruz mountain wine-grape district is 55° F., or about that of Madison and Bond counties in Illinois.

In 1913 the total annual precipitation at Galena, in the extreme northwest corner of the state, was 32 inches; in Henderson County and from thence along a line northeast across the state and down to Ford and Iroquois counties, 34 inches; in a circle taking in Pike, Adams, Hancock, Fulton, Knox, and up to LaSalle and a little beyond into Kane and DeKalb counties, down to McClean and the northern parts of Champaign and Vermilion counties, then west across the state including DeWitt, Sangamon, and Morgan counties, 34 to 36 inches; directly south, in a section including Clark, Edgar, and the southern part of Vermilion County on the east, and Scott and Calhoun counties on the west, 36 to 38 inches; along a line entering the state in Madison County, bending north to the southern boundary of Macon County and thence southeast to Crawford County, 38 to 40 inches; from thence to the seven or eight extreme southern counties, which have an average precipitation of 46 to 48 inches and over, 40 to 44 inches. The mean annual rainfall for ten years up to and including 1913 at the Illinois Agricultural Experiment Station at Urbana, Champaign County, was 35.37 inches.

In recent years there has been a steadily increasing interest in the apple as a commercial crop. Taking the state as a whole, this fruit is far in advance of other tree-fruits in area planted, in size of individual orchards, and in crop values. The introduction of modern business methods which have in great part supplanted the careless and unprofitable methods common a decade or so ago has brought great changes, and has established commercial apple-culture upon a stable and profitable basis. Attention to cultural methods and details of management is now almost universal; grades of fruit are rapidly being standardized, storage facilities are utilized, and markets carefully studied. Many orchards that were formerly neglected have been renovated and made profitable, and the planting of new apple orchards as commercial ventures is increasing. These new projects evidence study and the effort to apply those fundamental principles that make for success. The varieties planted are few in number, chosen because of their known adaptability to the particular region and their established position in the market to be served. In planting, the varieties are distributed in such manner as to promote interpollination. For the northern and central districts, fall and winter varieties are most in favor for commercial planting, while in the southern district new orchards are largely of summer varieties. In large orchards, cultural operations are now performed by traction engines with such satisfactory results that the use of these tractors promises to become universal in all commercial orchards.

In the southern district of the state there is in progress a notable revival in peach-planting. This fruit was neglected for several years because of losses resulting from brown-rot, peach-scab, peach leaf-curl, and other diseases. With the demonstration that these diseases could be completely controlled by persistent application of perfected methods of spraying, return to planting began and has extended until the area in new peach orchards equals, if it does not exceed, the area newly planted with apples. Elberta is the variety most in favor for commercial planting.

According to the Census Reports for 1910, Illinois ranks third among the states in value of flowers and ornamental plants produced, and second in value of flower and vegetable seeds. The largest commercial establishment in the United States for the production of cut-flowers is that of Pullman Brothers of Morton Grove (having a total of 45 acres under glass). Chicago has been for years the second largest market in the United States for cut-flowers. The business has grown considerably of late, although exact figures are not obtainable. An interesting fact in this connection is that the Chicago market is supplied almost entirely by Illinois establishments, while the demand in New York City, which is the center of the greatest market for cut-flowers in the country, is met largely by floricultural interests located in New Jersey.

The nursery business is flourishing in Illinois. There are approximately 214 nursery establishments in Illinois which are regulated according to the inspection laws, ninety in the northern division, seventy-four in the central, and fifty in the southern.

Other branches of horticultural industry are also well developed. Gardening for the Chicago market forms a large and important business in itself, while the growing of vegetables for shipment in certain sections of southern Illinois has assumed large proportions. At times, from Cobden, in Union county, thirty cars of tomatoes are shipped in one day, and it is not unusual for sixty to seventy cars of produce to be shipped from that county in one day.

Market-gardening has also been well developed in the vicinity of nearly every city of any considerable size in the state. In a number of the gardens, modern methods of overhead irrigation are employed to supplement the natural rainfall in certain seasons. At many places the culture of vegetables under glass has become an important industry, the principal crops being lettuce and cucumbers. Among the counties of the United States, Cook County, Illinois, ranks first in acreage of cucumbers, third in acreage of cabbage, third in acreage of onions, fourth in acreage of lettuce, fourth in acreage of celery, and fourth in the production of radishes. Union County has a larger acreage of rhubarb than any other county in the United States, while Iroquois County ranks third in acreage of sweet corn. Illinois ranks second among the states in the production of sweet corn, and third in the production of squashes.

Watermelons constitute an important truck-crop in certain localities, the leading centers of the industry being Carmi, in White County, Beardstown, in Cass County, and Thomson, in Carroll County. The normal production in each of these regions is about 400 carloads a year.

Onions, and especially onion sets, are extensively grown in the vicinity of Chicago. Many of the sets are grown in small areas under contract by market-gardeners for seedsmen and other large dealers. However, there are a few growers who make a specialty of sets, and plant a large acreage every year. One firm operating within the city limits of Chicago, ordinarily produces over 200 acres of sets. In the weeding and harvesting seasons, a special train is run to bring their workmen from the city.

The most notable examples of landscape horticulture or landscape gardening in the state are to be found in the Chicago city park system, which is the largest and in some respects the finest in the entire country. A recent development is the promotion of an "Illinois way of planting," which tends to emphasize the prairie style of landscape gardening as opposed to the formal or gardenesque style, and to unify and give character to the state as a whole.

Most of the men and women who have been influential in promoting the horticultural interests of the state have been identified with the State Horticultural Society. Some of those who are no longer living who will be remembered for their connection with the advancement of the horticultural activities of the state are: H. Augustine, Normal; W. W. Barnard, Johnson; S. N. Black, Clayton; Arthur Bryant, Princeton (page 1567); A. C. Canfield, Springfield; H. L. Daw, Jacksonville; C. N. Dennis, Hamilton; Robert Douglas, Waukegan (page 1572); M. L. Dunlap, Savoy; Samuel Edwards, LaMoille; Geo. Endicott, Villa Ridge; Willard C. Flagg, Moro; O. B. Galusha, Peoria; R. O. Graham, Bloomington; W. H. Gullett, Lincoln; A. C. Hammond, Warsaw; Jas. Hartzorne, Joliet; P. J. Hauswirth, Chicago; Jos. Heinl, Jacksonville; E. S. Hull, Alton; John F. Jolly, Olney; W. B. Lloyd, Kinmundy; W. H. Mann, Gilman; S. G. Minkler, Oswego; J. M. Pearson, Godfrey; Jonathan Perriam, Chicago; G. H. Perrine, Centralia; F. K. Phoenix, Bloomington; Edgar Sanders, Chicago; J. B. Turner, Jacksonville; F. D. Voris, Neoga; and A. Washburn, Bloomington.

Public-service agencies for horticulture.

The land-grant college was established in Urbana, Champaign county, February 28, 1867. The institution was called the "Illinois Industrial University" until 1885, when the name was changed to the "University of Illinois." At first there was no special instruction or equipment in horticulture.

In 1888, the Illinois Agricultural Experiment Station was established at the University of Illinois; the Board of Trustees of the University assumed charge, and some of the farm land belonging to the University was set aside for experimental purposes. At that time there were two members of the horticultural station staff; there are now twenty-two. Experimental work is being carried on in pomology, olericulture, plant-breeding, and floriculture. The area set apart for horticultural interests is 360 acres, about 300 acres of which are devoted to instructional work and about 60 acres to experimental work. This will fluctuate, however, from time to time. Thirty-eight horticultural bulletins have been published by the station to date, and thirty-two circulars.

With the exception of courses in colleges teaching agriculture, no advanced or special instruction in horticulture is given in the state. However, most of the common and secondary schools of the state offer courses in agriculture, in connection with which elementary horticultural instruction is included.

As a result of a state-wide demand for advice upon the improvement of home and public grounds, the Department of Horticulture at the State University has organized a corps of men especially for extension work in landscape gardening. Four members of the staff devote their entire time to this phase of the work. It consists of making special designs for school and other public grounds to serve as illustrations of proper landscape planting in the respective communities, publishing circulars and pamphlets designed to stimulate an interest in rural and civic improvement, giving illustrated lectures at meetings of civic clubs, farmers' institutes, and other organizations, and of demonstration work in the planting of public and private grounds.

Inspection service for insects and plant diseases is provided for by an act of the legislature, now in force as amended July 1, 1909. All nursery stock shipped or delivered must bear a copy of certificate of inspection.

No laws in regard to fruit-grading are now in force in Illinois except those which have been enacted by the federal goverment. A standard of grading of apples which is universally followed in the state, however, is that adopted in 1903 by the Illinois State Horticultural Society. According to this standard, apples are graded as No. 1's, No. 2's, and culls.

The horticultural interests of Illinois have been well looked after and carefully placed on a permanent basis by the legislature. In 1874 an act was passed by that body establishing the Illinois State Horticultural Society (which was organized in 1855) as a public corporation of the state. The State Horticultural Society is divided into three subdivisions, the Northern, Central, and Southern Horticultural Societies, each taking in about one-third of the state (see map). For the advancement of floriculture, the Illinois State Florists' Association was incorporated under the laws of the state of Illinois, March 9, 1905.

Statistics (*Thirteenth Census*).

The approximate land area of Illinois, according to the Census Report of 1910, is 35,867,520 acres. Of this, 90.7 per cent or 32,522,937 acres are in farms; 28,048,323 acres of the farm land are improved; 3,147,879 acres are in woodland; and there are 1,326,735 acres of other unimproved land in farms. The number of farms in the state totals 251,872. The average acreage to the farm is 129.1 acres. [The total area of the state is 56,665 square miles.]

The leading agricultural crops are cereals and hay and forage. In 1909, 59 per cent of the improved land was occupied by the cereals, or 16,536,457 acres. The value of the products from the cereals was $297,523,098, which was 79.9 per cent of the total value of all the crops. Hay and forage occupied 11.9 per cent of the improved land, or 3,349,435 acres. The value of the products was $40,560,220, which was 10.9 per cent of the total value of all crops. Crops of lesser importance were broom-corn, which occupied 38,452 acres in 1909, the products of which were valued at $1,457,172; and the sugar crops, which occupied 16,220 acres, whose products were valued at $573,846. The value of the forest products of the farms was $3,325,259 in 1909 and $2,555,890 in 1899.

Horticultural crops grown are fruits and nuts, vegetables including potatoes, small-fruits, and flowers and plants and nursery products. The value of fruits and nuts grown in 1909 was $4,304,847, as compared with $4,168,500 in 1899. The total acreage of potatoes and other vegetables in 1909 was 268,911, and their value $16,300,654, which is far above the value of any of the other horticultural crops. The acreage of small-fruits was 11,723 in 1909, as compared with 16,794 in 1899, a decrease of 30.2 per cent. The value of the small-fruits in 1909 was $1,109,747. The raising of flowers and plants and nursery products is of comparative importance, 4,793 acres being devoted to them in 1909 and the product being valued at $4,517,085.

The total quantity of orchard-fruits produced in 1909 was 4,939,211 bushels, valued at $3,857,743. Apples produced three-fifths of this quantity, the production in 1909 being 3,093,321 bushels, valued at $2,111,866. Peaches and nectarines were next in importance of the orchard-fruits, the production being 1,222,570 bushels, valued at $999,516. In 1909 the production of cherries was 287,376 bushels, valued at $453,474; that of pears, 249,365 bushels, valued at $202,965; that of plums and prunes, 78,566 bushels, valued at $80,384; that of quinces, 6,723 bushels, valued at $8,037; and that of apricots, 1,250 bushels, valued at $1,457.

Grapes produced in 1909 amounted to 16,582,785 pounds, valued at $426,468. The production in 1899 was 20,009,400 pounds.

The total production of all the nuts in 1909 was 714,478 pounds, valued at $20,550. The most important of the nuts were the pecans, producing 107,069 pounds, valued at $10,301; the black walnuts, producing 530,730 pounds, valued at $7,411; and hickory-nuts, producing 60,124 pounds, valued at $1,954. The nuts of lesser importance were the Persian or English walnuts, the chestnuts, and the butternuts.

Of the small-fruits, strawberries are the most important, with blackberries and dewberries, and raspberries and loganberries ranking second and third, respectively. The acreage of strawberries in Illinois in 1909 was 5,410, producing 8,031,824 quarts of berries, valued at $613,917; the acreage of blackberries and dewberries was 3,503, producing 2,915,473 quarts of berries, valued at $237,058; and the acreage of raspberries and loganberries was 1,945, producing 1,834,337 quarts of berries, valued at $191,401. The small-fruits of less importance that were produced in 1909 were: 541,498 quarts of gooseberries, valued at $44,238, 265,858 quarts of currants, valued at $21,863; and 13,418 quarts of cranberries, valued at $1,248.

Of the vegetables produced in Illinois, potatoes are by far the most important. The acreage in 1909 was 138,052, and the production 12,166,901 bushels, valued at $6,401,598. The acreage devoted to sweet potatoes and yams was 10,568, the production being 1,050,932 bushels, valued at $506,760. The acreage devoted to the production of all other vegetables, excluding the potato, sweet potato and yam, was, in 1909, 120,291 and the production was valued at $9,392,296. The leading vegetables, their acreage, and the value of the product were as follows: sweet corn, 19,976 acres, valued at $558,746; onions, 3,315 acres, valued at $546,951; tomatoes, 5,316 acres, valued at $343,132; cabbage, 5,207 acres, valued at $341,161; cucumbers, 2,981 acres, valued at $234,203; watermelons, 6,211 acres, valued at $188,869; asparagus, 2,241 acres, valued at $181,557; 231 acres of lettuce, valued at $153,784. Other vegetables of less importance in 1909 were green beans, beets, cantaloupes and muskmelons, carrots, cauliflower, celery, pop-corn, horse-radish, parsnips, green peas, green peppers, radishes, rhubarb, spinach, and turnips.

The acreage devoted to the growing of flowers and plants has increased from 679 in 1899 to 1,339 in 1909, an increase of 97.2 per cent. The total area covered by glass in 1909 was 15,950,853 square feet, of which 14,380,927 were covered by greenhouses, and 1,569,926 by sashes and frames. The value of the flowers and plants produced in 1909 was $3,694,801, as compared with $1,894,960 in 1899.

The acreage occupied by farms and establishments growing nursery products in 1909 was 3,454, as compared with 3,142 in 1899. The value of the products in 1909 was $822,284, an average value an acre of $238.07.

J. C. Blair.

Michigan.

No state in the Union has greater natural advantages than Michigan (Fig. 2499) and few if any have made more use of them along horticultural lines. Not only are the soil and climate unusually well adapted for the growing of flowers, vegetables and nearly all the deciduous fruits, but excellent shipping facilities are provided.

Almost any kind of soil may be found in every county in the state and often upon the same farm. The sandy-loam soils which are so desirable for peaches, cherries and grapes, are widely distributed, as are somewhat heavier soils for apples, plums, pears and the small-fruits. Even when the soil upon the surface appears so light as to be worthless, a clay subsoil is often found upon which trees of all kinds will grow luxuriantly. Along the shores of Lake Michigan is some of the best fruit-land where the soil is of a sandy nature and absolutely devoid of clay. From this the soil varies through the sandy loams to light and heavy clay loams, to clay soils which when overlying an open subsoil answer well for growing pears, apples and even for the other fruits like peaches, for which it is generally understood that a sandy loam soil is better adapted.

Aside from the nature of the soil itself, the general contour of the land aids in making Michigan a great fruit state. While much of the land is level to the extent of being low and swampy, and still other extensive areas are so steep and rough as to be of little value for the highest type of fruit-culture, a large proportion of the land in nearly every county is gently rolling, with slopes that often extend to points 100 or more feet above the land in the neighboring valleys. This not only provides the needed drainage for water, but favoring the movements of the air, it permits the cold air to pass off to the lower levels, thus lessening the injury from late frosts in the spring as well as from early frosts in the fall, besides making a difference of 5° to 10° in the minimum winter temperatures.

Another horticultural asset of almost inestimable value to Michigan comes from the fact that the state is surrounded on three sides by the waters of the Great Lakes, besides having thousands of inland lakes within her borders. They aid not only in providing almost ideal climatic conditions, but in furnishing quick, cheap and excellent conditions for the transportation of fruit and other perishable products to market.

In addition to the splendid service in the handling of horticultural products provided by the steam and trolley lines, the fruit-grower is favored by the many trans-lake steamship lines, which take the fruit during the night to the market points to which it is consigned in time for the morning market. Not only are there several lines which skirt the eastern shores, but on Lake Michigan there are no less than a dozen lines which take the fruit from twenty or more ports direct to Chicago, Milwaukee and other points, besides a number of minor connecting lines of boats. Besides furnishing regular and comparatively cheap service, the boat-lines make it possible to ship the fruit under almost ideal conditions, in the cool night air of the lake and without the jar and shaking to which it would necessarily be exposed if shipped by rail.

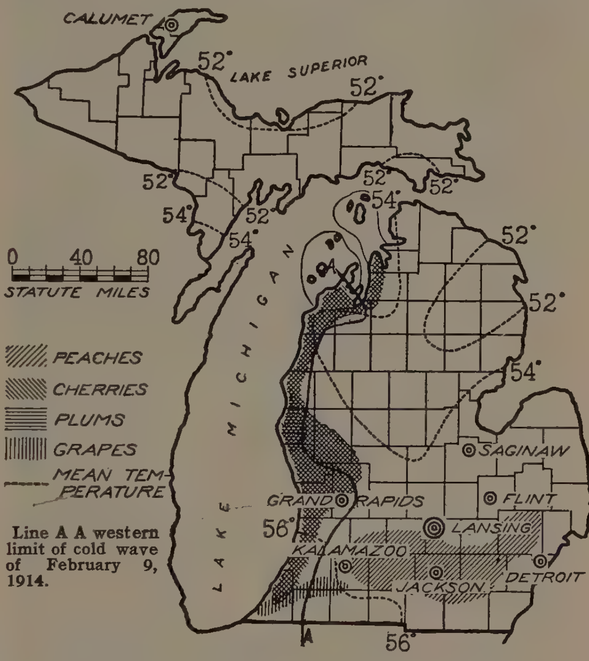
Although in the early times nearly every farm had its home-orchard in which a general variety of fruits was grown, there were very few that could be called commercial orchards, except in the counties bordering upon Lake Michigan. The peach in particular was an exception, and to such an extent that the region from Benton Harbor to Grand Haven was known as the Michigan Fruit-Belt, or Peach-Belt, but it was soon learned that this region by no means included all of the land in Michigan that was suited to commercial orcharding. While by far the larger area is still in the southern half of the lake-shore counties, extensive orchards of the peach and other fruits are now found all along the shore as far north as Charlevoix, and especially about Ludington, Manistee, Frankfort and Traverse City. The planting, however, has not been confined to the counties bordering upon Lake Michigan, some of the largest orchards in the state being in Newaygo, Kent, Barry, Kalamazoo, Oakland, Livingston and other interior counties. The principal requirements being a moderately rich and well-drained soil and a location considerably above the land immediately surrounding it, these can and are being met in nearly every county in the lower peninsula, although there are very few commercial peach orchards in the northern half of the state, except within 20 miles of Lake Michigan.

Plums, also, have been very generally planted, although the acreage is much smaller than that of peaches. The southern lake-shore counties are giving especial attention to this crop, the largest areas being in Oceana, Allegan, Berrien, Mason, Kent, Van Buren and Ottawa counties. Under proper care the crop is a profitable one, but from lack of proper spraying and the resulting loss of the foliage from leaf-blight, many of the trees are seriously injured and often killed by the winter.

While the sour varieties of cherries do well in almost all of the Michigan counties, the northern half of the western lake-shore counties seem to be especially suited to them and very large plantings have been made, particularly about Traverse City, Manistee, Frankfort, Northport and Charlevoix. The same region is also well adapted to the sweet cherry and extensive plantings have been made. The trees seem to be hardy, bear profusely and the fruit readily finds a market at about twice the price of the sour varieties.

Vineyards of considerable extent are found in most of the southern counties, but from a commercial standpoint Berrien and Van Buren counties take the lead, and grapes from the Lawton and St. Joseph grape regions are shipped to nearly every state in the Union. Kent, Cass, Ottawa, Allegan, Monroe, and Kalamazoo counties also have many extensive vineyards.

Nearly every county in the southern peninsula has large commercial apple orchards and nearly three-fourths of them have 100,000 trees or more. Although they are being very generally planted all over the state, the more extensive plantings are along the western border. The largest percentage of increase has been in Manistee, Benzie, Leelanaw, Grand Traverse, Antrim, Charlevoix and Cheboygan counties. Large plantings of the Oldenburg have been made in the more southern counties, this variety for a number of years having been exceedingly profitable.



Line A A western limit of cold wave of February 9, 1914.

2499. Michigan, showing horticultural parts or districts.

While six of the southern lake-shore counties grow more small-fruits than all the remainder of the state these being the only ones which have over 800 acres, there are at least thirty counties in which 100 acres or more are grown. The northern part of the state, including the upper peninsula, is coming to the front with its late varieties of strawberries which come on after the season is over in the southern counties, and these with the "everbearing" kinds make it possible in some seasons to have Michigan-grown strawberries for six months of the year.

As the years go by, the growing of fruit becomes more and more the work of specialists. It has been found that the slipshod methods formerly in vogue will not give results, and with greater attention to the selection of orchard-sites, a better choice of varieties, and with up-to-date methods in caring for and spraying the trees, and in picking, grading and packing the fruit, a new era in Michigan fruit-culture seems at hand.

While the development in fruit-culture in Michigan has been rapid, even greater progress has been made in the cultivation of flowers and vegetables under glass. For the most part the larger commercial greenhouses are located near Detroit or Grand Rapids, but every city and many of the villages have greenhouses used for commercial purposes. The houses of today are twice as large in each of their dimensions as thirty years ago. Michigan also has the first full-sized, portable, commercial greenhouse ever constructed, at Redford, near Detroit.

Equal progress has also been made in the size of the flowers, and many of the varieties of roses, carnations and chrysanthemums developed by Michigan specialists have also doubled. There is a large wholesale trade in all of the above as well as in violets and sweet peas. The florists' plant business is also rapidly increasing. In addition to the local demand, the reputation of the Michigan growers brings orders for chrysanthemum, carnation, rose and geranium plants from all parts of the country. Several gladiolus, dahlia and canna specialists also do a large plant business.

The attention given to the growing of greenhouse vegetables has also increased. At Grand Rapids alone, 1,500,000 square feet of glass are used for this purpose, the business giving employment to 600 men. The loose-leaf, curled variety of lettuce, known as Grand Rapids Forcing, is the only kind used. Three crops are grown each year, the last crop being followed by tomatoes, cucumbers or parsley. The heads are packed in paper-lined barrels and shipped in refrigerator cars to points as far distant as Buffalo, Cincinnati and Louisville.

Many years ago Kalamazoo became known for the fine celery grown there, but there are hundreds of points where an equally fine article is produced today. Many thousand tons are shipped in carload lots and by express all over the country. The soil generally used for this crop is muckland which has been drained, but where the water stands within 2 feet of the surface, thus affording sub-irrigation for the crop. Nearly every city and large town has celery gardens to supply the local demand and many of them do a large shipping business.

There are also many crops commonly classed as garden vegetables which are grown upon such extensive plans as almost to become field-crops. Among them are cabbages, onions, watermelons and muskmelons, garden peas, beans, asparagus, and potatoes. For cabbages and onions, as well as for the growing of celery, the clearing of thousands of acres of swampland has furnished almost ideal conditions, and hundreds of carloads are shipped out of the state after supplying the local demand. There are several "kraut" factories in the state, each of which uses several hundred tons of cabbages.

Michigan also leads all other states in the acreage of garden peas and beans, there being an enormous amount used by the canning factories, besides what are required for local consumption and for shipping in the fresh state. In field beans the crop equals the combined yield of all of the other states, and the yield of potatoes is excelled by few, if any, states.

In addition to the area used for the growing of the above-mentioned crops for food purposes, large tracts are devoted to the production of seeds, the quality of Michigan-grown seed being generally recognized by seedsmen who send there for their supply. It is estimated that not less than 15,000 acres are used for growing seed of garden varieties of peas, 10,000 acres for garden beans, 2,000 acres for sweet corn, with 1,000 acres of cucumbers, 1,000 acres of melons, 500 acres of tomatoes, besides large areas devoted to onion, radish, cabbage and other vegetable seeds.

Reference has been made to the use of peas and beans by canning factories, but they also require immense quantities of other vegetables, such as asparagus, rhubarb, sweet corn, pumpkins, squashes, and tomatoes, to say nothing of the cucumbers, onions, and peppers used for pickling. The length and breadth of the state is dotted with salting and pickling stations, the number being little if any less than one thousand. The canning factories also use hundreds of thousands of bushels of strawberries, raspberries, blackberries, gooseberries, cherries, plums, peaches, pears and apples.

To furnish trees for the orchardists in this and other states, there are more than 100 nurseries, from which trees, shrubs and fruit-plants are sold. Several of the larger nurseries are located at Monroe, in the southeast corner of the state, where the soil seems to be especially adapted for the growing of trees. There are also nearly fifty firms which make a specialty of growing and selling small-fruit plants.

Although one generally thinks and speaks especially of the lower peninsula as the horticulturist's paradise, there is an immense area between Lake Michigan and Lake Superior which presents strong claims for recognition. While the climate is severe for the more tender species and varieties, the hardier kinds of apples, cherries and plums, as well as the small-fruits, do remarkably well. The fruit excels in color and flavor, and this section has a promising future horticulturally.

To mention the men who have done most to promote the horticultural interest of Michigan one would have to write a history of horticulture in nearly every county. B. Hathaway, of Little Prairie Ronde, C. Engle, of Paw Paw, and Geo. Hosford, of Ionia, have been especially successful in developing new varieties of fruit; I. E. Ilgenfritz, of Monroe, L. G. Bragg, of Kalamazoo, and N. P. Husted, of Lowell, were for many years the proprietors of the largest nurseries in the state; R. M. Kellogg, of Three Rivers, worked for years to develop improved strains of strawberries and for better methods of culture; C. D. and G. W. Lawton were pioneers in the grape industry at Lawton; J. G. Ramsdell and George Parmalee did much to develop an interest in fruit-culture in the Grand Traverse region, and L. H. Bailey was for years the leading apple-grower at South Haven. More than anyone else, T. T. Lyon fostered the interests of horticulture in Michigan (see Volume III, page 1585).

Public-service agencies for horticulture.

The Land-Grant College of Michigan is located at East Lansing, and was established in 1855. There are six members of the horticultural staff.

The Experiment Station is also situated at East Lansing and the horticultural force consists of six members. Four or five bulletins on horticultural subjects are published each year. Branch stations, at which considerable attention is given to horticulture, and to fruit-growing in particular, are maintained at South Haven and at Chatham in the upper peninsula.

Extension work is conducted in horticulture, by means of farmers' institutes, extension schools and the like. There are also three men connected with the extension service of the College who give especial attention to horticulture. They are specialists in fruit-growing, the control of insects and diseases, and potato-growing and truck-gardening.

Horticulture forms a part of the curriculum at the state normal schools at Kalamazoo and Mt. Pleasant and at the Menominee and Chippewa county agricultural schools, and is given considerable attention at fifty high-schools which have an agricultural department.

The work of the State Horticultural Society in furthering the horticultural interests should not be overlooked. Established in 1870 as the State Pomological Society, its field of work gradually broadened until 1880 when the name changed to "The State Horticultural Society." There are also in Michigan some twenty local county or district horticultural societies, auxiliary to the State Society. A number of coöperative organizations have been organized for the purpose of providing for a better distribution of fruit, securing improved transportation facilities, shipping in carload lots, and so far as possible selling direct to the retailer. There have been three associations which have handled the grapes in the Lawton district for a number of years to the general satisfaction of the growers, and while some among the other associations have been more or less failures, in many instances excellent results have been attained.

The State Board of Agriculture is in charge of the nursery and orchard inspection and the enforcement of the laws relating to the spraying for dangerous insects and diseases.

Statistics (*Thirteenth Census*).

The approximate land area of Michigan in 1910 was 36,787,200 acres. The land in farms was 51.5 per cent of the land area, or 18,940,614 acres. Of the land in farms, 12,832,078 acres were improved land; 2,927,554 were woodland; and 3,180,982 acres other unimproved land. The total number of farms in 1910 was 206,960. The average number of acres to a farm was 91.5. [The total area is 57,980 square miles.]

The leading agricultural crops of the state are cereals, hay and forage, and forest products of the farms. Cereals, in 1909, occupied 34.4 per cent of the improved land, or 4,415,629 acres. The value of the cereals in 1909 was $70,544,250, or 43.5 per cent of the total value of all crops. Hay and forage, in 1909, occupied 21.2 per cent of the improved land, or 2,715,301 acres, and the value of hay and forage for the same year was $36,040,087, or 22.2 per cent of the total value of all crops. The value of the forest products of the farms in 1909 was $7,911,901, as compared with $7,530,369 in 1899. Sugar beets are also grown extensively, particularly in the "Thumb" section of the state, the acreage increasing from 40,624 in 1899 to 79,195 in 1909, an increase of 94.9 per cent, when the value of the production was $4,032,718.

Horticultural crops grown are fruits and nuts, small-fruits, vegetables including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts grown in 1909 was $10,570,855, as compared with $4,186,549 in 1899. Small-fruits decreased in acreage from 29,197 in 1899 to 21,414 in 1909, a decrease of 26.6 per cent, when the total value was $2,028,865. In 1909 the total acreage of potatoes and other vegetables was 456,368 and their value $16,201,328. The acreage of vegetables, excluding potatoes, was 90,861, an increase of 58 per cent over the acreage in 1899, and the value of these vegetables in 1909 was $6,286,645. Flowers and plants and nursery products increased in acreage from 2,060 in 1899 to 3,736 in 1909, an increase of 81.4 per cent, when their value was $1,786,538.

The total quantity of orchard-fruits produced in 1909 was 15,220,104 bushels, valued at $9,020,842. Apples contributed about four-fifths of this quantity, peaches and nectarines and pears most of the remainder. The number of apple trees of bearing age in 1910 was 7,534,343; those not of bearing age, 2,253,072. The production in 1909 was 12,332,296 bushels, valued at $5,969,080. The peach and nectarine trees of bearing age in 1910 numbered 2,907,170; those not of bearing age, 2,991,090. The production in 1909 was 1,686,586 bushels, valued at $1,700,330. The number of pear trees of bearing age, in 1910 was 1,136,151; those not of bearing age 623,931. The production in 1909 was 666,023 bushels, valued at $535,771. The production of cherries in 1909 was 338,945 bushels, valued at $590,829; that of plums and prunes 181,188 bushels, valued at $205,765; and that of quinces 13,484 bushels, valued at $16,858.

The production of grapes in 1909 was 120,695,997 pounds, as compared with 41,530,369 pounds in 1899. The value of grapes in 1909 was $1,531,057. The grapevines of bearing age in 1910 numbered 11,013,576; those not of bearing age, 1,869,648.

The total production of nuts in 1909 was 961,137 pounds, valued at $18,956. Most of the nuts consisted of black walnuts, hickory-nuts, and chestnuts, there being 546,779 pounds of black walnuts produced, valued at $7,804; 276,015 pounds of hickory-nuts, valued at $6,681; 112,488 pounds of butternuts, valued at $1,552; and 23,369 pounds of chestnuts, valued at $2,762.

Strawberries are by far the most important of the small-fruits raised in Michigan, with raspberries and loganberries, and blackberries and dewberries ranking second and third respectively. The acreage of strawberries decreased from 10,837 in 1899 to 8,051 in 1909, when the production was 14,218,768 quarts, valued at $1,000,788. The acreage of raspberries and loganberries decreased from 10,193 in 1899 to 8,786 in 1909, when the production was 8,381,943 quarts, valued at $695,019. The acreage of blackberries and dewberries also decreased from 4,385 in 1899 to 2,973 in 1909, when the production was 3,075,954 quarts, valued at $218,174. There were also produced 768,259 quarts of currants, valued at $58,288; 403,680 quarts of gooseberries, valued at $28,932; and 125,536 quarts of cranberries, valued at $6,992.

Of the vegetables, potatoes are by far the most important. The acreage increased from 311,963 in 1899 to 365,483 in 1909, when 38,243,828 bushels were produced, valued at $9,913,778. Dry edible beans are grown in Michigan also. In 1909 the acreage was 403,669, from which were harvested 5,282,511 bushels, valued at $9,716,315. Dry peas were produced to the amount of 1,162,403 bushels, valued at $1,337,430. Other vegetables of importance grown in 1909 were: 2,850 acres of celery, valued at $488,610; 7,061 acres of cucumbers, valued at $342,042; 4,314 acres of cabbage, valued at $257,144; 2,850 acres of tomatoes, valued at $217,256; 5,726 acres of sweet corn, valued at $147,762; 1,829 acres of cantaloupes and muskmelons, valued at $146,801; 1,130 acres of onions, valued at $146,507; and 4,548 acres of green peas, valued at $102,263. Vegetables of lesser importance were asparagus, green beans, beets, carrots, cauliflower, pop-corn, horse-radish, lettuce, parsnips, green peppers, radishes, rhubarb, rutabagas, squash, turnips and watermelons.

The acreage devoted to the production of flowers and plants increased from 220 acres in 1899 to 702 in 1909, an increase of 219.1 per cent. The total area under glass in 1909 was 4,122,099 square feet, of which 3,922,772 were covered by greenhouses and 199,327 by sashes and frames. The value of the products in 1909 was $1,143,764.

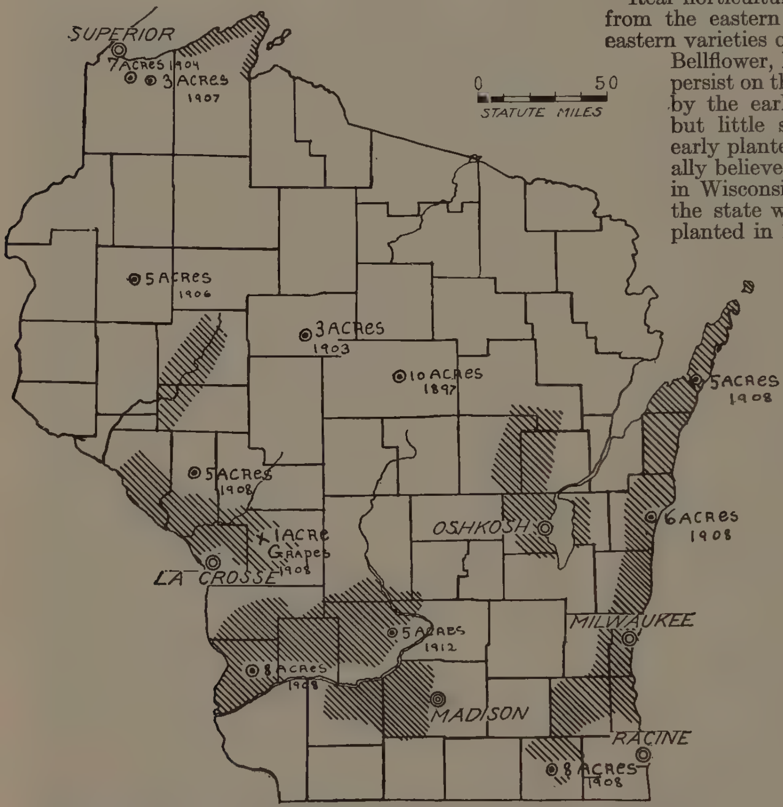
The acreage devoted to nursery products increased from 1,840 in 1899 to 3,034 in 1909, an increase of 64.9 per cent, when the value of the nursery products was $642,774.

L. R. Taft.

Wisconsin.

The surface of the state of Wisconsin (Fig. 2500) is, in general, one of low relief. The lowest parts are about 600 feet and the highest nearly 2,000 feet above sea-level. In the southwest quarter of the state—the unglaciated part—differences in elevation from 200 to 500 feet within a distance of a mile or two are common, and the area is hilly in general. In this hilly part of the state, the drainage is perfect. There are no swamps or lakes, and, while the soil in some parts is sandy, it is mostly a rich clay and loam derived from the decay of limestone. In the glaciated part of the state the surface is undulating, local relief of more than 100 feet being uncommon. The drainage is characteristic of glacial areas, being poorly developed, so that there are numerous marshes and small lakes. The soil presents all variations in character, but is mostly very fertile.

According to Whitson and Baker, the mean annual temperature of the state is 43.3°, varying from 48° for the southwest corner to 39° for the northeastern part. Acccording to the seasons, the mean temperature is as follows: Winter, 17°; spring, 42°; summer, 67°; fall, 47°. "Southern Wisconsin has a summer temperature similar to that of central France, southern Germany and the Danube Valley, while northern Wisconsin is about as warm in summer as London or Berlin. The winter temperature of the state, however, resembles that of Sweden and central Russia. The length of time from frost to frost varies widely, ranging from 175 to 75 days. Thus, the length of the frostless period at Beloit and Madison is as long as in the higher hills of Georgia or the Valley of Virginia. It is worthy of note that the growing season at both Bayfield and Sturgeon Bay is longer than that at North Yakima, Washington, and Hamilton, Montana, and equal to that at Montrose; while the season at Milwaukee and Madison is about the same as at Rochester, New York."



2500. Wisconsin, to show horticultural regions; the point-circles indicate location and acreage of trial orchards maintained by the State Horticultural Society.

Wisconsin has an average yearly rainfall of 28 to 34 inches, about one-half of which is in May, June, July and August, and 70 per cent April to September.

Any survey of horticulture in Wisconsin must include an outline at least of its history, for the development or rather the evolution of horticulture in Wisconsin constitutes one of the most interesting chapters in the annals of American horticulture.

In the middle western states, orchards and gardens simply moved westward from their original homes along the Atlantic coast and are now merely replicas of the parent orchards and gardens. The Baldwin apple and the Flemish Beauty pear, standards in Massachusetts and New York, are likewise standards in Ohio, Indiana and Michigan. Horticulture in these states has been and is now merely an extension of horticulture in the eastern states. In Wisconsin and the upper Mississippi Valley, it has been an evolution.

The first gardens in Wisconsin, planted by civilized people, were at Green Bay and on Madaline Island, one of the Apostle group. At these places the Jesuit missionaries or their followers planted gardens, not alone of vegetables but seeds of the apple and cherry. Along the shores of Madaline Island may still be found thickets of cherry, offspring of the seedling trees planted by the missionaries.

Real horticulture dates from the coming of settlers from the eastern states, 1830 to 1840, who brought eastern varieties of apples, such as Baldwin, Greening, Bellflower, King and others. These did not long persist on the black alluvial soils first preëmpted by the early settlers; long winters, often with but little snow, soon wiped out most of the early planted orchards until it came to be generally believed that tree-fruits could not be grown in Wisconsin. The rougher broken sections of the state were settled later, and here orchards planted in 1845 to 1855 still stand.

The introduction of the Russian varieties was the cause of another set-back, at least delaying the development of commercial horticulture in Wisconsin for a generation. The Russian apples all proved hardy enough but also proved generally worthless. Something of value resulted, as there have been saved as standard sorts Duchess, Astrachan, Longfield, Yellow Transparent and a few others, but the loss was greater than the gain.

During these two periods, however, there were many earnest men who were not content to wait but, by planting seeds, picking up strays from fence-corners, testing, discarding, created, as a result of fifty years' effort, a new race of fruits belonging to the state and a part of it. The inhabitants of the upper Mississippi Valley owe almost all their horticulture to the tireless, painstaking efforts of these pioneers.

The following fruits, all recognized as standards in Wisconsin and Minnesota and many of them adopted by other fruit sections, were all originated in Wisconsin: Apples—Gem, Newell, Plumb Cider, McMahan, Northwestern Greening, Windsor, Milwaukee, Pewaukee, Wolf River. Crabs—Brier, Gibb. Plums—De Soto, Springer. Grapes—Janesville. Blackberries—Ancient Briton, Stone. Raspberries—Loudon. Strawberries—Jessie. From Minnesota, Wisconsin growers have the Wealthy; from Iowa, the Patten Greening; and from Maine, the Dudley apples.

The period of evolution occupied fully fifty years from the forties to the nineties and was almost wholly confined to amateur lines, the home orchard and garden. In the past ten years the business of growing fruit for market has developed very rapidly. While in 1902, a 60-acre apple orchard was the largest in the state, orchards of 75 to 100 acres are not now uncommon.

The principal orchard sections of the state comprise parts of Bayfield, Door, Chippewa, Waupaca, Sauk, Richland, and Crawford counties in addition to the counties south of Door bordering on Lake Michigan. Some of the best apple lands in the state are to be found on the ridges bordering the valley of the Kickapoo River in Crawford County. These unglaciated ridges extend from Wauzeka to La Farge, west to the Mississippi and east to Richland County. Several thousand acres of commercial apple orchards are now being developed in this section. Probably the most remarkable phase in the development of commercial horticulture in Wisconsin is the extensive planting of tree-fruits in Door and Bayfield counties, both north of the 45th parallel. The acreage of tree-fruits at the present time in Door County exceeds 7,500 largely sour cherries, including one plantation of 670 acres of Montmorency and Early Richmond. The Bayfield district comprises a narrow strip along the shore of Lake Superior from 2 to 5 miles wide and extending north and west from Washburn to the east line of Douglas County. Over 600 acres of apples and cherries are now planted here in addition to an equal or greater acreage of small-fruits. The success of fruit-growing in these districts is clearly due to the modifying influence of lakes Superior and Michigan.

Pears are not extensively grown in Wisconsin on account of lack of hardiness of the tree as well as the ravages of fire blight.

The americanas are the only plums that can be depended upon to bear fruit regularly in all parts of Wisconsin. The hardier sorts of the European plum, *Prunus domestica*, and of the Japanese plum, *Prunus triflora*, are fairly fruitful in the eastern part, notably in Door and Kewaunee counties. The trees of the last two species, as of those of *Prunus hortulana* and *Prunus angustifolia*, endure the winters throughout the state, but the flower-buds are destroyed whenever the thermometer registers much lower than 20° below zero.

The peach and apricot are not fruitful in any part of Wisconsin except after unusually mild winters. The trees are frequently grown in gardens, and sometimes attain considerable size, but they freeze back more or less in the average winter. Trees of the apricot, imported from Russia, have been frequently planted in Wisconsin, by way of experiment, but are nowhere fruitful. Even if the flower-buds escape destruction, the fruit almost invariably falls soon after setting.

The grape, with winter protection, is successfully grown throughout southern and eastern Wisconsin, when planted on light soil, with southern exposure.

Strawberries and other small-fruits are grown in sufficient quantities to supply local markets and, in addition, from 250 to 300 carloads are shipped annually to Minnesota and the Dakotas, mainly from Sturgeon Bay, Bayfield and Sparta.

Huckleberries and blueberries are extensively gathered from wild plants in certain parts of west-central Wisconsin, and are shipped in large quantities to cities of the Northwest. Wisconsin is one of the chief cranberry-producing states. In parts of Wood, Adams, and Juneau counties, and in less degree in Waupaca and Green counties, the cranberry plant was native over very large areas, and before the settlement of the country the Indians gathered the fruit extensively in bearing years. Latterly, the wild marshes have been largely improved by clearing and providing flooding facilities. In some seasons the total output of cranberries from Wisconsin has aggregated nearly 100,000 barrels. The varieties grown are mostly native, and the quality and keeping of the fruit are excellent. In the years 1894 and 1895, the cranberry industry of Wisconsin suffered a serious check by the destruction of many marshes by fire during an exceptionally dry period. But the business is rallying and may, in a few years, recover its former magnitude.

The trucking industry is confined largely to the southeastern part of the state, mainly Racine, Kenosha and Milwaukee counties.

Wisconsin is one of the leading cabbage-producing states of the country, shipping annually over 5,000 carloads of the hard winter varieties. Domestic cabbage are also produced in large quantities for the manufacture of kraut. The principal producing counties are: Brown, Columbia, Kenosha, LaCross, Milwaukee, Outagamie, Pierce, Racine, Rock, St. Croix, and Wood. Outagamie is probably the heaviest producer, about 40,000 tons being the annual production of recent years. Within the past few years the cabbage industry of the southeastern part of the state has been threatened with destruction, owing to the ravages of a relatively new disease known as "yellows." By selection, a disease-resistent strain of winter cabbage has been secured which stands up almost perfectly under the most adverse disease conditions. This strain has been distributed under the name "Wisconsin Hollander." Further trials show that similar disease-resisting strains of the other commercial types are obtainable.

The onion industry of Wisconsin centers along the lake shore in Kenosha, Racine, and Milwaukee counties, and is extending into other sections. The types of onions usually grown are the Red and Yellow Globe, although the white onions are raised to a certain extent. The land best adapted for this crop is rather limited, about 600 acres being raised annually at the present time. Owing to the profitableness of this crop, the acreage is tending to increase. The yield to the acre varies greatly with the fertility of the soil and the care given the plants in their early growth. The average yield is above 400 bushels an acre with occasional yields running over 700 bushels. With fair market conditions, the growers receive $200 to $500 an acre.

Forty-three per cent of all canned peas in the United States are produced in Wisconsin. In 1909, this state produced 1,165,055 bushels of dry peas, more than any other state.

Coincident with the extension of fruit-planting has come the development of selling organizations. Fruit-selling associations, purely coöperative in character, have been in successful operation for several years at Sparta, Sturgeon Bay and Bayfield.

In esthetic horticulture Wisconsin compares favorably with any other state. The park systems of the larger cities receive liberal support both from the municipalities and private gifts. About Geneva Lake, in the southeastern part of the state, are the summer homes of many wealthy persons, largely residents of Chicago. Here may be found some excellent examples of landscape art and architecture.

Public-service agencies for horticulture.

The College of Agriculture is located at Madison. The Department of Horticulture was organized in 1889, and is one of the most potent forces in the development of horticulture in the state. There are eight teaching members of the horticultural staff.

The Experiment Station is also at Madison. The research work is varied, dealing with particular problems in the culture of the various horticultural crops. Most of this work is carried on at Madison but a portion of it is done in connection with the work at the branch stations. Considerable work has been done with variety testing of fruits.

The extension service is of more recent development. Three members of the staff give most of their time to this line of work. The organization of community centers for the growing of pure potato seed stock, inspection and certification of potatoes, orchard rejuvenation, spraying demonstrations, tobacco seed-bed sterilization, home and school ground improvement, lectures and garden and fruit schools are some of the lines of activity of the department.

The office of State Entomologist was created in 1915, and has sole charge of the nursery and orchard inspection, the inspection of apiaries and the examination and analysis of insecticides and fungicides. This office is also authorized to engage in extension work.

The Wisconsin State Horticultural Society, organized in 1865, and chartered by the state in 1871, maintains a bureau of information and answers all questions on fruit-growing submitted to the secretary. In addition, the Society maintains ten trial orchards or demonstration stations for the purpose of testing the adaptability of varieties to the soils and climates of these particular regions. In addition to its annual report, it issues a monthly magazine "Wisconsin Horticulture." This Society is purely an educational institution and its purpose is the advancement of every branch of horticulture in the state.

Statistics (*Thirteenth Census*).

The approximate land area of Wisconsin in 1910 was 35,363,840 acres. The land in farms was 59.6 per cent of this area, or 21,060,066 acres. Of this land in farms, the improved land numbered 11,907,606 acres; the woodland, 5,377,580 acres; and other unimproved land in farms, 3,774,880 acres. The number of all the farms in 1910 was 177,127, and the average acreage to a farm, 118.9. [The total area is 56,066 square miles.]

The leading agricultural crops grown in Wisconsin are cereals, hay and forage, and tobacco. Cereals decreased in acreage from 5,376,944 in 1899 to 4,951,066 in 1909, when the production was valued at $73,141,919, or 49.3 per cent of the total value of all crops. Hay and forage increased in acreage from 2,397,982 in 1899 to 3,079,102 in 1909, when the production was valued at $40,866,396, or 27.5 per cent of the total value of all crops. Tobacco increased in acreage from 33,830 in 1899 to 40,458 in 1909, when the production was valued at $3,855,033. The value of the forest products of the farms in 1909 was $9,559,428, as compared with $6,116,033 in 1899.

Horticultural crops grown in Wisconsin are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $2,130,935, as compared with $284,024 in 1899. Small-fruits decreased in acreage from 12,389 in 1899 to 6,305 in 1909, when the production was 9,782,779 quarts, valued at $765,437. The total acreage of potatoes and other vegetables in 1909 was 360,312, and their value, $12,511,816. Excluding potatoes, the acreage of other vegetables increased from 39,578 in 1899 to 70,123 in 1909, when the production was valued at $4,593,865. Flowers and plants and nursery products increased in acreage from 930 in 1899 to 1,007 in 1909, when the production was valued at $893,866.

The total quantity of orchard-fruits produced in 1909 was 2,343,517 bushels, valued at $2,087,202. Apples contributed about 95 per cent of this quantity, and cherries most of the remainder. Apple trees of bearing age in 1910 numbered 2,430,232; those not of bearing age, 1,408,726. The production in 1909 was 2,232,112 bushels, valued at $1,896,681. The number of cherry trees of bearing age in 1910 numbered 290,495; those not of bearing age, 148,775. The production in 1909 was 81,340 bushels, valued at $152,119. The production of other orchard-fruits in 1909 was: 15,907 bushels of plums and prunes, valued at $20,944; 12,992 bushels of pears, valued at $16,551; 956 bushels of peaches and nectarines, valued at $552; 100 bushels of apricots, valued at $211; and minor quantities of quinces and mulberries.

The production of grapes in 1909 was 701,329 pounds, valued at $25,537. The vines of bearing age in 1910 numbered 148,348; those not of bearing age, 63,098.

The total production of nuts in 1909 was 609,428 pounds, valued at $18,196. The nuts contributing to this production were: 496,722 pounds of hickory-nuts, valued at $15,954; 86,086 pounds of black walnuts, valued at $1,617; and 20,310 pounds of butternuts, valued at $450.

Strawberries are the most important of the small-fruits produced in Wisconsin, with cranberries second in importance. The acreage of strawberries decreased from 3,508 in 1899 to 2,863 in 1909, when the production was 5,188,117 quarts, valued at $434,971. Cranberries decreased in acreage from 5,821 in 1899 to 1,689 in 1909, when the production was 2,549,344 quarts, valued at $127,212. Raspberries and loganberries decreased in acreage from 1,616 in 1899 to 964 in 1909, when the production was 1,053,889 quarts, valued at $114,578. Other small-fruits produced were: 498,119 quarts of blackberries and dewberries, valued at $48,707; 383,982 quarts of currants, valued at $31,078; and 107,708 quarts of gooseberries, valued at $8,751.

Potatoes, the most important of the vegetables in Wisconsin, increased in acreage from 256,931 in 1899 to 290,185 in 1909, when the production was 31,968,195 bushels, valued at $7,917,754. The production of the most important of the other vegetables was: 10,506 acres of cabbage, valued at $686,296; 11,182 acres of green peas, valued at $321,324; 650 acres of onions, valued at $95,595; 3,789 acres of sweet corn, valued at $83,502; 1,563 acres of cucumbers, valued at $82,735; 363 acres of tomatoes, valued at $42,300; 137 acres of celery, valued at $36,570; 187 acres of cantaloupes and muskmelons, valued at $25,591; 685 acres of turnips, valued at $19,888; 497 acres of green beans, valued at $16,067; 87 acres of asparagus, valued at $11,498; and 168 acres of watermelons, valued at $11,355. Vegetables of less importance are beets, carrots, cauliflower, popcorn, horse-radish, radishes, rutabagas, and spinach.

The acreage devoted to the production of flowers and plants increased from 194 in 1899 to 252 in 1909. The total area under glass in 1909 was 2,007,310 square feet, of which 1,875,858 were covered by greenhouses and 131,452 by sashes and frames. The value of the flowers and plants produced in 1909 was $592,839, as compared with $270,872 in 1899.

Nursery products increased in acreage from 736 in 1899 to 755 in 1909, when the products were valued at $301,027, as compared with $85,087 in 1899.

FREDERIC CRANEFIELD.

WEST NORTH CENTRAL STATES.

Minnesota.

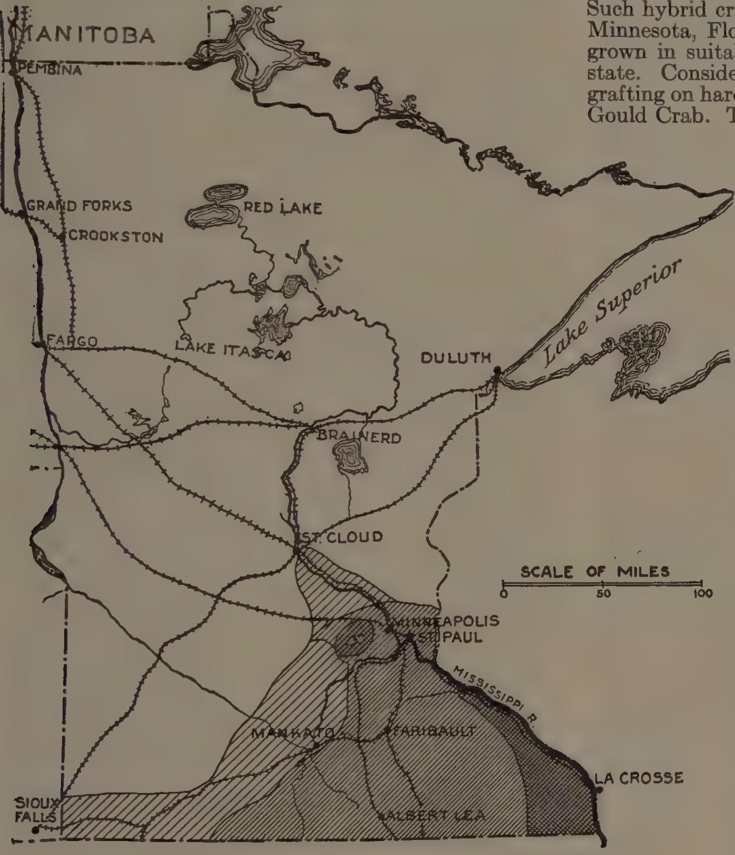
The surface of Minnesota (Fig. 2501) is gently undulating, except in the extreme northwestern part, where, in the Red River Valley, are large, fertile, level prairies. Its roughest agricultural land is found in the eastern part, along the Mississippi River, and in many places the bluffs reach a height of 400 feet above the valley. About one-half the state, embracing the northeastern and eastern parts, was originally heavily timbered, and much timber still remains in the northeast, while many scattered groves of timber will be found elsewhere, especially along the rivers.

There are many lakes, the number of which has been estimated at 10,000. These lakes and the timber in the northern part of the state afford excellent camping-grounds and are visited by thousands of people from the cities of the state and from many states farther south. They are especially numerous in the central and northern parts, where they greatly modify the climate of lands in their vicinity. There are great variations of climate between the extreme northern half, where the summers are very short, and the southern half, where killing frosts seldom occur before the first of October. The winters are generally pleasant, but occasionally severe, and 40° below zero is sometimes experienced.

The soil is generally rich and well adapted to a variety of crops, but it is very variable, and there are some extended areas in the northern part where there is much sandy land that should never be used for agriculture, but should rather be devoted to forestry or turned into forest and game preserves. The undulating surface, variety of good soil and vegetation, and abundance of lakes, afford many very picturesque and beautiful locations for successful horticulture.

The annual precipitation averages about 25 inches, and is well distributed during the growing season. The snowfall is light, and what falls remains usually during the winter. The spring usually opens early, and the transition from winter to spring is very rapid. The soil at St. Paul and southward can generally be worked by April 15, and frequently earlier. The summers and autumns are bright and sunny, and vegetation grows with great rapidity.

Currants, gooseberries, raspberries, blackberries, strawberries, juneberries, americana plums, and the frost or river-bank grapes are native fruits that are found wild in abundance in favorable locations throughout the state. Most of the well-known cultivated sorts of the five species first named do well under cultivation, and large quantities are raised for home consumption and are profitably marketed. The Concord, Worden, Delaware, and grapes of similar character, are easily raised in the many good locations along the lake shores and the river bluffs, and this is an important industry, notwithstanding the fact that the grapes have to be covered in winter, which adds somewhat to the expense of culture. However, on account of the peculiar adaptability of the Delaware grape to some of the soils and to the climate, it is raised with profit in competition with the growers of the eastern states, though the Concord is not high enough in price by one cent a pound to permit of this to any great extent.



2501. Minnesota, showing the best developed horticultural parts.

Apples are raised on a commercial scale in southern and eastern Minnesota, the high, rolling land in the southeastern part being especially well adapted to their cultivation. The varieties of the eastern and central states generally prove a failure here. The Duchess of Oldenburg is the standard of hardiness in apples, and can be grown successfully in good locations as far north as St. Paul, and in a small way 100 miles farther north. The Talman Sweet is raised to some extent, but is liable to suffer in severe winters. The Minnesota seedling apple known as the Wealthy is generally the most profitable kind grown. (See *Gideon*, page 1577.) A great many Russian varieties were formerly planted, but have proved unsatisfactory in most cases and very few are now grown. The hardiest variety of this origin so far found is the Hibernal, which represents a class of sour autumn apples that will thrive on suitable soil in almost any part of the state. The Charlamoff is another very hardy early autumn apple of the same class. Such hybrid crabs as the Transcendent, Gideon No. 6, Minnesota, Florence and Lyman, may be successfully grown in suitable locations and soil over most of the state. Considerable attention is being given to top-grafting on hardy stocks, such as Virginia, Hibernal and Gould Crab. This has proved a good method in many parts of the state and in the northern part appears to be the best way to establish apple orchards. Some good-sized apple orchards are found along the Mississippi River in southeast Minnesota and in the Lake Minnetonka regions. The fruit associations about Lake Minnetonka alone do a business of $50,000 to $75,000 a year.

The americana class of plums is found growing wild all over the state, and the fruit is gathered in large quantities. The cultivated sorts of this class are easily grown everywhere. Wild plums can generally be obtained in abundance in autumn at about $1.50 a bushel. There is no variety of any other class of plums that is appreciably cultivated, although in very favorable locations a few of the Japan and domestic sorts are grown.

Cherries may be successfully grown on a large scale in extreme southeastern Minnesota, and there are some commercial orchards there, but generally throughout the state the fruit-buds are so injured in winter that the trees are unproductive, although they may make a very satisfactory tree growth.

Pears usually blight to death early, and there is no variety that is generally cultivated. Several of the Russian pears are as hardy as the Duchess apple, but they have died, so far as they have been tried, from blight before becoming very productive. Apricots are not sufficiently hardy.

The most common injury to trees is known as sunscald of the trunks, which often causes severe loss. It is easily avoided by shading the trunks. Blight seriously injures some varieties of apples. Winter-protection of various kinds is important and carefully attended to by the best horticulturists.

Vegetables of all the kinds grown in the northern states are very easily raised, and the display of these products in the large markets is excellent. Cabbage, cauliflower, celery, peas, lettuce, potatoes, beans, corn, cucumbers, tomatoes, squash, watermelons, muskmelons and eggplant are to be had in abundance, and the markets are often glutted with them. Native muskmelons and tomatoes occasionally retail at 10 to 15 cents a bushel. The canning of vegetables is becoming an important industry at several points. The climate seems to be especially favorable to vegetables, and there is much less trouble from disease than in many more humid sections. There are two vegetable-growers' associations in the state. The Minneapolis and St. Paul associations, which have a membership of over 200, have been very instrumental in getting a more uniform and better grade of produce on the market. While they do not attempt to set the price of produce. they have proved of much value to the trucking interests both in raising and marketing produce.

One of the important crops of the state is potatoes. These are grown quite largely in the Red River Valley and in the section of country north and northeast of Minneapolis nearly to Duluth. Large quantities are shipped South and West for seed purposes. Special potato organizations have taken hold of the work and are building an important business.

The growing of vegetables under glass has increased greatly in the past few years. Lettuce, tomatoes, and cucumbers are the principal crops grown under glass, although mint, cress, radishes, and parsley are grown to some extent, and find a ready market. A number of larger growers have installed irrigation systems in their greenhouses and find them very satisfactory. They are also used to some extent for outdoor crops. Probably $800,000 to $1,000,000 is invested in the business.

Mushrooms for market are grown to a considerable extent about the Twin Cities. One of the largest pure-culture mushroom-spawn plants in the country is located in St. Paul. This same plant grows large quantities of mushrooms for market.

There are something over 100 nurseries in Minnesota, totaling about 3,000 acres of land and ranging in size from an acre or less to 250 or 300 acres of actual nursery stock. Large importations of bulbs and plants are made from Europe and from outside the state each year. Up to the present time, much of the nursery stock except fruit has been propagated outside the state. With the advent of more greenhouses in connection with the business, much more stock is now propagated at home. Nearly all nurseries doing a large business have established landscape-gardening departments to handle their increasing work along ornamental lines. A number of nurseries have been established specializing only in ornamental shrubs, peonies, iris and perennials.

The demand for ornamental horticulture is considerable and rapidly increasing, giving investment to at least $1,000,000 in the greenhouse business, besides large quantities of flowers and plants purchased outside the state and sold through retail flower-stores. Carnations, violets and chrysanthemums are grown in large quantities. A limited amount of sweet peas, snapdragons, and the like, are also grown and easily disposed of. Large quantities of bulbs, such as tulips, narcissi, and Easter lilies, are forced principally for Christmas and Easter. Roses and some other flowers are brought in from growers outside of the state to a considerable extent, although there are a number of large growers in the state. Peonies, dahlias, asters, sweet peas and iris are grown in large quantities outside for cut-flowers. The demand for these has developed a number of specialists who supply the very best class of material. Minneapolis and St. Paul each have strong florist associations.

The love for horticulture is also shown by the immense sums spent by the cities and small towns for public parks. Minneapolis alone has 3,800 acres of city parks, 50 miles of drives and 1,305 acres of lake surface. St. Paul, Duluth, and other cities and towns of the state will easily bring the park acreage up to 8,000 or 10,000 acres. Besides this, there are three or four state parks, containing something over 1,000 acres, and about 44,000 acres of forest reserve, a part of which is used as a natural public park or playground. These parks are visited by several millions of persons each year, and undoubtedly exert much influence.

Public-service agencies for horticulture.

The University of Minnesota is at Minneapolis, and in 1869 the Department of Agriculture was established at St. Anthony Park about 3 miles from the main campus. Here are located the Experiment Station, School of Agriculture, and College of Agriculture. Although the Agricultural Department was established in 1869, it was not of much importance until about 1885, when a part of the present farm was purchased and the first School of Agriculture established in 1889. There are sub-stations at Crookston, Morris, Grand Rapids, Waseca, and Duluth. A trial fruit station is maintained at Owatonna. This was originally used for raising apple seedlings, but this work has now been taken over by the Fruit Breeding Farm at Excelsior and the Owatonna Station is used only as a trial station.

Schools of agriculture are maintained at Crookston and Morris, in which horticulture is taught to some extent. Horticulture is taught in most of the high-schools in the state having agricultural courses. School-gardens and nature-study classes in some form or other are to be found in nearly all schools.

The Extension Division of the Agricultural Department has a horticulturist who holds institutes, short course lectures, and demonstrations in horticulture throughout the state. Members of the regular Station staff aid in this work to some extent.

Several hundred farmers' clubs scattered throughout the state are aiding in the spread of better agricultural methods. Many of these clubs have special horticultural programs and committees and study horticultural problems systematically.

The Minnesota State Horticultural Society is a very strong and popular organization. Great interest is taken in the raising of seedling apples, and at some of the state fair meetings more than 300 separate varieties of Minnesota origin have been shown. A number of years ago $1,000 was offered for a seedling winter apple, especially adapted to Minnesota conditions. No one has yet been able to claim the prize. One hundred dollars is offered as a prize for a seedling plum of certain qualities, and about $1,000 in prizes are offered for the encouragement of apple-growing. The Society has some eight or ten trial stations operated in different parts of the state at which new fruits, flowers, and so on, are tested. Through the reports of the superintendents of these stations, a fair index of the value of a plant for general use may be obtained. There are a number of local horticultural societies in the state besides a state florist society, which affiliate with the State Horticultural Society. There are also two or three vegetable associations.

The legislature of 1907 appropriated $16,000 for buying land for a fruit-breeding farm. Near Excelsior, 77.89 acres were purchased and equipped with greenhouse, house, storage-cellar, barn and other buildings. Large numbers of seedling strawberries, plums, raspberries and apples are being grown there. The seedling apples are just beginning to fruit, but very promising seedling plums, strawberries and raspberries have already been produced and are distributed over the state. Excellent results have been obtained and its usefulness is just beginning. Nearly the whole acreage is now in seedling fruits bred at this farm.

Statistics (*Thirteenth Census*).

In 1910 the approximate land area of Minnesota was 51,749,120 acres. The land in farms was 27,675,823 acres, or 53.5 per cent of the land area. Of the land in farms 19,643,533 acres were improved; 3,922,391 acres were in woodland; and 4,109,899 acres were unimproved. The number of all the farms in the state in 1910 was 156,137. The average acreage to a farm was 177.3. [The total area of the state of Minnesota is 84,682 square miles.]

The leading agricultural crops are cereals, hay and forage, and forest products of the farms. In 1909, 51.6 per cent of the improved land, or 10,139,850 acres were occupied by cereals and the valuation of the production was $140,864,148, which was 72.8 per cent of the total value of all the crops. The acreage of hay and forage increased from 3,157,690 in 1899 to 3,946,072 in 1909, an increase of 25 per cent, when the production was valued at $26,724,801, or 13.8 per cent of the total value of all crops. The value of the forest products of the farms in 1909 was $5,181,508, as compared with $2,602,335 in 1899. In 1909 flaxseed was produced to the amount of 3,277,238 bushels, valued at $4,863,328.

The horticultural crops produced were fruits and nuts, small-fruits, vegetables including potatoes, flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $813,971, as compared with $125,240 in 1899. Small-fruits increased in acreage from 3,092 in 1899 to 3,738 in 1909, when the production was 4,476,575 quarts, valued at $493,406. In 1909 the total acreage of potatoes and other vegetables was 269,713 and their value $11,044,391. Excluding potatoes, the acreage of the other vegetables was 46,021, and their value $3,359,052, both acreage and value being materially greater than in 1899. Flowers and plants and nursery products increased in acreage from 1,270 in 1899 to 4,017 in 1909, when the value of their products was $1,466,949.

The total quantity of orchard fruits produced in 1909 was 1,066,659 bushels, valued at $801,112. Apples contributed 97.9 per cent of this quantity, and plums and prunes most of the remainder. The apple trees of bearing age in 1910 numbered 1,380,396; those not of bearing age, 1,571,816. The production in 1909 was 1,044,156 bushels, valued at $769,114. The plum and prune trees of bearing age in 1910 numbered 233,736; those not of bearing age, 167,926. The production was 19,920 bushels, valued at $27,808. Other orchard-fruits produced in 1909 were 1,526 bushels of cherries, valued at $2,973; 559 bushels of peaches and nectarines, valued at $659; 400 bushels of pears, valued at $465; and apricots, quinces and mulberries in minor quantities.

Grapes were produced to the amount of 293,805 pounds in 1909, valued at $11,021. In 1899 the production of grapes was 573,272 pounds. The number of vines of bearing age in 1910 was 61,916; those not of bearing age, 35,950.

The nut industry is not an important one in Minnesota, the total production in 1909 being 81,555 pounds, valued at $1,838. The most important of the nuts is the black walnut which produced in 1909, 65,074 pounds, valued at $1,490. Other nuts which are growing in Minnesota in very limited quantities are the butternuts, hickory-nuts, chestnuts and others of more or less importance.

Of the small-fruits grown in Minnesota, strawberries are by far the most important, with the different raspberries ranking next. The acreage of strawberries increased from 1,302 in 1899 to 1,873 in 1909, when the production was 2,730,099 quarts, valued at $268,772. The acreage of raspberries and loganberries increased from 1,115 in 1899 to 1,388 in 1909, when the production was 1,340,469 quarts, valued at $178,689. Other small-fruits produced in 1909 were 182,825 quarts of currants, valued at $19,783; 139,741 quarts of blackberries and dewberries, valued at $17,696; 60,661 quarts of gooseberries, valued at $6,412; and 22,112 quarts of cranberries, valued at $1,981.

Of the vegetables, potatoes far exceed any of the others. The acreage of potatoes increased from 146,659 in 1899 to 223,692 in 1909, when the production was 26,802,948 bushels, valued at $7,685,259. The more important of the other vegetables produced were 1,099 acres of onions, valued at $182,069; 2,315 acres of cabbage, valued at $128,430; 4,697 acres of dry edible beans, valued at $124,996; 2,829 acres of sweet corn, valued at $62,387; 1,190 acres of cucumbers, valued at $59,512; 499 acres of tomatoes, valued at $52,631, and 453 acres of cantaloupes and muskmelons, valued at $41,913. Vegetables of minor importance were asparagus, green beans, beets, carrots, cauliflower, celery, pop-corn, lettuce, green peas, radishes, rhubarb, squash and watermelons.

The acreage devoted to flowers and plants increased from 143 in 1899 to 163 in 1909, an increase of 14 per cent. The total area under glass in 1909 was 1,419,196 square feet, of which 1,332,758 were covered by greenhouses, and 86,438 by sashes and frames. The value of flowers and plants produced in 1909 was $603,935, as compared with $288,055 in 1899.

The acreage occupied by nursery products in Minnesota increased from 1,127 in 1899 to 3,854 in 1909, an increase of 242 per cent. The value of the nursery products in 1909 was $863,014, as compared with $383,105 in 1899.

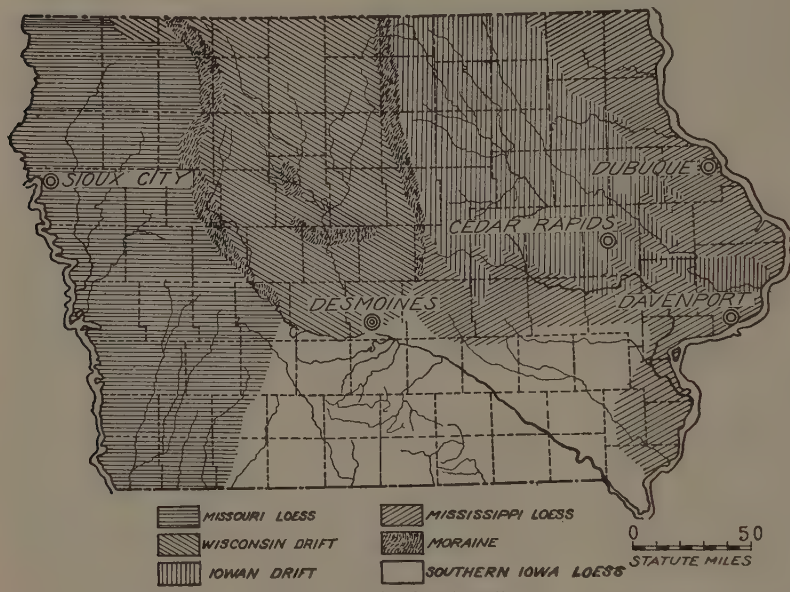
LEROY CADY.

Iowa.

Iowa (Fig. 2502) is nearly a rectangle, about 200 miles north and south between the parallels 40° 36′ and 43° 30′, and 300 miles east and west, bordered on the east by the Mississippi and on the west by the Missouri and Big Sioux rivers. Its extreme elevations are 444 feet in the southeast corner and 1,694 feet at the highest point near the northwest corner, the average elevation being about 800 feet above the sea. The annual rainfall, coming largely from the moist airs of the Gulf, varies with the altitude; in the southeast corner, 37 inches and in the northwest corner, 27.37 inches, at Des Moines, 32.66 inches, which last is nearly the average for the state. The annual temperature is 51° in the southeast, 44° in the northwest and 40° at Des Moines, also about the average of the whole state. The surface is a gently undulating grassy plain, well drained by numerous streams flowing into the rivers at its borders. All these streams are bordered more or less broadly with belts of native timber, often many miles in width along the lower parts of the larger ones. The divide between the streams flowing eastwardly and those flowing westwardly is a line running from a little east of the northwest corner, southwardly to about the middle of the state at the south line, draining three-fourths of the state into the Mississippi and one-fourth westwardly. The entire surface, except a short and narrow belt along the Mississippi at the northeast corner, is deeply covered with glacial drift, the depth varying from a few feet to 200 feet or more. In about half the state this drift is overlaid more or less deeply with a peculiar deposit called loess, this being mainly in the south and extending north on the west side, and in a narrower belt on the east, to the north line of the state. There are no other regions the size of Iowa which contain fewer acres unfit for agriculture; which is as profitable in the northern as in the southern part.

Horticulture is, however, profoundly affected by a region of glacial drift which, coming in from the north, occupies much more than half of the state; embracing that part of Iowa lying north of a line drawn from about latitude 42.5° (Sioux City) on the west, to 41.5° (Des Moines) in the central part, thence to the northeast corner of the state, latitude about 43.5°. In this new drift soil, fruit-growing is much more difficult than in the loess regions above mentioned. During the past few years, however, artificial drainage in this region has been rapidly developed, making it one of the richest agricultural sections in the Union and greatly increasing the range of horticultural possibilities. There, while statistics are still unavailable, are found the greatest development of the americana (native) plums, strawberries, gooseberries and currants, in this state, with splendid home market. Hardy varieties of apples and grapes, hybrid plums, raspberries, and blackberries are being successfully planted, though not yet in sufficient quantity to supply the local demand.

The most favorable regions for the apple are found in the southwest and southeast along the Missouri, Mississippi and Des Moines rivers, where the so-called "bluff deposits" have their greatest development. This is a light-colored, porous soil which endures drought and flood, and is especially friendly to the apple, the cherry, and the grape, and, in fact, all fruits of the region. The leading varieties of apples in the older commercial orchards are Jonathan, Grimes, Ben Davis, Gano, Winesap and Black Twig, probably ranking in value according to the order named. Of late, Delicious, Stayman, and Ingram have been very freely planted in the southern part; while in the north, Wealthy, Malinda, and Northwestern Greening are most prominent. Spraying is generally carried on in the larger centers but clean tillage in the older orchards is rather the exception than the rule.



2502. Iowa, showing the soil areas.

The sour cherry occupies second place in Iowa fruits and promises most rapid development. Especially successful wherever the loess soil is found, it does not reach commercial importance beyond latitude 42.5° (Sioux City and Dubuque) on the west and east of the state, the line of success dropping about 1° of latitude southwardly in the center of the state, where the newer drift has overlaid the loess. By reason of the failure of cherry in the northern half of the state, there is a splendid market, practically inexhaustible, at good margin, for all surplus cherries grown in the southern half. Early Richmond is by far the most valuable, with Montmorency second and English Morello third. Sweet cherries do not succeed.

The plum, while of considerable annual value, is not strictly a commercial fruit of Iowa. Being the native home of a large number of pure americana varieties, this class of course finds its greatest development within the state, especially the northern part. Of these, Terry, De Soto, Wyant, Hawkeye, Wolf and Hammer remain most prominent, with Wild Goose leading the Chickasaw or narrow-leaf type. The many fine hybrid plums promise to bring Iowa forward as one of the principal plum-growing sections of the Middle West.

The culture of the peach, domestica and Japanese plums does not reach north much beyond latitude 41.5°, though it is pushing steadily northward by the adoption of newly introduced seedling varieties. The peach is developing considerable commercial importance in the extreme southern part, while the domestica and Japanese plums are decreasing in favor owing to the lack of hardiness and strong tendency to rot.

Pears, while rather freely planted throughout the loess soil sections of the state, have become commercially prominent only in a few limited areas, notably the bluffs along the river south of Des Moines and near the eastern border from Davenport southward. The largest individual pear orchard at present includes over 100 acres, owned by B. A. Matthews, of Knoxville, largely Kieffer, from which eight to fifteen carloads are shipped annually. Generally, however, the soil is found too heavy for successful pear-culture; only the thin-soiled bluffs and hillsides can be recommended for pear orchards, and these must be seeded down and sometimes root-pruned to prevent disastrous blight.

Practically all parts of the state can produce good grapes, though the centers of commercial vineyards are largely confined to the regions surrounding Council Bluffs on the west and Des Moines in the central part. Concord, Moore Early and Worden comprise fully 90 per cent of the planting, the Concord proving most reliable, Moore Early generally most profitable an acre.

Next to sour cherry and hybrid plums, the most rapid advancement is now being made in the planting of the blackcap raspberries. About fifteen years ago, thousands of acres were devoted to this fruit throughout the south central belt of the state, but low prices, due to an undeveloped market and the general spread of the anthracnose fungus disease, discouraged fruit-growers. Plantations destroyed by the disease were not replanted, causing a decided decrease in raspberry-production. Prices have since been going steadily upward until now with prospect of netting from $200 to $350 an acre annually with favorable seasons and good care, rather extensive planting is again resumed. On account of the excellent outlet to the north for surplus fruit, besides a splendid home market, it is likely that Des Moines will remain the principal raspberry center. Cumberland first, with Gregg a close second, and Kansas for early fruit, constitute the bulk of the planting. Shallow cultivation and summer mulch to protect against drought at harvest time, bring best results.

The fruits which have been and are likely to remain most prominent commercially over the state are the apple, the cherry, grapes, strawberries, and raspberries. Almost without exception, the perishable fruits are grown in greatest volume near the large market centers of the state, the only prominent exception being in the case of cherries and grapes extensively grown for annual shipment to northern and northwestern markets, extending into Minnesota and the Dakotas. The three principal centers of commercial cherry- and grape-culture are: (1) along the Missouri River, on the west, from Sioux City down to the Missouri line; (2) along the Mississippi and some of its Iowa tributaries, from Davenport southward; and (3) in the vicinity of Des

Moines. Small-fruits, figured on the basis of actual consumption and based on an average for the state, will probably exceed in value all the tree-fruits combined, the small-fruits being limited to no particular area but successfully grown for home use and local market in all parts of the state.

The Atlantic seaboard, with its 200 years of seedling orchard production before budding and root-grafting became common practice, was enabled through necessity, by seedling selection, to develop its "apple kings" and other fruits, all specially adapted, by reason of such seedling selection, to the soil and climate of the region. The first surprise and disappointment came to the early settlers of Iowa when they discovered that the fruits, so desirable and profitable in the East, either winter-killed or proved quite barren in this region. The later introduction of pure Russian fruits under the auspices of a misguided state official, proved a complete failure with few exceptions. The shock horticulture received from these two experiences retarded the development of the pomology of the state. The introduction of budding and root-grafting by nurserymen in propagating all fruit-trees terminated compulsory seedling selection. Gradually, as the needs of this great inland prairie region of hot dry summers and fierce changeable winters were realized, enthusiastic and devoted breeders have been at work with the result that Iowa and her sister states are now experiencing a far greater degree of practical pomological development than any other region in the western hemisphere.

The rich soils and abundant rains during the growing season invite the extensive development of market-gardening. The fast-growing cities, the gradual westward trend of manufacturing, and the numerous canneries scattered over the state, offer a splendid and constantly increasing market. Heretofore the first impulse of practically every agriculturist was to devote himself wholly to corn, grain and live-stock, and it has been only in these limited areas where general agriculture could not be pursued with most satisfactory results, that commercial fruit-growing and market-gardening received deserved attention. Gradually, with the steady increase of land values, demanding more intensive farming, and the dissemination of the knowledge that one must conserve and husband the resources of the soil, fruit and vegetables are becoming more generally developed. The best fruit sections of the state are those most prominent in market-gardening because land values are the highest and modern economical methods have proved the need of constant cultivation leading to intercrops of vegetables of highest market values. The most important vegetable is the potato, successfully grown on new land in all parts of the state. Sweet corn is grown in small quantities in all sections to supply abundantly home needs and local markets, while in the vicinity of canning-plants, most numerous in the central and northern part of the state, many thousand acres are devoted to this product. Generally, beans, peas, and tomatoes are also grown rather extensively in the vicinity of the canneries. Onion-, celery- and watermelon-culture are advancing in importance, being rather general over the state in a limited way, though reaching a stage of considerable importance along the eastern border, centralizing in the vicinity of Muscatine along the Mississippi River.

The nursery business has had large development in the state of Iowa. At Shenandoah, near the southwest corner of the state, are two of the largest wholesale nurseries found in the West. Other important nurseries are carried on at Des Moines, Charles City and other places, while small establishments are found in almost every county.

Public-service agencies for horticulture.

The land-grant college in Iowa and the Iowa Experiment Station are located together at Ames and work in close harmony. At present there are eleven men on the horticultural staff of the College engaged in instruction work. The pomology section has one sub-station in connection with a leased orchard at Council Bluffs, where problems in orchard and soil management are especially studied. The number of horticultural bulletins is at present eight, all published within the last ten years.

The State College at Ames is the only school giving special instruction in horticulture. The State Teachers College at Cedar Falls gives horticultural work in connection with agriculture, but no special course in horticulture. At present, horticulture is taught in over 150 high-schools of the state. Beginning with the fall of 1915, similar instruction will be furnished in some 800 schools of the state, in compliance with a law lately enacted.

The State Horticultural Society receives from the state $4,000 annually for its use. It holds its annual meeting in December of each year and prints a report of its own proceedings, as well as of its four subordinate district societies.

The extension work in horticulture is handled through the division of agricultural extension of the Iowa State College. At the present time there are three men on the extension staff in pomology and truck crops. The work of these men is supplemented by the assistance of other members of the college and experiment station staffs and consists of farm institutes, short courses, orchard and garden demonstrations, farm tours, and so on.

The inspection service in Iowa is handled through the office of the State Entomologist and applies strictly only to injurious insects, though the nurserymen, in coöperation with the State Entomologist, have maintained inspection for injurious diseases.

A very important work not connected with state institutions has been conducted by C. G. Patten, assisted by support from the State Horticultural Society, the state and the general government. There are about 20 acres near Charles City thickly planted with cross-bred and selected stock, chiefly of apples, pears, plums and cherries, with more or less of many other kinds of fruits and plants. A number of apples originated at this experiment station have entered into general use in large sections. There has also originated at this station a new race of pears by crossing the Chinese sand pear with American sorts of better flavor. Several generations of trees are growing which are entirely hardy and blight-proof in the extreme north of the state, so that there is promise of plenty of good pears in the near future in the orchards of Iowa.

Statistics (Thirteenth Census).

The approximate land area is 35,575,040 acres. The land in farms is 95.4 per cent of the land area, or 33,930,688 acres. Of the land in farms 86.9 per cent, or 29,491,199 acres, are improved; 2,314,115 acres are in woodland; and 2,125,374 acres are classified as unimproved land in farms. The number of all the farms in the state in 1909 was 217,044, there being 156.3 acres in the average farm. [The area of Iowa is 56,147 square miles.]

The leading agricultural crops are the cereals and hay and forage. In 1909 the acreage devoted to cereals was 15,041,039, or 51 per cent of the improved land. The value of the cereal products for the same year was $230,205,315, which was 73.2 per cent of the total value of all crops. The acreage devoted to hay and forage was 5,046,185 in 1909 and the value of the products $59,360,225, which was 18.9 per cent of the total value of all crops. Sugar crops were raised to the extent of 7,276 acres, the production being valued at $208,283. The value of the forest products of the farms in 1909 was $3,649,032, which was 1.2 per cent of the total value of all crops.

Horticultural crops grown are fruits and nuts, small-fruits, vegetables, including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $4,650,875, as compared with $2,023,730, their value in 1899. The acreage devoted to vegetables, including potatoes and sweet potatoes and yams, was, in 1909, 252,243 and their value $12,021,408, thus making vegetables by far the most important of the horticultural crops grown in Iowa. Small-fruits decreased in acreage from 9,635 in 1899 to 7,211 in 1909, when the value of their products was $966,894. As an industry, the growing of flowers and plants and nursery products was of more importance than that of small-fruits. The value of flowers and plants and nursery products in 1909 was $1,503,305 as compared with $939,499, their value in 1899.

The total production of orchard-fruits in Iowa in 1909 was 7,234,168 bushels, valued at $4,283,873. Apples, the most important of the orchard-fruits, produced 6,746,668 bushels alone, which was more than nine-tenths of the total production. The value of the apples produced in 1909 was $3,550,729. Cherries, the next orchard fruit of importance, produced 260,432 bushels, valued at $455,022. The production of plums and prunes in 1909 was 158,036 bushels, valued at $192,421; that of pears, 44,449 bushels, valued at $58,777; that of peaches and nectarines 23,180 bushels, valued at $24,950. In addition, apricots were produced to the value of $942; quinces to the value of $681; and mulberries, to the value of $351.

The production of grapes for 1909 was 11,708,336 pounds, valued at $330,078. The number of grapevines of bearing age in 1910 was 1,983,465; those not of bearing age, 446,126.

The production of nuts in 1909 was 1,721,265 pounds, valued at $36,922. Most of the nuts were black walnuts and hickory-nuts. In 1909 the black walnuts produced 1,134,061 pounds, valued at $20,589, and the hickory-nuts, 539,203 pounds, valued at $15,251. Butternuts were produced to the amount of 37,931 pounds, valued at $758.

Strawberries are by far the most important of the small-fruits grown in Iowa, with blackberries and dewberries, and raspberries and loganberries ranking next. The acreage devoted to strawberries increased from 2,335 in 1899 to 2,917 in 1909, when the production was 5,330,105 quarts, valued at $479,511. The acreage of blackberries and dewberries increased during the same period from 1,719 in 1899 to 2,279 in 1909 when the production was 2,733,728 quarts, valued at $247,734. Raspberries and loganberries decreased in acreage from 3,394 in 1899 to 1,573 in 1909. In 1909 the production was 1,728,547 quarts, valued at $191,037. The same year the production of currants was 317,637 quarts, valued at $27,315; and that of gooseberries 233,544 quarts, valued at $21,251.

Of the vegetables, the potato is by far the most important. In 1909, 169,567 acres devoted to potatoes produced 14,710,247 bushels, valued at $6,629,234, more than half the value of all vegetables produced. Among the leading vegetables, other than potatoes, their acreage, and the value of the products were: sweet corn, 12,568 acres, valued at $219,220; cabbage, 2,789 acres, valued at $148,529; pop-corn, 5,345 acres, valued at $135,270; sweet potatoes and yams, 2,274 acres, valued at $125,763; onions, 849 acres, valued at $118,155; watermelons, 3,464 acres, valued at $112,217; and tomatoes, 2,055 acres, valued at $100,457. Other vegetables grown in Iowa in 1909 were asparagus, green beans, cantaloupes and muskmelons, celery, cucumbers, lettuce, green peas, radishes, and turnips.

The acreage devoted to the production of flowers and plants increased from 140 in 1899 to 361 in 1909, an increase of 157.9 per cent. The total area under glass in 1909 was 2,183,182 square feet, of which 1,870,845 were covered by greenhouses and 312,337 by sashes and frames. The value of the flowers and plants produced in 1909 was $657,393, as compared with $320,407, their value in 1899.

The acreage occupied by establishments producing nursery products was 3,430 in 1909, as compared with 2,905, the acreage in 1899, an increase of 18.1 per cent. The value of the nursery products in 1909 was $845,912, as compared with $619,092, the value in 1899.

C. L. Watrous.

Missouri.

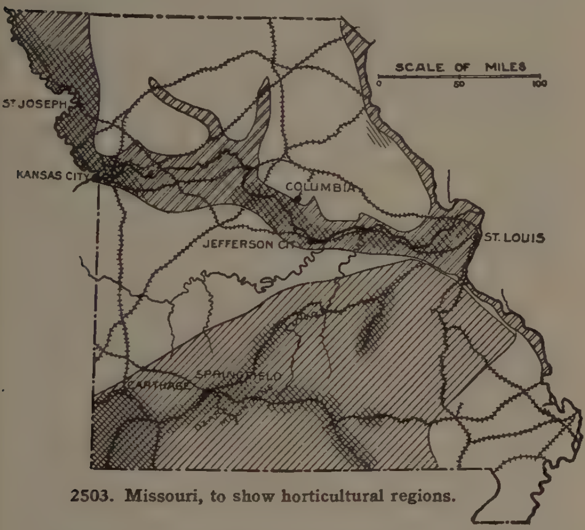
Its central position gives Missouri (Fig. 2503) a medium climate, favorable to the growth of a variety of horticultural products. The cosmopolitan character of its plants is indicated by the native flora. Northern, southern, eastern and western species blend and overlap here. The wild crab of the prairie states and the juneberries, capable of enduring the rigors of a northern winter, flourish here in the same forest with the more southern persimmon and the pawpaw. The northern grapes of the Labrusca type, like Concord, are among the standard varieties, while on the other hand tender varieties like Herbemont and the tender hybrids usually winter safely. The riparia group is native to the state, while the more tender *Vitis rotundifolia* of the Gulf region reaches splendid natural development in the southeastern part of the state. While the berries and small-fruits common to the northern states endure well the warmer climate of Missouri, the oriental persimmon, English walnut and *Poncirus* (*Citrus*) *trifoliata* are hardy in the southern part. The northern plum (*Prunus americana*) extends south into Missouri where it mingles in the same woodlands with the southern Chickasaw plum (*P. angustifolia*). These two have hybridized in nature, and some of these hybrids have found an important place in our list of cultivated American plums.

Missouri's central position is also favorable to the marketing of her fruit. Perishable fruits, such as berries and peaches, are shipped to nearly all of the principal markets east of the Rocky Mountains, from Boston and Baltimore on the east, Omaha, Denver and Pueblo on the west, and from St. Paul and Detroit on the north to Mobile, New Orleans and Galveston on the south. Some of the grain-raising, mining and grazing states of the west and northwest, where but little fruit is produced, furnish a growing market for Missouri fruit. The Mississippi and Missouri rivers, with their tributaries, touching the entire length and breadth of the state, furnish cheap freight rates north, south, and northwest, and direct railroad connections with the Gulf ports afford cheap shipment of apples to European markets.

The following figures give the average monthly rainfall in inches as recorded at Columbia by the United States Weather Bureau: January, 1.89; February, 2.57; March, 2.97; April, 4.52; May, 5.87; June, 4.56; July, 4.85; August, 2.81; September, 3.60; October, 1.40; November, 2.87 and December, 2.02. While these figures show the rainfall is ample (approximately 40 inches annually) and well distributed throughout the year, the records also show the percentage of sunny days in this immediate section is high. During August, September and October, especially, when most of the fruit is maturing, the average amount of bright sunlight is considerably higher than that of most of the orchard states. No doubt the intense sunlight and the proximity to the prairies are important factors in producing the rich color and high flavor of Missouri fruit, and may also account, in part at least, for its comparative freedom from many of the fungous diseases which are known to thrive best in a moist cloudy atmosphere.

The topography and soil of the state are both favorable to fruit-growing. The undulating areas, intersected by the Mississippi and Missouri rivers and their tributaries, are amply provided with both soil and atmospheric drainage. The more important fruit-soils include the deep, rich, loess formation (see Fig. 2503) forming the hills and tablelands overlooking the two great rivers of the state. Wherever this loess occurs, the world over, it is recognized as a typical fruit soil. The light, deep, brownish red clay loam of the Ozark uplift, containing sufficient sand and broken rock to afford excellent drainage, is also an important fruit-soil. The extensive swamp region in the southeastern part of the state is now being drained by the dredging of an extensive ditch system and is bringing under cultivation a large area of the very richest soil. This is becoming one of the most important vegetable-producing sections of the state. The growing of watermelons especially has already reached important development. Blodgett is said to be the largest watermelon shipping point in the United States. The higher second bottom-lands of the two great river-systems are also splendidly adapted to the production of orchards and of truck-crops.

The census for 1900 credited Missouri with over 20,000,000 apple trees in her orchards. This was 33⅓ per cent more than were reported for any other state. Something over 8,000,000 were reported in 1890, showing an increase of over 12,000,000 apples trees in a single decade. This was a larger number of apple trees planted in a single decade in Missouri than were growing in the year 1900 in any other states, except three. This enormous activity in apple-orchard development resulted in putting out some of the largest orchards in the world. Some of the Missouri orchards contain upward of 2,000 acres, a considerable number are of more than 1,000 acres in extent, and orchards of several hundred acres each are quite usual in almost any of the orchard districts of Missouri. This enormous planting in so short a period and largely in newly developed regions has resulted in some of the plantings going out on soil which has since proved to be unadapted to the industry. Many of the larger orchards put out in newly developed regions where insects and diseases had not had opportunity to get a foothold produced profitable crops early, but are too large to receive the care necessary to protect them from insects and fungous diseases which follow closely upon the march of orchard development. For that reason, some of the larger orchards of the state have perhaps not been so profitable as was expected. On the other hand, this extensive pioneer work in orcharding has been the means of shaping profitable orcharding of today. It has helped to map the successful orchard areas in contrast to those soils less adapted to the industry. It has shown the adaptation of varieties to the state and the local adaptation of special varieties to the various districts within the state. As a result, the conservative orchardist of today is profiting by the experience of the pioneers whose extensive efforts gave to the state the sobriquet of "The Land of the Big Red Apple."



2503. Missouri, to show horticultural regions.

The present status of orcharding in the state rests upon a sound commercial basis. The grower knows the adaptability of the different soil formations and of the various varieties. The present trend is toward the planting of moderate-sized orchards to the varieties which have been proved to be most profitable for the neighborhood, and to the adoption of modern methods of pruning, spraying, packing and marketing of fruit, which is resulting in substantial profit.

The state has a large and growing nursery interest. The loess soil along the two great rivers and the richer soils of the Ozark region produce especially fine nursery stock. At Louisiana is located one of the pioneer nurseries of the Mississippi Valley, which is now said to be the largest nursery enterprise in the world.

The Ozark section and river hills produce exceptionally fine yields and quality of tomatoes for canning purposes. Canning factories prosper in various parts of the state, the tomato being the leading product canned.

The southwest section of the state is a notable strawberry-producing region; Sarcoxie, Pierce City, Monett and other towns adjacent are leading strawberry shipping points. Some of these towns ship several hundred carloads annually.

About Canton, St. Joseph, and other points, extensive pickle-producing interests have developed. The production of cucumbers and other pickle-producing plants is becoming a growing industry. In the northwestern section of the state large quantities of cucumbers are grown for seed. About St. Louis and vicinity, the production of horse-radish is extensively developed. In St. Louis and Carroll counties, the production of early potatoes for July shipment has reached a prosperous development, and early potato-growing is rapidly taking its place in the agriculture of the state.

The floriculture interests of the state are large and increasing. St. Louis and Kansas City have extensive greenhouse enterprises, not only for local market, but for shipment. At Lee's Summit is one of the largest greenhouse plants in the country. Even in some of the smaller cities, the production of flowers under glass is in many cases more than supplying the local demand. Roses, carnations, violets, bulbous plants, and bedding plants are the leading crops, but many firms do a very general business in plant-production. The region is especially favorable for winter greenhouse work. The proportion of sunny days is unusually high as compared with other sections of the country in which floriculture has reached important proportions. Winter temperatures are not severe. The light snow and comparative freedom from ice obviates the difficulty experienced in many other sections.

Along the Missouri River hills are developed in the loess soil formation numerous grape- and wine-producing centers. Herman particularly possesses very extensive wine-cellars.

Within the past fifty years a notable number of varieties of fruit have originated within the borders of the state. It is interesting to note that while up to thirty years ago the varieties recommended by the state were mostly of Atlantic coast or European origin, the present list of commercial varieties very largely originated either in Missouri or adjacent territory. Some of these have been distinct additions in the way of local adaptation—for instance, the Ingram apple originated at Springfield, is the latest-blooming sort grown commercially in the state, escaping late spring frosts, and is perhaps the most important commercial variety for the southern and western slopes of the Ozarks. The amelioration of our native species of grapes has taken the attention of many prominent Missouri horticulturists. In this connection should be mentioned the work of Engelmann in the classification of the grape and the work in grape-breeding by Judge Miller, Jacob Rommel, Herman Jaeger and many others, including the contributions of Dr. Stayman, whose initial work began in Missouri. This state will be remembered as the home of the Soulard crab, and seedlings of this hybrid are now being grown which promise to bring its stock to an important place in our cultivated varieties.

While horticulture is already one of the leading interests of Missouri, the possibilities of the state in that direction have not yet been even approximated. While many of our pioneer orchards were located on soils and sites not well adapted to fruit, still only a small proportion of the soil which has been proved beyond a doubt to be splendidly adapted to profitable orcharding and berry-growing has as yet been cultivated. In recent years, however, steps in advance are rapidly being taken. The best growers are planting varieties of the finer types of dessert fruit, instead of clinging to the commercial varieties of mediocre quality which first made the state famous as an apple section. For the most part, men who are making money out of their orchards and fruit plantations today are those with smaller areas well cared for and whose enterprise has not come to notice outside the state. New varieties better adapted to local conditions are being originated. Our native fruits and nuts are receiving attention and improved varieties of these are already the result. One of the problems confronting the early orchardist was the fact of our comparatively mild but changeable winters. Northern varieties were often forced into early bloom before danger of spring frosts was over. Varieties like the Ingram apple mentioned above are now being introduced which possess a more persistent rest period and escape spring frosts. The horticulture of the state is rapidly rounding into a stable condition and bids fair to reach very important proportions.

Public-service agencies for horticulture.

The College of Agriculture was established in 1870, as a department of the State University at Columbia. Of the agricultural college staff five members devote their time to giving instruction in horticulture. In addition two or three special assistants, usually advanced students, are employed during the summer to conduct orchard demonstrations in spraying, pruning, harvesting, packing, and so on, in the various fruit-growing districts of the state.

The Experiment Station is also located at Columbia as a department of the State University. Four members of its staff devote their time to horticultural problems. Between forty-five and fifty horticultural bulletins have been published, giving the results of investigation work to date (1915). In addition a large number of circulars and press bulletins have been sent out.

The Missouri Fruit Experiment Station is located at Mountain Grove. It was established by legislative enactment in 1899. The working staff consists of a director and horticulturist, a pathologist and an entomologist. This institution is rendering splendid service to the horticultural interests of the state by conducting demonstration work in spraying, pruning and other phases of orchard-management in the fruit centers and also through investigation work which is being done at the station.

The Missouri Botanical Garden, located in St. Louis and richly endowed by the will of the late Henry Shaw, maintains a school for training students in horticulture. Five state normal schools, located at Cape Girardeau, Kirksville, Maryville, Springfield and Warrensburg respectively, give teachers courses in agriculture and horticulture. Lincoln Institute, a state school for negroes, located at Jefferson City, gives instruction in agriculture and horticulture.

The State Department of Education and the public schools early took a leading part in introducing the study of agriculture and of horticulture. The teaching of agriculture and horticulture is required in all the rural schools of the state. Legislative enactment provides state aid for high-schools which maintain specified equipment, grounds and courses of study in agriculture and horticulture. At present (1915) there are about 450 high-schools in the state which are fulfilling this requirement for state aid.

The Missouri State Horticultural Society, established in 1859, has held annual meetings for a period of more than fifty years. Fruit exhibits as well as papers and addresses by leading horticultural talent are a feature of these meetings.

The State Board of Horticulture was established by the state legislature in 1907 to promote the interests of fruit-growing in Missouri. In 1913 the Board published a census of all the commercial orchards of the state.

Several of the above agencies conduct extension work in horticulture. The Missouri Fruit Experiment Station conducts practical demonstrations. The department of horticulture at the State University gives extension instruction in horticulture through extension short courses. In coöperation with the county superintendents of schools, the University conducts boys' and girls' contests in such work as tomato-growing and potato-growing.

Statistics (*Thirteenth Census*).

The approximate land area in 1910 was 43,985,280 acres. The land in farms was 34,591,248 acres, or 78.6 per cent of the land area. Of the land in farms 24,581,186 acres were improved; 8,918,972 acres were in woodland; and 1,091,090 acres was other unimproved land in farms. The total number of farms in 1910 was 277,244. The average acreage a farm was 124.8. [The total area of Missouri is 69,420 square miles.]

The leading agricultural crops of Missouri are cereals, hay and forage, with cotton and sugar crops secondary in importance. The acreage of cereals was 10,423,745 in 1899 and 10,255,476 in 1909, when the value of the products was $147,980,414, which was 67.1 per cent of the total value of all crops. Hay and forage increased in acreage from 3,481,506 in 1899 to 3,628,348 in 1909, when the value of the products was $33,845,094. Cotton increased in acreage from 45,596 in 1899 to 96,527 in 1909, an increase of 111.7 per cent, when the value of the production was $3,978,295. Sugar crops increased in acreage from 30,997 in 1899 to 45,268 in 1909, when the production was valued at $1,039,168. The value of the forest products of farms was $8,406,823 in 1909, as compared with $4,442,131, their value in 1899.

Horticultural crops grown in Missouri are fruits and nuts, small-fruits, vegetables including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $7,111,279, as compared with $3,278,840 in 1899. The acreage of small-fruits increased from 14,860 in 1899 to 17,009 in 1909, when the production was 23,696,221 quarts, valued at $1,761,409. In 1909, the total acreage of potatoes and other vegetables was 233,767 and their value $13,305,829. Excluding potatoes and sweet potatoes and yams, the acreage of vegetables was 129,570, and their value $8,268,281, the acreage and value being an increase of 11.5 per cent and 49.1 per cent, respectively, over the acreage and value in 1899. The acreage devoted to flowers and plants and nursery products decreased from 3,152 in 1899 to 2,842 in 1909, when the value of the products was $1,183,297.

The total production of orchard fruits in 1909 was 11,957,339 bushels, valued at $6,582,578. Apples contributed about five-sixths of this production, and peaches and nectarines most of the remainder, the production of apples being 9,968,977 bushels, valued at $4,885,514; and that of peaches and nectarines 1,484,548 bushels, valued at $1,110,550. The number of apple trees of bearing age in 1910 was 14,359,673; those not of bearing age 3,624,833; peach and nectarine trees of bearing age in 1910 numbered 6,588,034; those not of bearing age, 1,404,429. Other orchard-fruits produced in 1909 were: 123,314 bushels of cherries, valued at $222,510; 142,547 bushels of pears, valued at $148,789; 234,872 bushels of plums and prunes, valued at $211,472; and minor quantities of apricots, quinces, and mulberries.

In 1909, 17,871,816 pounds of grapes were produced, valued at $488,755. The grape-vines of bearing age in 1910 numbered 3,026,526; those not of bearing age 486,044.

The total production of nuts in 1909 was 2,823,368 pounds, valued at $39,746. The greater quantity of these were produced by black walnuts, the production in 1909 being 2,446,402 pounds, valued at $24,526. Pecans, next in importance, produced 147,420 pounds, valued at $10,467; hickory-nuts produced 210,228 pounds, valued at $3,633; and Persian or English walnuts, 5,791 pounds, valued at $618.

Strawberries are by far the most important of the small-fruits grown in Missouri, with blackberries and dewberries second in importance. The acreage of strawberries increased from 7,498 in 1899 to 9,048 in 1909, when the production was 15,171,034 quarts, valued at $1,122,784. The acreage of blackberries and dewberries increased from 4,441 acres in 1899 to 5,975 in 1909, when the production was 6,391,209 quarts, valued at $456,283. The production of raspberries and loganberries was 1,563,527 quarts, valued at $133,196; that of gooseberries, 470,029 quarts, valued at $39,941; that of currants, 91,207 quarts, valued at $8,312; and that of cranberries, 6,944 quarts, valued at $618.

The acreage devoted to the growing of potatoes in Missouri increased from 93,915 in 1899 to 96,259 in 1909, when the production was 7,796,410 bushels, valued at $4,470,135. The acreage devoted to the sweet potato and yam was 7,938, in 1909, a decrease of 19.4 per cent from the acreage in 1899. The production in 1909 was 876,234 bushels, valued at $567,413. The more important of the other vegetables were: 11,083 acres of tomatoes, valued at $322,426; 10,727 acres of watermelons, valued at $258,940; 2,858 acres of sweet corn, valued at $80,928; 959 acres of cabbage, valued at $79,707; 1,701 acres of cantaloupes and muskmelons, valued at $65,380; and 374 acres of horse-radish, valued at $62,694. Vegetables of minor importance produced in 1909 were asparagus, green beans, beets, cauliflower, celery, popcorn, cucumbers, lettuce, onions, green peas, green peppers, radishes, rhubarb and turnips.

The acreage devoted to the production of flowers and plants increased from 181 in 1899 to 383 in 1909, an increase of 111.6 per cent. The total area under glass was, in 1909, 2,812,221 square feet, of which 2,545,138 were covered by greenhouses and 267,083 by sashes and frames. The value of the flowers and plants produced in 1909 was $653,903.

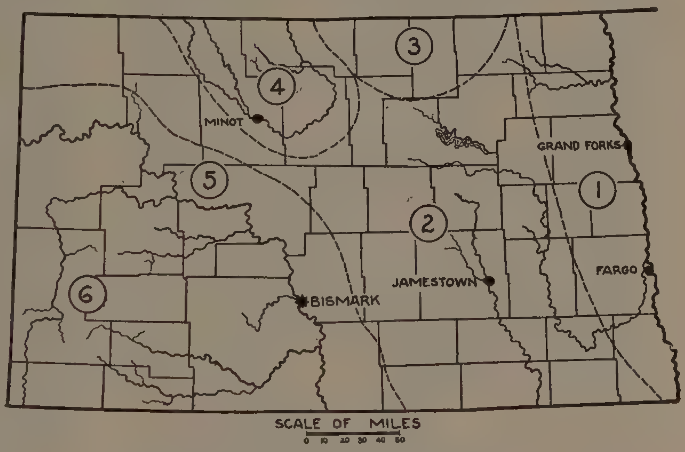
The acreage devoted to nursery products, however, decreased from 2,971 in 1899 to 2,459 in 1909, when the value of the products was $529,394, as compared with $349,449 in 1899.

J. C. Whitten.

North Dakota.

North Dakota (Fig. 2504) lies between latitude 46° and 49° north, and longitude 96° 25′ and 104° west. The special advantages of soil and climate for the production of grass and the small grains have given the state great agricultural prominence, but little has been done along horticultural lines. While it possesses undoubted possibilities along certain lines of fruit-production, and in the growing of certain vegetables can hardly be excelled, yet these things have always been considered incidental and not to be classed with the leading soil industries. North Dakota settlers, for the most part, did not come from fruit regions, and in no case have they occupied the land with other intention than to raise stock and grain. At the same time, as population increases and homes become established, there is the natural tendency to protect these homes with trees, ornament them with shrubs and flowers, and furnish the table with vegetables and fruit.

The distinctive regions of North Dakota are referred to as Red River Valley (Section 1), the Turtle Mountain country (3), the Devil's Lake region (2), the Mouse River country (4), the James River Valley (2), the Missouri slope (5) and the western range country (6), including the Bad Lands. The Red River Valley is a level plain from 20 to 30 miles wide on the North Dakota side and extending across the state north and south, thus embracing an uninterrupted area of some 6,000 square miles, all level and of great fertility. This is preëminently the wheat-belt of the state, and the character of the soil is such in both physical and chemical properties as to insure an excellent growth of such plants as are hardy and will mature within the season. The soil is a lacustrine deposit containing about 33 per cent of very fine sand, 55 per cent clay and silt, and 12 per cent organic matter and soluble salts. It is so rich in nitrogen and phosphoric acid as to be quite indifferent to fertilizers, even when applied to such garden vegetables as demand the most fertile soils. It rarely bakes under reasonable cultivation, is never lumpy and is very retentive of moisture. It is unusually well adapted to the cultivation of practically all vegetables, particularly celery and other plants requiring a deep, fine, easily worked soil.



2504. North Dakota, with the six areas.

This general type of soil is not confined to the Red River Valley, but is the predominating surface soil for most of the state lying east of meridian 101 and of considerable tracts still farther west. The subsoil in the Red River Valley lying under 3 or 4 feet of very dark loam is uniformly a soft yellowish clay extending to a great depth. Much of the subsoil outside of the valley is largely made up of firmly compacted sand, with a small percentage of clay. Such lands are not so good as those having the clay subsoil, but with the good surface soil which they support they are capable of producing large yields in seasons not too dry. They ar naturally not so well adapted to horticultural operations as are the lands having the clay subsoil.

Speaking in general, the soil lying west of the 100th parallel, also that of the Missouri slope, Turtle Mountain and Mouse River counties is all well suited to vegetable- and fruit-culture, though partial failure may result from short seasons. This is especially true upon the level, rich soil of the Red River Valley, which tends to prolong the growth of such plants as the grape and apple beyond the season in which they should mature. The more rolling surface of the land along the Missouri River affords opportunity to select favorable sites for fruit plantations, and there is doubtless some advantage in the soil itself. This is apparent in the cultivation of the grape, or such vegetables as the tomato, squash and melon. So far, attempts to grow fruit on the lighter and more rolling soils, avoiding the extremes, has met with reasonable success. On the heavier soils and level lands, success has been confined to the cultivation of such small-fruits as the currant, gooseberry, raspberry and American plum, and vegetables maturing not later than the earliest sorts of tomato or second-early sweet corn. In connection with the fact that attempts at apple-culture have generally been unsuccessful, it should be remembered that plants, as a rule, cannot make long jumps. The line of apple-culture is gradually moving northwest, the successful varieties being those, like the Wealthy and Patten Greening, that have originated in the newer places. A region so far removed from the apple districts as North Dakota must have time and opportunity to develop varieties of its own.

Removed from all influence of large bodies of water, North Dakota has a comparatively dry climate subject to considerable extremes of temperature. The mean annual rainfall at Fargo for the years 1892 to 1909 was 21.25 inches, distributed by seasons nearly as follows: spring, 6 inches; summer, 10.5 inches; fall, 3.75 inches; winter 1 inch. Most of the precipitation is in spring and summer, when it is most needed. The average rainfall for June is 4.17 inches. The fact that the larger part of agricultural lands in the state are absolutely flat, as near as land may be, and composed of a soil very retentive of moisture, makes what would otherwise be a light rainfall generally sufficient for ordinary needs. Farther west than Fargo, the rainfall gradually becomes less.

The temperature is very uniform throughout the state, with the general difference that the range country in the western part has milder and more open winters, and the higher altitude, as well as latitude, of the northern tier of counties gives them a shorter and cooler summer, more inclined to frosts. It is only in that section that corn has not been considered, so far, as a possible crop.

The winters are cold but dry and agreeable. An occasional winter with too much sunshine kills young trees of the thin-barked varieties through the process of desiccation. The springs are short, the warm days of summer coming very soon after winter and some time before the frost is out of the ground. In summer the days are long and sunny, with nights invariably cool. This condition gives the most perfect development of hardy vegetables, like the cabbage and celery, but retards the cucurbits and other semi-tropical species.

General settlement of what is now North Dakota did not begin till the building of the first railroad in 1873, and any effort to grow fruit has been made since that time. In 1874, Andrew McHench, of Fargo, made the first attempt at fruit-growing upon any extended scale. In that year he bought at a nursery in Minneapolis a carload of young apple and crab-apple trees of such varieties as the Wealthy, Hyslop and Transcendent, and the year following planted 7,500 root-grafts of these and other varieties. Though he obtained some fruit and at different times grew trees that were models of thrift and fruitfulness, yet the venture was not a success. The varieties that successfully resisted the cold winters succumbed to the blight shortly after they came into bearing. Other attempts by different men made along the Red River Valley since then have resulted similarly. In more recent years, with the elimination of the Transcendent which is especially subject to blight, efforts at apple-growing have been more successful. This has been especially true in the regions of the lighter soils in the southern part of the state. At Cogswell, Hankinson, Lisbon, and Edgeley, there are good bearing orchards of such varieties as the Hibernal, Duchess, Wealthy, Patten's Greening and Iowa Beauty. Any of the crabs are successfully grown, eliminating only those subject to blight. In many other parts of the state, younger orchards are coming on that promise as well as those already mentioned.

The only other tree-fruit hardy in North Dakota is the native plum (*Prunus americana*) and some of its hybrids. Of the pure species there are many varieties that are productive and suitable for home use and local markets but too soft for shipping. The De Soto, Surprise, Weaver, Wolf and Hawkeye, are among the varieties more commonly grown. The hybrids resulting from crosses between the American plum and the sand cherry and also between the American plum and the Japanese plum are all hardy and productive in North Dakota and many of them promise to be of value commercially as well as for home use.

Most commercial varieties of grapes find the seasons too short or the winters too cold, though the Moore Early can be grown in the southern part of the state. The Beta grape is being successfully grown in many parts of the state.

Currants and gooseberries find a congenial soil and climate in all parts of the state and the hardier varieties of raspberries do well when planted near a windbreak so that they will remain covered with snow.

Early attempts at strawberry-growing, before the days of windbreaks, were not very successful. As shelter has been provided and more vigorous varieties have been introduced, the strawberry is being commonly grown for home use. The introduction of the Senator Dunlap was the beginning of successful strawberry-growing in North Dakota.

There are but few vegetables that cannot be produced abundantly and cheaply. This is particularly true of celery, onions, parsnips, and the like, that require a deep, mellow soil. The earlier sorts of sweet corn and tomatoes can be successfully grown in most sections of the state. At the Experiment Station at Fargo, a yield of 1,000 bushels of ripe tomatoes has been secured in some seasons on 1 acre. The ease with which the soil is worked and the fact that no fertilizer is required reduces the cost of production to a minimum.

The horticultural progress of the state since 1900 has been due largely to the development of the nursery industry. This in the early settlement of the state consisted simply of the collection and sale of young seedling trees. These were gathered in great numbers from along the bed of the Missouri River, whose soft banks, always flooded in the spring, especially favored the germination of tree seeds. The cottonwood was the one most usually selected, although the box elder and ash were gathered to some extent. Most of the older groves in the state are from these Missouri River seedlings, the total number planted running into the millions. The supply of forest trees, as well as other nursery stock, is now furnished by the nurseries, of which there are four of considerable size and a number of smaller ones of more recent origin. One of these has devoted its attention largely to the growing of conifers and as a result has a fine stock of many thousands of such hardy species as the jack pine, western yellow pine, Douglas spruce, Black Hills spruce and Colorado blue spruce. At the present time, nursery sales consi chiefly of rapidly growing trees for shelter and windbreak purposes. The common white willow and its variety, the golden Russian willow, the laurel-leaf willow and a variety of the cottonwood, commercially known as Norway poplar, are the trees in greatest demand. The native ash and the box elder are also bought freely. The trade in fruit-trees and ornamentals is considerably less and is still largely furnished by outside nurseries. However, some of the local nurseries have blocks of hardy varieties of apples and plums running into thousands with business increasing rapidly.

Within the past ten years a few floral establishments have been built up in the larger towns and in all cases have met with marked commercial success. While none of them has over 50,000 square feet under glass, yet with the quality of stock produced and the high prices readily obtained the business is decidedly profitable. The growers claim a certain advantage in the bright, clear weather of autumn that gives them carnations and chrysanthemums of unsurpassed color and quality. The same applies to roses, except during December and January, when the short days do not furnish enough hours of daylight for the best results.

While the wild fruits occupy an inconsiderable part of the total area of the state, yet they are important in that they furnish thousands of families with their yearly supply of jellies and other fruit products. A list of the wild fruits in order of their importance would be about as follows: plum, buffalo berry (*Shepherdia argentea*), cherry (*Prunus demissa*), grape (*Vitis vulpina*) and juneberry (*Amelanchier alnifolia*). The red raspberry and strawberry are also found sparingly. The only plum in the state is *Prunus americana*, and this is found wherever other trees or shrubs grow. It is strongly variable in almost every character except fruitfulness, all forms being decidedly prolific. The fruit generally is of good quality, sweet and rich when ripe, but too soft to keep well. In a domestic way, wild plum jelly is recognized as a staple article of superior merit, and though the plums are abundant in most seasons, yet they readily bring $2 a bushel in the local markets. The improved strains of this plum, like the DeSoto, Weaver and Surprise, are being introduced and successfully cultivated. The buffalo berry is found from the James River westward, growing in thickets along streams and coulees. The bright red acid fruit is borne in the greatest profusion, but is rather difficult to gather, as it is sessile and thorns are plenty. It makes a clear jelly of reddish amber-color and delicate flavor. *Prunus pumila* is widely scattered but not abundant, and the fruit is used but little. In the western part of the state the juneberry produces abundantly a large fruit of rich flavor, but is more often used fresh from the bushes than in a culinary way. The rapid settling of the state has increased the demand for native fruits to such an extent that their value is being appreciated, and private ownership even in wild fruits is being insisted upon and recognized. This, of course, leads directly to the development and preservation of the better strains.

Among those influential in developing fruit-growing in North Dakota were Andrew McHench of Fargo and Col. R. H. Hankinson, of Hankinson.

Public-service agencies for horticulture.

The land-grant college of North Dakota was established at Fargo in 1890. There are three members of the horticultural staff.

The Experiment Station is also located at Fargo. There are two horticulturists on the staff. Several regular bulletins and also press bulletins have been issued on horticultural subjects. Within the last twelve years, there have been established from time to time five sub-experiment stations in the different parts of the state, where trials are being made to a limited extent with trees and fruits. At most of these stations, more or less encouraging results with both tree- and small-fruits have been obtained, and in some cases the yield has been such as to indicate commercial success, particularly with the Patten Greening apple and some of the varieties of the American plum.

In addition to these state experiment stations, there was established at Mandan, in 1912, a federal station known as the Northern Great Plains Experiment Station. One of the prominent objects of this station is to carry on trials with horticultural plants of all classes, and to develop fruits suited to the Great Plains region.

There are two special schools in the state teaching horticulture, the School of Forestry at Bottinean and the State Normal School at Valley City. Two terms of horticulture are also taught in most of the high schools.

The nursery inspection is conducted by the state.

Statistics (Thirteenth Census).

The approximate land area of North Dakota is 44,917,120 acres. The land in farms in 1910 was 63.3 per cent of the land area or 28,426,650 acres. Of this land in farms, the improved land numbered 20,445,092 acres; the woodland, 421,877 acres; and other unimproved land in farms 7,549,681 acres. The total number of farms of the state in 1910 was 74,360 and the average acreage to the farm was 382.3. [The total area of the state is 70,837 square miles.]

The leading agricultural crops produced in the state are cereals, flaxseed, and hay and forage. The acreage of cereals increased from 5,610,374 in 1899 to 11,887,141 in 1909, when the production was valued at $149,133,451, which was 82.6 per cent of the total value of all crops. Flaxseed increased in acreage from 773,999 in 1899 to 1,068,049 in 1909, when the production was 10,245,684 bushels, valued at $15,488,016. Hay and forage increased in acreage from 1,410,534 in 1899 to 2,864,218 in 1909, when the production was valued at $12,368,014. The forest products of the farms in 1909 were valued at $235,386, as compared with $112,807, in 1899.

Horticultural crops grown in North Dakota are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $9,702, as compared with $1,177 in 1899. Small-fruits increased in acreage from 67 in 1899 to 399 in 1909, when the production was 285,696 quarts, valued at $39,641. In 1909 the total acreage of potatoes and other vegetables was 67,450 and their value $3,148,304. Excluding potatoes, the acreage of other vegetables increased from 4,289 in 1899 to 13,383 in 1909, when the production was valued at $1,069,125. Flowers and plants and nursery products increased in acreage from 133 in 1899 to 476 in 1909, when the products were valued at $78,218.

The total quantity of orchard fruits produced in 1909 was 5,685 bushels, valued at $9,688, while that of grapes and nuts was entirely insignificant. The apple trees of bearing age in 1910 numbered 15,941; those not of bearing age 70,023, and the production in 1909 was 4,374 bushels, valued at $7,270. The plum and prune trees of bearing age in 1910 were 19,147; those not of bearing age 35,459, and the production in 1909 was 1,048 bushels, valued at $1,866. The cherry trees of bearing age in 1910 numbered 5,076; those not of bearing age, 21,484. The production in 1909 was 209 bushels, valued at $445. The production of peaches and nectarines, pears, apricots, and quinces was insignificant.

Currants are the most important of the small-fruits raised in North Dakota. The acreage of currants increased from 36 in 1899 to 138 in 1909, when the production was 97,598 quarts, valued at $12,128. Strawberries increased in acreage from 3 in 1899 to 88 in 1909, when the production was 66,028 quarts, valued at $10,445. Raspberries and loganberries increased in acreage from 12 in 1899 to 85 in 1909, when the production was 60,742 quarts, valued at $9,141. Gooseberries increased in acreage from 10 in 1899 to 86 in 1909, when the production was 56,804 quarts, valued at $7,332. Other small-fruits produced in 1909 were 3,404 quarts of blackberries and dewberries, valued at $470, and 1,120 quarts of cranberries, valued at $125.

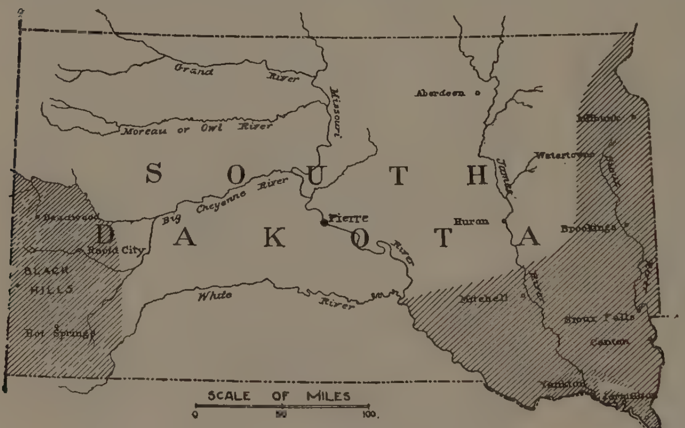
The acreage devoted to potatoes increased from 21,936 in 1899 to 54,067 in 1909, when the production was 5,551,430 bushels, valued at $2,079,125. The more important of the other vegetables produced were: 37 acres of onions, valued at $9,188; 109 acres of cabbage, valued at $8,724; 96 acres of watermelons, valued at $3,719; 141 acres of sweet corn, valued at $3,369; 88 acres of turnips, valued at $3,145; and 7 acres of celery, valued at $1,680. Vegetables of lesser importance, produced in 1909, were asparagus, green beans, carrots, cucumbers, green peas, and tomatoes.

There were 4 acres devoted to the production of flowers and plants in 1909 and the products valued at $47,221. The total area under glass in 1909 was 70,670 square feet, of which 48,150 were covered by greenhouses and 22,520 by sashes and frames. The area devoted to nursery products in North Dakota increased from 131 acres in 1899 to 472 in 1909, when the products were valued at $30,997.

C. B. Waldron.

South Dakota.

South Dakota (Fig. 2505) lies a little north of the center of the continent, between latitude 45° 57′ north, and 42° 28′ south and longitude 96° 26′ and 104° 3′ west of Greenwich. Its shape is approximately a rectangle. Its extreme length from east to west is 386 miles; extreme breadth north to south 240 miles; population (in 1910) 583,888. The Missouri River divides the state into two nearly equal portions. With the exception of a small area in the northeast corner, the southeast part is lowest and all the streams flow in that direction. The state may be divided into three sections: (1) the Black Hills; (2) the Tablelands; (3) the Eastern Section. The Black Hills in the southwestern part are outliers of the Rocky Mountains, and the extensive and very rich deposits of gold, silver, and other minerals are important sources of wealth. The Indians early knew of these gold deposits, but they were not known to white men until 1874. The Black Hills, so named by the Indians because of the heavy forests of pine and spruce covering the mountains, include an area of about 5,000 square miles. Considerable fruit is now being raised in this section under irrigation, as the local market is a profitable one, and it has been found possible to raise many varieties not hardy upon the open prairies of the state.



2505. South Dakota, to show horticultural adaptabilities.

The Tablelands comprise the entire section of the state west of the Missouri River, with the exception of the Black Hills. Five branches of the Missouri flow from the western part of the state across these lands from west to east. These are the White, Bad, Cheyenne, Moreau or Owl, and Grand rivers. The series of dry years 1910–11–12–13 show that exclusive grain-farming is not advisable, but the native grasses are very nutritious and stock-raising is profitable.

The Eastern Section contains three river valleys that cross it from north to south, viz., the eastern half of the Missouri, the James River Valley and the Big Sioux River on the eastern border. In the southern part, the valley of the Vermillion traverses the region between the Sioux and James. These river valleys are all very fertile and blend together as they reach the Missouri at the south. Diversified agriculture flourishes in these river valleys, especially in the southern and entire eastern part of this section. In the higher ground in the northern and western part, stock-raising and dairying are the main industries owing to the lesser rainfall. Since the defining of the artesian-well basin, general agriculture has been encroaching upon the grazing areas. This basin reaches from the Missouri River eastward to some distance beyond the James. The amount of this supply which can be used has been roughly estimated at 326,805,600,000 cubic feet annually, an amount of water sufficient to fill a river-bed a mile wide, 20 feet deep and nearly 600 miles long. When this water is more generally utilized, it is confidently believed that the market-gardening and fruit-growing area shown on the map will be enlarged and extended westward.

Horticulture in South Dakota is to a considerable extent still in the experimental stage. Most of the planting of orchard-fruits has been done since the last "crucial test" winter of 1884–5, hence it will be difficult to give a safe list until after the next test winter. A glance at the map will show that the state extends well below the north line of Iowa, and as a matter of fact, it is found that the South Dakota fruit list partakes of both Iowa and Minnesota in its characteristics. The southern tier of counties in the southeast corner of the state can raise varieties of the apple which are not at all hardy northward in the state. It is interesting to trace the orcharding belt along the great river from far down in Missouri northward between Iowa and Nebraska into South Dakota. In the Sioux and James river valleys considerable fruit is grown as far north as the Minnesota line. North of this the orchards are few and far between, the country being new, and grain-raising, stock-raising and dairying affording more profitable sources of income.

The state has been divided into four fruit sections by the State Horticultural Society since 1913, as follows: Northern District—this includes all north of a line running due east and west through Watertown; Central District—this district includes approximately all between two lines running due east and west through Sioux Falls and Watertown; Southern District—this includes all south of the north line of Iowa, which is approximately a line running due east and west through Sioux Falls; the Black Hills District—this includes the Black Hills counties in the southwestern corner of the state.

The largest old apple orchard in the state is in Turner County, consisting of 7,000 trees on about 132 acres. This orchard was planted in the early seventies and is still bearing. About 4,000 of the trees are

Wealthy and most of the remainder Oldenburg. Considerable trouble is experienced from root-killing of the common apple seedling stocks. In the northern part of the state, apple root-grafts root-kill every winter unless deeply mulched. The winter of 1898–9 will long be remembered as the "root-killing" winter by the fruit men of several northwestern states. Efforts are now being made to remedy this trouble by testing the Russian method of preventing root-killing; viz., the use of the pure Siberian crab (*Pyrus baccata*) as a stock. If the experiments are successful, apple-culture will be practicable on the most exposed prairies far up into the Canadian Northwest. In making up a list of apples for planting throughout the state, it will be a safe rule not to plant any variety less hardy than Oldenburg and Wealthy, especially if the planter desires a long-lived fruitful orchard and cannot afford to experiment.

Of plums, those of the *Prunus americana* type, such as De Soto, Wyant, Wolf, Terry and Wastesa, are the standard of hardiness and value for general cultivation. *Prunus americana* is indigenous throughout the state. In recent years, the list of plums has been largely increased by the advent of the hybrids of the native sand cherry and plum with the Japanese plum and Chinese apricot, *Prunus Simonii*, originated at the South Dakota Experiment Station. The main difficulty with plums hitherto has been the tender stocks upon which the hardy natives have been worked. Myrobolan, St. Julian, Marianna, Southern Chickasaw, peach, and other southern stocks all winter-kill, leaving the hardy top to die. Such trees are a snare to the prairie planter, and this fact is becoming more generally known. Trees worked on americana seedlings or trees on their own roots find favor, as no trouble is then experienced from root-killing. The western sand cherry (*Prunus Besseyi*), a native of the state, has been tested as a stock at the Experiment Station at Brookings, but it is of use only as a dwarf stock for amateur use, the trees being dwarfed and bearing fruit at an early age. It is of some promise as a dwarf stock for peaches, such trees being of suitable size for convenient covering in winter or for growing in boxes.

Of other orchard-fruits, pears, quinces, apricots and peaches find no place on the South Dakota fruit list. Cherries are grown to a small extent in the southern counties, but the crop is uncertain in most parts.

Some raspberries can be grown in the southern part with winter protection. Blackberries are not so hardy as raspberries. Strawberries are considerably grown in the southern part of the state, and irrigation is found profitable, as it insures a crop in dry seasons.

Grapes are grown to some extent in the southern part of the state, but northward suffer severely from winter-killing and are not on the fruit list recommended for that part of the state. The Beta, a hybrid of the wild grape, *Vitis riparia* (*vulpina*), of Carver County, Minnesota, with the Concord (*V. Labrusca*), was originated about 1870 by the late Louis Suelter, of Minnesota, and has been found to be much hardier than those of the Concord type and is now largely planted. It appears perfectly hardy without winter protection.

Fruit-breeding at the South Dakota Experiment Station has been carried on under the direction of the Department of Horticulture since 1895. Much work has been done in the breeding of hardy fruits. The frequent winter-killing of varieties brought from milder regions east and south seems to demand the creation of a new prairie pomology. Over 27,000 seedlings of various native fruits were raised at this station in 1889–1890. The wild fruits were crossed with tame whenever possible, but the main reliance was placed upon pure selection, acting upon the theory that "excess of food causes variation." The native species taken in hand in this work include the sand cherry, choke-cherry, pin-cherry, black currant, golden currant, gooseberry, grape, juneberry, plum, red raspberry, black raspberry, strawberry. With the apple, the main effort is to originate a good hardy long-keeping winter apple. Work with several Siberian fruits is also under way. Some of this material was picked up on tours of agricultural exploration to Siberia and adjacent regions. In this work, hundreds of thousands of seedlings have been discarded. Some have not proved amenable to improvement, such as the wild black currant, *Ribes floridum*, which has reached the fifth generation under cultivation without improvement in quality. The same may be said of the native gooseberry, *Ribes gracile*. Fully 100,000 seedlings of the native sand cherry, *Prunus Besseyi*, native especially of the dry uplands of the western part of the state, have been fruited, but only three varieties have been named, the Sioux, Tomahawk, and Champa, with fruit of good size and free from the native astringency. In five plant generations under cultivation, the fruit has been increased to 1 inch in diameter and of good quality. However, the plant is too small in stature, and propagation by budding is expensive; some are being raised by layering. However, the sand cherry displays marked adaptability to hybridization with many species. (See South Dakota Experiment Station Bulletins Nos. 108, 130, and 159.) When mated with the Japanese plum, a series of valuable hybrids have resulted, but hybrids with the peach and the sweet cherry and apricot of Europe are practically sterile. Mating with the purple-leaved plum of Persia, *Prunus cerasifera purpurea*, gives a beautiful purple-leaved shrub. The native plum, *Prunus americana*, is found to mate best with the Japanese plum, the latest result of which is the Waneta, with fruit 2 inches in diameter and weighing two ounces. The native plum is found to mate well with the sand-cherry, giving such hybrids as Sansoto and Cheresoto. The native plum mates best with the Chinese apricot, *Prunus Simonii*, giving fruits with remarkable shipping capacity and with the strong fragrance of the *Prunus Simonii*. Over 10,000 plum seedlings have been raised. The work with the native seedlings was checked with the advent of the hybrids which were found sufficiently hardy. Easily 1,000,000 trees of these new plums are now in the orchards and nurseries of the western states.

After raising 10,000 apple seedlings, none has been introduced with the exception of one crab-apple, the Amur, a seedling of *Pyrus baccata cerasifera*, introduced 1912.

In strawberries, the main work has been to combine the wild types as found in the Dakotas and the Canadian Northwest and Alaska with the standard American varieties and those imported from Europe. Out of 10,000 seedlings but two have been named, the South Dakota No. 1 and No. 2. The fruit is about 1 inch in diameter; the plants are hardy without winter-covering, but must be kept thinned, otherwise the fruit runs too small, as is the case of the wild strawberry from which they sprang.

Out of 13,000 raspberry seedlings, only two, the Sunbeam and Ohta, have been named and introduced. Improvement by pure selection of the wild raspberries of the Dakotas and the Canadian Northwest is slow work, but is not yet given up. The Sunbeam, introduced in 1906, is the first of the 7,000 first seedlings to receive a name. It is a seedling of the wild red raspberry from Cavalier County, North Dakota, near the Manitoba line, pollinated by the Shaffer. From the next 6,000 seedlings came the Ohta, introduced spring of 1912, which is a seedling of the wild red raspberry from Cavalier County, North Dakota, pollinated by Minnetonka Ironclad, a hybrid of the wild raspberry from Maple Plain, Minnesota, with either Turner or Cuthbert.

Pear-culture is at present a practical impossibility either from winter-killing, or from blight (*Bacillus amylovorus*). The work of breeding pears immune to blight is summarized in South Dakota Experiment Station Bulletin No. 159, April, 1915.

An effort has been made to improve the wild prairie rose of the Canadian Northwest, and the Siberian form of *Rosa rugosa*. Out of many seedlings, only one variety, the Tetonkaha, has been disseminated.

Floriculture is still in its early youth, there being but few greenhouses in the state. The rich soil makes it easy to raise large crops of vegetables, but so far, the trucking interests have assumed no importance, except near the larger towns. Agriculture has been extensive, rather than intensive. In a state yielding heavy crops of wheat and other cereals, with a soil so rich that commercial fertilizers are not thought of and barnyard manure so little considered that many farmers prefer to move their barns rather than their manure heaps, and with the burning of straw a common practice, the hoe is rarely seen; gang- and sulky-plows, self-binders and riding-cultivators are the more favored implements. In the course of time, with the increase in population, will come a change in methods. Eastern farmers and gardeners find that the soil and climate demand decided modifications of eastern practices.

Of conifers, the hemlock, white pine, balsam fir, arbor-vitæ and Norway spruce fail in the open prairie, while Jack pine, bull pine, Scotch pine, northern red cedar, western white spruce, and Colorado silver or blue spruce all do well in open exposure. Of deciduous trees, the native species, such as ash, elm, box elder, black wild cherry and hackberry, all do well. Cottonwood and willows do well on moist land. Considerable loss was experienced in the earlier planting from a failure to recognize the fact that species covering a wide geographical range vary greatly in hardiness and that the local indigenous form should be planted when possible.

Many of the hardy pioneer men and women have contributed to the horticultural interests of South Dakota. Among these may be mentioned: Aaron Carpenter, pioneer orchardist and nurseryman; H. C. Warner, who tested many fruits, trees and flowers; Col. C. W. Gurney, pomologist and nurseryman; and A. W. Krueger, for five years president of the State Horticultural Society.

Public-service agencies for horticulture.

The South Dakota College of Agriculture and Mechanic Arts is located at Brookings, and was established in 1881. There is one professor of horticulture.

The Experiment Station is also at Brookings and is in connection with the College. Of the 159 bulletins published by the Station (June, 1915), forty are on horticultural subjects.

The only special school teaching horticulture in the state is the College. However, some horticulture is taught in connection with agriculture in the public schools.

The South Dakota State Horticultural Society is composed of the amateur and professional fruitmen of the state, and was incorporated in 1890. By state law, this Society is made the Department of Horticulture for South Dakota.

Extension work in horticulture is conducted by the College in the form of farmers' institutes and the like.

No inspection service is provided for in fruit-grading. The Department of Entomology of the State College has charge of the inspection service for nurseries.

Statistics (Thirteenth Census).

The approximate land area in 1910 was 49,195,520 acres. The land in farms was 52.9 per cent of the land area, or 26,016,892 acres. Of this land in farms, the improved land numbered 15,827,208 acres, the woodland 383,144 acres, and other unimproved land in farms 9,806,540 acres. The total number of farms in 1910 was 77,644, and the average acreage a farm was 335.1. [The total area of South Dakota is 77,615 square miles.]

The leading agricultural crops of South Dakota are cereals and hay and forage. The acreage devoted to the cereals increased from 6,211,223 in 1899 to 8,203,519 in 1909, when the production was valued at $98,953,050, which was 78.8 per cent of the total value of all crops. Hay and forage increased in acreage from 2,287,875 in 1899 to 3,435,656 in 1909, when the production was valued at $15,243,664. In 1909, from 518,566 acres, there were harvested 4,759,794 bushels of flaxseed, valued at $7,001,717. The value of the forest products of the farms in 1909 was $257,126, as compared with $106,284 in 1899.

Horticultural crops grown in South Dakota are fruits and nuts, small-fruits, potatoes and vegetables, and flowers, plants, and nursery products. The value of the fruits and nuts produced in 1909 was $215,639, as compared with $31,964, in 1899. Small-fruits increased in acreage from 161 in 1899 to 419 in 1909, when the production was 401,295 quarts, valued at $47,263. The total acreage of potatoes and other vegetables in 1909 was 65,209, and their value, $3,001,574. Excluding potatoes, the acreage of other vegetables increased from 7,954 in 1899 to 15,150 in 1909, when the production was valued at $1,033,163. Flowers, plants, and nursery products increased in acreage from 211 in 1899 to 418 in 1909, when the value of the production was $120,835.

The total quantity of orchard fruits produced in 1909 was 229,907 bushels, valued at $209,339. Apples contributed about five-sixths of this quantity, plums and prunes most of the remainder. The production of apples in 1909 was 191,784 bushels, valued at $158,729. The number of apple trees of bearing age in 1910 numbered 274,862; those not of bearing age, 460,547. The plum and prune trees of bearing age in 1910 numbered 268,268, and those not of bearing age, 172,186. The production in 1909 was 31,748 bushels, valued at $36,872. Cherry trees of bearing age in 1910 numbered 51,613; those not of bearing age, 76,293. The production in 1909 was 5,924 bushels, valued at $12,981. Other orchard-fruits produced in 1909 were 162 bushels of pears, valued at $447; 148 bushels of peaches and nectarines, valued at $167; and 120 bushels of mulberries, valued at $123. The value of the apricots and quinces was of little or no importance.

The production of grapes in 1909 was 144,634 pounds, valued at $4,789. The grape-vines of bearing age in 1909 numbered 38,647; those not of bearing age, 46,891.

The production of nuts in 1909 was 73,715 pounds, valued at $1,511. The only important nut in South Dakota in 1909 was the black walnut, the production of this alone being 72,659 pounds, valued at $1,490.

Of the small-fruits grown in South Dakota, strawberries are the most important, with raspberries and loganberries ranking next. The acreage of strawberries increased from 62 in 1899 to 226 in 1909, when the production was 238,164 quarts, valued at $26,764. Raspberries increased in acreage from 21 in 1899 to 66 in 1909, when the production was 60,285 quarts, valued at $8,703. Currants increased in acreage from 38 in 1899 to 67 in 1909, when the production was 52,951 quarts, valued at $6,021. Gooseberries increased in acreage from 25 in 1899 to 55 in 1909, when the production was 43,408 quarts, valued at $4,926. Other small-fruits produced in 1909 were 6,058 quarts of blackberries and dewberries, valued at $809; and 288 quarts of cranberries, valued at $25.

The acreage of potatoes increased from 33,567 in 1899 to 50,052 in 1909, when the production was 3,441,692 bushels, valued at $1,967,550. The more important of the other vegetables produced were: 175 acres of cabbage, valued at $13,759; 104 acres of onions, valued at $13,133; 579 acres of sweet corn, valued at

$12,018; 212 acres of watermelons, valued at $10,625; and 62 acres of tomatoes, valued at $4,335. Vegetables of lesser importance produced in 1909 were: asparagus, green beans, cantaloupes and muskmelons, pop-corn, green peas, and turnips.

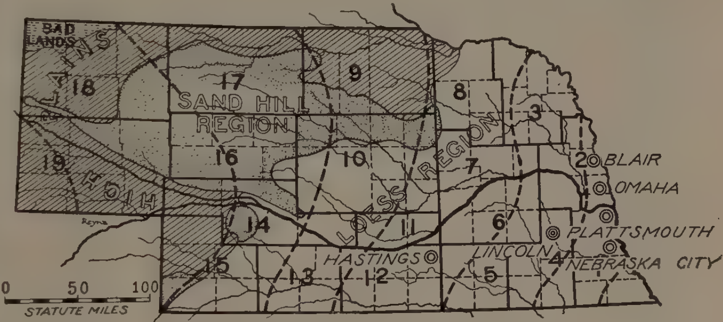
The acreage devoted to the growing of flowers and plants increased from 11 in 1899 to 19 in 1909. The total acrea under glass in 1909 was 101,460 square feet, of which 92,240 were covered by greenhouses, and 9,220 by sashes and frames. The value of the flowers and plants produced in 1909 was $50,008, as compared with $3,260, in 1899.

The acreage devoted to nursery products increased from 200 in 1899 to 399 in 1909, when the production was valued at $70,827, as compared with $12,866, in 1899.

N. E. Hansen.

Nebraska.

The state of Nebraska (Fig. 2506) presents a variety of horticultural conditions, owing to the varied topography, the diversity of soil, and the wide range of altitude and climate. The eastern part of the state is rolling prairie, the great loess plains, broken and almost rough, near the Missouri River. The soil is deep and fertile and the undulating surface amply provides both soil and atmospheric drainage. The central part of the state has a more uniform surface but is subject to a high rate of evaporation, owing to dry winds. In the west-central part of the state lie the sand hills where the soil is very light, though many fertile valleys lie between the hills, and the rate of evaporation is equally high. South of the sand hills are prairie lands or loess plains where irrigation is practised to some extent. South and west lie high prairies or the Cheyenne plains. Several extensive orchards are grown here under irrigation. To the north and west are the buttes and "bad lands." The elevation of the southeastern part of the state is 850 feet at its lowest point in Richardson County and averages 1,200 feet along the entire eastern part of the state close to the Missouri River, while the extreme western part exceeds 5,000 feet. The rainfall gradually decreases from east to west, as the elevation increases. Nebraska is fortunate in that the rainfall is greatest when most needed for agriculture, namely, April, May, June and July. Because of the great diversity of conditions, the State Horticultural Society has divided the state into nineteen districts, as indicated on the accompanying map, which are generally considered in making recommendations for fruit-culture.



2506. Nebraska, showing the various areas or districts.

Apples form the most important horticultural crop, but, except under irrigation, are grown commercially principally in the southeastern half of the state, known as the Great Loess region. However, commercial orcharding is gradually extending westward. Commercial orcharding under irrigation is being carried on in the central, southern, and western parts of the state, principally in Lincoln, Scott's Bluff and Red Willow counties.

District No. 1 is perhaps the best apple-growing region of the state. Here is the natural home of the Jonathan apple, where it attains its highest degree of excellence. Other standard varieties thrive almost as well. Perhaps more Ben Davis apples are shipped from this section than from any other part of the state. The rainfall is ample and well distributed throughout the year. The large amount of bright sunlight during the time when most of the fruit is ripening perhaps accounts for the high color, good quality and excellent keeping properties of Nebraska fruit. District No. 2 follows No. 1 so closely in amount and quality of apples grown that the region might well be known as one district, the chief difference being that the former has a rougher surface, higher altitude, and lies farther north, making injury from frost more liable. Districts Nos. 3, 4, 5, 6, 7, 8, 11 and 12, while not so favorably located, lie within the commercial apple district and produce immense quantities of excellent fruit. Districts Nos. 9, 10, 13 and 14 require careful cultural methods, but with proper care apples are grown successfully, though perhaps other farm crops, with live-stock, will give larger returns than commercial orcharding. However, the home orchard, well cared for, is one of the greatest assets of the farmstead.

Throughout the remainder of the state, much care must be exercised in the propagation of apples except under irrigation, although there are many thriving home-orchards. The dry seasons, prevailing light soil, and cold winters, especially in the northwestern part of the state, make winter-killing liable.

The Winesap is the favorite commercial variety the state over, with the Jonathan as a close second and Ben Davis third. The dry weather of the last three seasons, with the severe winter of 1911, and the severe attack of Illinois canker has proved fatal to many Ben Davis trees. The Jonathan apple is grown in the southern part of the state, where it has attained a world-wide reputation. Other varieties which thrive in this state are: Summer—Duchess, Yellow Transparent, Cooper's Early White, Coles Quince, Early Harvest, Sweet June, Red Astrachan, Chenango Strawberry, and Red June; autumn—Wealthy, Utter's Red, Maiden's Blush, Fulton Strawberry, Flora Belle, Plum Cider, Fameuse, Porter and McMahon's White; winter—Gano, Windsor, Grimes' Golden, Janet, Northwestern Greening, Black Twig, Ingraham, Missouri Pippin and Iowa Blush.

Pears are successfully grown throughout the southeastern part of the state, though few large commercial orchards exist. The trees are liable to winter-kill if planted too far north and west, while susceptibility to fire blight is the controlling factor in the southeast. The principal varieties are Kieffer, Bartlett, Sheldon, Flemish Beauty and Seckel.

Native plums thrive over the entire state while European and Japanese varieties do well in the eastern and southern parts. American varieties are, Wyant, Wolf, Wild Goose, Forest Garden and DeSota; European—Lombara, Shipper's Pride, Green Gage, Shropshire Damson; Japanese—Burbank, Abundance and Wickson.

Peach-growing, commercially, is confined to the southeastern part of the state, where excellent crops are occasionally produced. The greatest difficulty lies in the late frosts which sometimes destroy the crops, and the liability to winter-killing of the fruit-buds, though some peaches are raised every year. Alexander, Early Rivers, Triumph, Russel, Champion, Bokara, Crosby, Hill's Chili, Heath Cling, Solway and Wright are the principal varieties.

Cherries thrive over the greater part of the state and are remarkably free from insect and fungous injuries. Besides the native cherries, Early Richmond, Montmorency and English Morello are the leading varieties.

Grape- and small-fruit-growing is becoming one of the leading industries in the eastern part of the state, especially in Districts Nos. 1 and 2, where much wine is manufactured and immense quantities of fruit shipped out every year. The grape has been exceptionally free from insect and fungous enemies until very recently when black-rot and the grape root-worm have caused serious losses in some localities. The leading varieties are Concord, Worden, Moore Early, Niagara, Moore's Diamond, and Woodruff Red.

Raspberries and blackberries suffer from drought and winter-killing except in the region close to the Missouri River, and here they form an important crop. Red raspberries are very little grown, being subject to winter-killing except in the immediate vicinity of the rivers. Strawberries now form one of the most important small-fruit crops in the eastern part of the state, especially in Districts Nos. 1 and 2 where fruit of the highest quality is produced. Senator Dunlap, Splendid, Bederwood, Crescent, Gandy, August Luther, Klondike, July and Sample are the varieties principally grown.

The nursery interests of the state are very important. Seedlings of all the important fruit, forest and shade trees are grown in large quantities. Propagation of varieties is carried on by root-grafting, budding and hardwood cuttings. The nurseries of the state supply not only the home trade but have a large and well-established business in other states.

Vegetable-gardening has taken its rightful place with the other industries in Nebraska. Both vegetables grown in the field and under glass yield abundantly and are of excellent quality. More vegetable-gardening is done in District No. 2 than any other part of the state, although the irrigated lands in the Scottsbluff region are rapidly developing into a vegetable-producing section. Canneries are being established and the indications are that there will be a still more rapid increase in vegetable-growing in the near future. The beet-sugar factories afford a ready market for sugar-beets, the acreage of which is rapidly increasing. The acreage planted to potatoes each year is also rapidly increasing in spite of potato diseases and occasional droughts. Marketing associations are being formed at various points to facilitate the distribution. Early varieties are grown principally, the leading potato being the Early Ohio. Many acres of tomatoes are grown every year and sold to the canneries. All varieties of root crops do well throughout the state, but the cucurbits are grown with most satisfactory results only on sandy loam soil of the Platte River valley, and a few other particularly suitable locations. The growing of pure-bred garden seeds also receives a great deal of attention.

Ornamental gardening and floriculture are receiving their due share of attention throughout the state, especially about the cities. The excellent markets have made greenhouse work very popular and a large number of persons receive employment in this line.

Among the native wild fruits which are found abundantly along every stream, the following are the most common: Pawpaw (*Asimina triloba*), in the eastern part; late wild grape (*Vitis cordifolia*), over the entire state; early wild grape (*Vitis riparia*), over the entire state, the latter ripening much earlier than the former and being much more palatable; wild plum (*Prunus americana*), over the entire state; choke-cherry (*Prunus virginiana*), over the entire state; wild cherry (*Prunus serotina*), eastern part of state; sand cherry (*Prunus pumila*), very common in the central and western parts of the state on dry sandy lands; wild cherry (*Prunus demissa*), common throughout the region from "Long Pine" westward and is much more palatable than the choke-cherry; wild strawberry (*Fragaria virginiana* var. *illinoensis*),. very common wherever moisture is sufficient; wild red raspberry (*Rubus strigosus*), in the eastern part of the state; wild black raspberry (*Rubus occidentalis*), very common over eastern half of state; wild blackberry, very common over eastern half of state; wild crab-apple (*Pyrus coronaria*), eastern part of the state; juneberry (*Amelanchier canadensis*), in the eastern part of the state; wild gooseberry (*Ribes rotundifolium*), very common in the eastern part of the state; golden currant (*Ribes aureum*), very common; elder (*Sambucus racemosa*), very common; persimmon (*Diospyrus virginiana*), southeastern part; buffalo berry (*Shepherdia argentea*), along Platte River; red mulberry (*Morus rubra*), in the eastern part.

Early horticulture in Nebraska was very discouraging. Persons coming to Nebraska and not acquainted with conditions insisted on planting varieties of trees unsuitable to this region, because of their excellence on the old "home place," or, being entirely unfamiliar with the varieties, allowed some eastern nurseryman to choose for them. The results were such that further planting was discouraged. The deep fertile soils of Nebraska produced such abundant crops of corn and small grain that orchard-planting was retarded. The trees were as a rule set too close together, and in the rush of general farming, neglected. Young trees were set in sod and if they reached the age of bearing soon bore themselves to death. Added to this came the inroads of insects and fungous diseases. But here, as in the face of other great dangers, leaders were developed, men with courage and determination who have succeeded in overcoming many of the difficulties. Systematic spraying was commenced. Scientific pruning and cultural methods were developed.

Nebraska has awakened from her lethargy and has become a state of pioneers in horticulture. Amateur horticulturists are numerous and horticultural specialties are rapidly developing. Better methods have developed special crops. Canning factories have been established and plants for the handling of by-products, such as cider-mills, vinegar-factories, wine-presses, and the like are numerous throughout the state.

The present high rank of horticulture in Nebraska is due largely to the untiring efforts of the early pioneers who not only planted large numbers of fruit trees themselves, but encouraged and assisted others to do the same. Among these may be mentioned: W. J. Armstrong, of Otoe County; J. Sterling Morton, who besides fruit-trees planted trees and shrubs of every species and variety which he thought would thrive in the vicinity of Nebraska City; he was the originator of Arbor Day, and to him is due in a large part many of the beautiful plantings and groves of trees found in the state today; Oliver Harmon, who planted not only fruit-trees and vines but forest trees as well; J. H. Masters, who besides extensive plantings of fruit and forest trees, engaged heartily in beekeeping; Wm. Fulton, who planted an orchard near Nebraska City; Benton Aldrich, who planted apple and peach orchards in Nemaha County, near Auburn; Joseph Bennett; Bird Vowell, who planted orchards near Auburn; S. Barnard, who established a nursery and planted an orchard at Table Rock; R. W. Furnas, ex-Governor of Nebraska, who planted a large orchard near Brownville, and carried on many experiments; J. M. Russell, who planted a peach orchard near Wymore, and who, besides demonstrating that peaches could be grown in Nebraska, originated many excellent varieties.

Public-service agencies for horticulture.

The Land-Grant college of Nebraska was established at Lincoln in 1871. There are three teaching members of the horticultural staff.

The Experiment Station is also located at Lincoln. There are also two experimental substations, the North Platte Experimental Substation, 4 miles south of the city of North Platte, and the Valentine Experimental Sub-station, near the town of Valentine.

In addition to the work done at the College of Agriculture, horticulture is now being taught at the State Normal schools of Peru and Kearney, the School of Agriculture at Curtis, and in connection with agriculture in almost every high-school in the state.

Extension work is conducted in connection with the College, one man devoting his entire time to this work.

The Nebraska State Horticultural Society was organized in 1869, with J. H. Masters as first president. Local fruit-growers' associations have been formed in all the leading districts, and in 1912 the Eastern Nebraska Fruit-Growers' Association was formed. A uniform system of packing and grading has been adopted which, with the present shipping facilities, insures proper distribution and good prices for horticultural products.

Statistics (*Thirteenth Census*).

The approximate land area of Nebraska in 1910 was 49,157,120 acres. The land in farms was 78.6 per cent of the land area, or 38,622,021 acres. Of this land in farms 24,382,557 acres were improved; 803,206 were woodland; and other unimproved land in farms numbered 13,436,238 acres. The number of all the farms in 1910 was 129,678. The average acreage to a farm was 297.8. [The total area of the state is 77,520 square miles.]

The leading agricultural crops of Nebraska are cereals and hay and forage. The acreage of cereals increased from 12,071,703 in 1899 to 12,540,049 in 1909, when the value of the cereals produced was $153,666,652, or 78.3 per cent of the total value of all crops. The acreage occupied by hay and forage increased from 2,823,652 in 1899 to 4,520,034 in 1909, when the value of the hay and forage produced was $31,729,691, or 16.2 per cent of the total value of all crops. In 1909 sugar crops were produced, from 8,225 acres, to the value of $241,272, the acreage being a decrease, however, of 38.8 per cent from that of 1899. The forest products of farms in 1909 was valued at $795,053, as compared with $412,746 in 1899.

Horticultural crops produced in Nebraska are fruits and nuts, small-fruits, vegetables including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $2,078,340, as compared with $761,053 in 1899. Small-fruits increased in acreage from 1,171 in 1899 to 1,411 in 1909, an increase of 20.5 per cent, when 1,594,421 quarts were produced, valued at $159,169. In 1909 the total acreage of potatoes and other vegetables was 147,594 and their value $5,931,738. Excluding potatoes and sweet potatoes and yams, the acreage of other vegetables increased from 34,532 in 1899 to 36,164 in 1909, when the value of the vegetable products was $2,118,393. Flowers and plants and nursery products increased in acreage from 1,680 in 1899 to 2,091 in 1909, when the value of the products was $909,221.

The total production of orchard fruits in 1909 was 3,572,253 bushels, valued at $1,932,124. More than nine-tenths of this quantity was produced by apples, and most of the remainder by peaches and nectarines and cherries. The apple trees of bearing age in 1910 were 2,937,178; those not of bearing age 967,133; and the production in 1909 was 3,321,073 bushels, valued at $1,612,765. Peach and nectarine trees of bearing age in 1910 numbered 1,188,373; those not of bearing age 263,882; and the production in 1909 was 110,180 bushels, valued at $91,129. Cherry trees of bearing age in 1910 numbered 494,468; those not of bearing age, 267,529; and the production of cherries in 1909 was 89,876 bushels, valued at $164,872. Other orchard-fruits produced in 1909 were: 6,700 bushels of pears, valued at $9,802; 41,910 bushels of plums and prunes, valued at $50,934; 864 bushels of apricots, valued at $1,229; 995 bushels of quinces, valued at $993; and 665 bushels of mulberries, valued at $400.

The production of grapes in 1909 amounted to 4,752,217 pounds, valued at $137,295. The grape-vines of bearing age in 1910 numbered 1,221,736; those not of bearing age, 380,788.

Nuts were produced in Nebraska in 1909 to the amount of 384,325 pounds, valued at $8,906. The black walnut is the only nut of importance, the production in 1909 being 381,968 pounds, valued at $8,740.

Of the small-fruits grown in Nebraska, strawberries are the most important, with blackberries and dewberries second. The acreage of strawberries increased from 369 in 1899 to 562 in 1909, when the production was 654,061 quarts, valued at $65,772. Blackberries and dewberries increased in acreage from 152 in 1899 to 428 in 1909, when the production was 501,872 quarts, valued at $46,648. The production of raspberries and loganberries was 265,183 quarts, valued at $29,841; that of currants 90,779 quarts, valued at $8,592; and that of gooseberries 82,086 quarts, valued at $8,259.

The acreage devoted to potatoes increased from 79,901 in 1899 to 111,151 in 1909, when the production was 8,117,775 bushels, valued at $3,785,224. The acreage of sweet potatoes and yams decreased from 551 in 1899 to 279 in 1909, when the production was 28,500 bushels, valued at $28,121. The more important of the other vegetables produced were 3,167 acres of sweet corn, valued at $46,208; 725 acres of watermelons, valued at $36,223; 2,167 acres of pop-corn, valued at $33,854; 348 acres of cabbage, valued at $27,144; 282 acres of tomatoes, valued at $21,012; and 163 acres of onions, valued at $18,659. Vegetable of lesser importance were asparagus, cantaloupes and muskmelons, celery, cucumbers, squash, and turnips.

The acreage devoted to flowers and plants increased from 86 in 1899 to 94 in 1909. The total area under glass in 1909 was 844,010 square feet, of which 790,305 were covered by greenhouses, and 53,705 by sashes and frames. The value of the flowers and plants in 1909 was $356,168, as compared with $142,636 in 1899.

The acreage devoted to nursery products increased from 1,594 in 1899 to 1,997 in 1909, an increase of 25.3 per cent. The value of the nursery products in 1909 was $553,053, as compared with $234,033, in 1899.

J. R. Cooper.

Kansas.

The commercial horticulture of Kansas (Fig. 2507) is in large part centralized in a few localities. Twenty-five counties produced about nine-tenths of the 10,000 carloads of apples sold in 1912. The last tenth is grown in many scattered localities that are especially suited for horticultural work, sheltered valleys where the soil is deep, rich and always moist. In nearly every one of the remaining eighty counties successful fruit and vegetable plantations may be found. Sixty counties contributed more than two carloads of peaches to the total of 1,300 carloads sold in 1912. Thirty counties contributed one or more carloads of strawberries to the total of 300 cars sold in 1913.

Two sections of the state have large areas of land particularly suitable for horticultural products. The northeastern counties have a considerable area of glacial soils that is well suited to fruit-growing and in which the area devoted to fruit may be expected to increase constantly. The Arkansas Valley has a large acreage of sandy loam underlaid with a porous clay subsoil which has proved to be well suited to fruit-growing. The inexhaustible supply of water which may be cheaply secured for irrigation by pumping has recently been utilized in commercial orchards and gardens and the possibilities of this region are not easily estimated.

A large proportion of Kansas will for long years to come be devoted to grain- and stock-farming. Thousands of acres well suited to fruit and truck crops are devoted to corn, wheat, alfalfa, and grass. Fruit- and truck-farmers may be found prospering near every city and large quantities of their products are shipped from many points in the northeast counties and the Arkansas Valley towns.

The early fruit-growers planted large numbers of varieties that proved to be poorly suited to Kansas climate. Such standard eastern varieties as Hubbardston, Northern Spy, Baldwin and Rhode Island Greening ripened prematurely and had to compete with the fall varieties. These have been dropped from the list of recommended varieties. In this era of elimination the varieties which have been retained are those that have generally proved productive and profitable. Grimes', Jonathan, Winesap, York Imperial, Stayman, Arkansas or Black Twig, can compete in any market for the highest prices.

In the northeastern counties, most of the orchards are kept in clover or orchard-grass much of the time, to prevent erosion. That these deep moist soils are well adapted to this system of management is indicated by the successful crops borne in seasons when the rainfall is much below the normal. In the Arkansas Valley clean cultivation and cover-crops are the rule.

The barrel is the favorite package and a large part of the crop finds a market in the cities and towns of the states north and east. Barreling in the orchard is a common method, and the fine autumn weather usually occurring in this section makes this an economical practice. The fruit from the Arkansas Valley orchards is graded more closely as a rule, and the grades, fancy and extra fancy, packed in bushel boxes for the southern and southeastern markets. The fruit below fancy grades usually has found a ready market in the "wheat country" of the central and western part of this state and the "cotton belt" of Oklahoma and northern Texas. Some of the more isolated orchards have sold their entire crop to the "wagon trade" from surrounding farm country. The fancy grades compete in any market with the best grown anywhere. Grimes, Jonathan, Rome Beauty, and Winesap are the quality apples of Kansas and nowhere do they reach a higher degree of perfection.

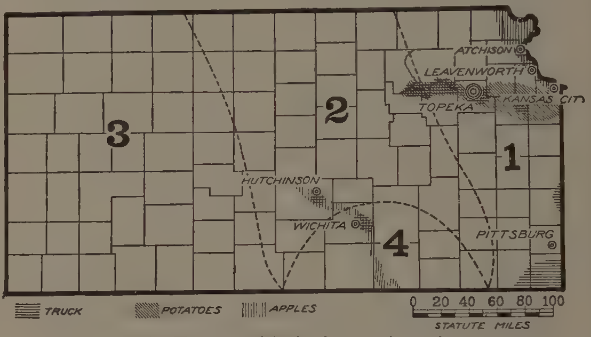
Early apples are increasing in favor with the Arkansas Valley growers. Good markets have been the rule, and this section can send good pie stock to market by July 1 and good dessert apples by July 15. Early Harvest and Red June have been largely replaced by Yellow Transparent, Cooper, and Wealthy. Maiden Blush is still in favor and Liveland Raspberry is being set in considerable numbers.

In spite of the erratic climatic conditions, peaches are grown in many counties. The Kansas grower sets peaches with the expectation that late frosts will injure at least half the crop in the northern half of the state and one-third in the southern half, but even with such losses occurring, when well cared for, peaches give good returns. Elberta has been more generally planted than any other variety, owing to its desirability as a shipper and canner, but many growers who supply local markets plant a number of varieties. Amsden, Champion, Greensboro, Triumph, Carmen, Mountain Rose, Crawford, Bonanza, Solway, Family Favorite, and Crosby have been generally successful. Many farmers still plant seedlings in a small way.

Sour cherries and the cultivated native plums are successfully grown in a variety of soils, but large plantings are seldom set. The Labrusca varieties of grape are particularly successful in the northeastern counties, and the vineyard acreage is increasing. In the southern counties the Labrusca varieties are to some extent being succeeded by some of Munsen's hybrids of *Vitis Lincecumii*.

The acreage of small-fruits has fluctuated in some sections, but the total acreage has steadily increased. Wathena and Troy in Doniphan County have made larger shipments than any other points, but large quantities are marketed locally by growers near the larger cities and towns.

Potatoes and sweet potatoes are shipped from the state in considerable quantities. The sandy soils of the Kansas and the Arkansas valleys produce most of the carlot shipments. Both Irish and sweet potatoes are grown for local market in most of the counties and a large part of the Irish potato crop is dug early and sold as new potatoes. The acreage devoted to sweet potatoes increases steadily. The northern and western markets seem to prefer the dry-fleshed potato from Kansas to the moister varieties of the South. The Yellow Jersey is the most widely grown, the short, well-shaped roots developing early giving the growers a chance at the early markets North and West, and a considerable part of the crop is dug and shipped for this early trade. This practice of selling early accounts, in a large measure, for the low-acre yields often reported by growers of Irish and of sweet potatoes, while the profit an acre compares well with other localities.



2507. Kansas, with the four main regions.

Several localities in southern Kansas have developed an extensive trade in vegetables with Oklahoma and Texas towns, shipping corn, tomatoes and melons south after their early truck crops have been marketed.

Watermelons are grown on a large scale in many localities. In earlier years the watermelon crop was uncertain owing to the injury from the melon louse, which infested fields where the crops were grown continuously for a number of years. With the general adoption of a reasonable rotation, Kansas is a regular factor in the late melon market. The difficulty of having the soil sufficiently rich for melons and not over strong for sweet potatoes is met by using corn or Irish potatoes or tomatoes between melons and sweet potatoes. Alfalfa is now being grown on soils that a few years ago were considered hopeless for that crop. Manure is an essential in getting alfalfa started in these sandy soils, but, once started, it yields well and the soil can be made ready for melons. One great value of alfalfa as a crop to precede melons is the comparative freedom from weeds.

Near Kansas City, Leavenworth, Atchison, Topeka, and Wichita, a considerable interest in cut-flower crops is being developed, and many of the smaller cities afford good support to local florists. Near the larger cities an increasing industry is the summer crop of cut-flowers. Peonies for the Memorial Day trade are gaining in favor and thousands of buds are held in cold storage for this demand. Gladioli and summer crops of roses usually prove fairly profitable.

The nursery business has long been important in this state. For years large areas of apple seedlings have been grown in the Kansas River Valley. The deep, strong soil produces a very high-grade stock and growers are improving their methods, generally using alfalfa in rotation chosen to secure the best possible condition of soil. The state ships many carloads of nursery stock other than apple stock and the trade increases steadily.

The forest tree nursery business has changed considerably in recent years. In the early days of the "Timber Culture Act," when a settler might secure a quarter-section of land for planting 10 acres of the tract to trees, any sort of tree seedling could be profitably grown. Those were the days of the enthusiasm for the "hedge fence," and millions of osage orange seedlings were grown. Today the hedge is in disrepute. The cost of careful maintenance is high in labor, and the cost of neglect is high in injury to the fields, and Kansas hedges are the victim of the stump-puller. The catalpa is still set for posts and poles, and is on a safer basis than in former years. The lesson of the worthlessness of all species except *Catalpa speciosa* was an expensive one. The fact that it is not well adapted to high dry soil has been demonstrated, as has its value for rich moist soil, and lands subject to overflow are being planted to catalpa and walnut. Many settlers who planted cottonwood as roadside trees thirty or more years ago are sawing lumber and finding that the cottonwoods pay rent for the land. The Kansas farmers are planting better trees than they did a generation ago. The box elder, soft maple, and poplars have given way to elms, hackberry, sycamore, oaks, walnut, and pecan in the eastern section, and the honey locust, elms, hackberry, osage orange, and Russian olive have proved valuable in even the drier soils. The red cedar is the only native evergreen, and since it has been shown that a two-year stratification or mechanical removal of the gummy coat makes its propagation fairly certain, it has been grown more largely than ever before. It is one of the most adaptable trees in the list, growing in every county in Kansas. The bull pine or western yellow pine, *Pinus ponderosa*, is well suited, and the Austrian and the Scotch pines are good trees for Kansas.

In the boom days of Kansas every citizen felt in duty bound to believe that every crop of the temperate regions could be grown here with less effort than elsewhere and that all the varieties of soil were equally fertile. The modern Kansan is learning that the great variety of soils and conditions gives opportunity for many lines of agricultural industry and that the welfare of the state is best secured by using crops best suited to soil and conditions. The men who have succeeded in the various lines of horticulture have done so by using the natural resources in a rational way. Some of the big orchards set in the early days on suitable soils have proved to be valuable properties, but careful work has been given them. Others set in a spirit of speculation with no investigation of soil suitability or with little idea of the value of varieties have not been particularly profitable.

Public-service agencies for horticulture.

The State Agricultural College is at Manhattan, and has from its earliest years maintained a Department of Horticulture. For some years the work in entomology was combined with that of horticulture and the two lines of work have always been closely associated. Experiments in the control of fruit insects were one of the first lines of activity undertaken when the Experiment Station was founded in 1887.

The Extension Division of the College has maintained a publicity bureau that has done much in getting buyers and producers of fruit into communication. The College renders considerable service in the matter of civic improvement, members of the staff visiting many localities delivering lectures, making suggestions and preparing plans for parks, cemeteries and the grounds for public buildings.

In several localities coöperative associations have been formed for the promotion of horticultural interests. The Wathena Fruit Growers' Association is the largest, shipping each season hundreds of carloads of fruit grown by its members.

The State Horticultural Society in its fifty years of service has accumulated a wealth of information that is proving to be a safe foundation for horticultural enterprises. There are a number of county and local horticultural societies which have served their communities faithfully and well.

Statistics (Thirteenth Census).

The approximate land area in 1910 was 52,335,360 acres; the land in farms 43,384,799 acres, or 82.9 per cent of the land area. The improved land in farms was 29,904,067 acres, or 68.9 per cent of the land area in farms. There were 1,205,910 acres of woodland in the farms and 12,274,822 acres of other unimproved land in farms. The total number of farms in Kansas in 1910 was 177,841. The average number of acres to a farm was 244. [The total area of Kansas is 82,158 square miles.]

The leading agricultural crops of Kansas are cereals and hay and forage. Of the total value of all crops in 1909, 78.7 per cent was contributed by cereals and 14.9 per cent by hay and forage. The acreage of cereals increased from 13,326,940 in 1899 to 15,638,669 in 1909, when the value of the production was $169,109,449. Hay and forage decreased in acreage from 4,337,342 in 1899 to 3,957,745 in 1909 when the production was valued at $32,033,954. Broom-corn was produced to the value of $593,947 in 1909, and sugar crops to the value of $508,024. The value of the forest products of the farms in 1909 was $1,336,950, as compared with $837,997, their value in 1899.

Horticultural crops grown in Kansas are fruits and nuts, small-fruits in a limited amount, vegetables to quite a large extent and flowers and plants and nursery products. The value of all fruits and nuts produced in Kansas in 1909 was $1,136,977, as compared with $2,031,406 in 1899. The acreage occupied by the small-fruits decreased 7.3 per cent, from 5,824 acres in 1899 to 5,400 acres in 1900, when the production was 5,477,274 quarts, valued at $454,200. Vegetables, including potatoes, occupied, in 1909, an acreage of 132,665 and the value of their products was $6,808,653. The raising of flowers and plants and nursery products is of some importance in Kansas, 4,164 acres being devoted to them in 1909, with an output valued at $1,222,208.

The production of all orchard fruits was 58.8 per cent less in 1909 than in 1899. The total production of orchard fruits in 1909 was 1,447,849 bushels, valued at $944,631. Apples produced more than nine-tenths of this quantity, with cherries ranking next in importance. The apple trees of bearing age in 1910 numbered 6,929,673; those not of bearing age 1,116,316. The production in 1909 was 1,356,438 bushels, valued at $807,865. Cherry trees of bearing age in 1910 numbered 661,267; those not of bearing age, 237,051. The production in 1909 was 34,409 bushels, valued at $76,734. Quantities of other fruits grown in 1909 were 24,567 bushels of peaches and nectarines, valued at $23,418; 19,412 bushels of pears, valued at $21,543, and 12,250 bushels of plums and prunes, valued at $14,001. In addition, small quantities of quinces apricots and mulberries were produced.

The production of grapes declined from 15,786,019 pounds with a value of $297,000 in 1899 to a production of 6,317,684 pounds with a value of $184,673 in 1909. The number of grape-vines of bearing age in 1910 was 2,889,845; those not of bearing age numbered 343,002.

The production of nuts in Kansas is of minor importance. In 1909 the most important nut was the black walnut, of which 377,649 pounds were produced, valued at $6,033. The other nut of importance is the pecan, of which 20,583 pounds were produced in 1909, valued at $1,462. In addition, 3,950 pounds of hickory-nuts, valued at $107, and 275 pounds of chestnuts, valued at $19, were produced in 1909.

Blackberries and dewberries are the most important of the small-fruits raised in Kansas, with strawberries second in importance. The acreage of blackberries and dewberries increased from 2,044 in 1899 to 2,682 in 1909, when the production was 2,535,918 quarts, valued at $201,134. The acreage of strawberries decreased in the same period from 2,304 in 1899, to 1,719 in 1909, when the production was 2,119,048 quarts, valued at $178,094. The productions of other berries of importance in 1909 were: 616,035 quarts of raspberries and loganberries, valued at $56,446; 138,772 quarts of gooseberries, valued at $12,460; and 67,005 quarts of currants, valued at $6,023.

Among the vegetables, the potato is by far the most important. In 1909 the acreage devoted to potatoes was 79,025 from which were produced 5,647,049 bushels, valued at $3,471,488, more than the value of all the other vegetables. The more important of the other vegetables, their acreage, and value of their products in 1909 follow: sweet potatoes and yams, 4,883 acres, valued at $373,432; watermelons, 3,317 acres, valued at $131,527; tomatoes, 1,237 acres, valued at $84,937; sweet corn, 3,653 acres, valued at $75,499; cabbage, 1,007 acres, valued at $55,812; and onions, 243 acres, valued at $29,753. Other vegetables grown were asparagus, green beans, cantaloupes and muskmelons, pop-corn, cucumbers, lettuce, green peas, rhubarb, and turnips.

The acreage devoted to the growth of flowers and plants increased from 75 in 1899 to 161 in 1909. The total area under glass in 1909 was 781,498 square feet, of which 728,421 were covered by greenhouses and 53,077 by sashes and frames. The value of the plants and flowers produced in 1909 was $273,715, as compared with $79,765, their value in 1899.

The acreage devoted to the growth of nursery products increased from 3,449 acres in 1899 to 4,003 acres in 1909, an increase of 16.1 per cent. The value of the nursery products in 1909 was $948,493, as compared with $447,053 in 1899. ALBERT DICKENS.

SOUTH ATLANTIC STATES.

Delaware.

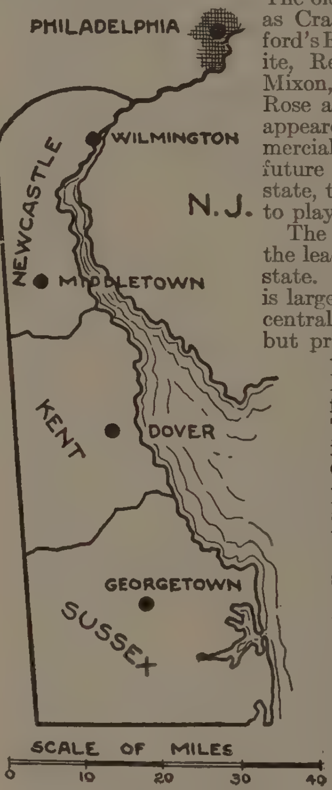
Geographically, Delaware (Fig. 2508) is divided into three counties, New Castle in the north, Kent in the center and Sussex in the south. Geologically, there are but two distinct regions, Piedmont, and Atlantic coastal plain. New Castle, the northern county, lies partially in the Piedmont region and partially in the coastal plain region, the northern portion being hilly and of a rolling topography and the remainder gently rolling with a gentle slope to south and east. The remainder of the state has no elevations of any consequence, the surface varying from slightly rolling in the north to flat, nearly level lands in the south. All along the eastern side of the state, many inlets and short navigable streams indent the coast. A narrow stretch of marshlands borders the coast from north to south. The greater part of the state lies below 100 feet above sea-level and the southern half lies below the 50 feet contour.

The soils of the state are well diversified; yet for the most part they are fertile and especially adapted to fruit- and vegetable-culture. The soil types of New Castle County vary greatly, while those of the other two counties are rather uniform. The principal soil types of Kent and Sussex counties are those of the Norfolk and Portsmouth series, viz., Norfolk loams and sands, and Portsmouth loams and sands.

The climate of the state is mild, the temperature, except in the extreme northern part, seldom falling below zero in winter. The close proximity of Delaware Bay on the east and Chesapeake Bay on the west has a decided modifying effect upon the climate. Injurious early fall frosts are practically unknown, while it is seldom that late spring frosts are limiting factors in crop-production. The rainfall is approximately 40 inches a year. The distribution of this rainfall varies from year to year, but it is not often that the state suffers from excessive droughts.

The leading horticultural crops are tomatoes, asparagus, apples, peaches, grapes, pears, strawberries, cantaloupes, watermelons, peas, sweet potatoes and white potatoes. There are many kinds of vegetables grown for the city markets, but the above-mentioned are the principal ones grown on a trucking scale.

Delaware was formerly noted for its peach-production, which industry began in 1832. The high-water mark in peach-production was probably reached in the late sixties and early seventies. With the advent of the yellows and other peach diseases, the industry began to decline and reached its lowest ebb about 1910. Since that time a new interest has been aroused, better methods of culture are being practised and the business is rapidly centering into the hands of specialists. During 1914 and 1915, thousands of young peach orchards have been planted. Varieties have been standarized and most of the old-time favorites have disappeared. The principal varieties grown are Elberta, Belle of Georgia, Champion, Carman and Frances. The old-time varieties, such as Crawford's Late, Crawford's Early, Moore's Favorite, Reeves Favorite, Old Mixon, Stump, Mountain Rose and Smock have disappeared from the commercial orchards. In the future horticulture of the state, the peach is destined to play an important part.



2508. Delaware, showing the three counties.

The apple is probably the leading tree-fruit of the state. The apple industry is largely centralized in the central part of the state; but practically one-half of the farming area of Delaware is suitable for apple-culture. The industry began in central Kent County only a comparatively few years ago and it was not until about 1900 that the apple crop of the state began to attract attention. Delaware is especially suited to the production of certain varieties of winter apples of high quality and the growers are specializing in those varieties. Early apples do well and a large and profitable business is carried on in growing Yellow Transparent, Early Ripe and Williams. The apple is destined to be a close rival of the peach and probably in a few years will surpass the latter in production and value. Unlike the peach industry, the apple industry has been in the hands of specialists from the very beginning and to this fact can be accounted its steady growth. The farmyard apple orchard plays but little part in the economics of Delaware apple-production. The principal varieties of late apples are Jonathan, Stayman, Paragon (Arkansas), Winesap, York Imperial, Nero, Rome and Grimes. Of these varieties, the Stayman is especially adapted to Delaware conditions.

LXXII. North American horticulture.—Peach orchard in eastern Maryland.

The grape industry as a commercial proposition is comparatively new. Although grapes have been grown in the northern part of Kent County since 1855, it is only within the last decade that grape-culture has come to occupy an important place in Delaware horticulture. The industry is centralized in two rather distinct regions, the older one near Clayton and Smyrna and a newer and what will probably prove to be a more extensive one, near Dover. The grape industry only awaits the advent of the grape-juice factory to bring it to its proper place among the horticultural products of the state.

Pear-production is on the wane. There are large plantings of Kieffer in Kent and southern New Castle counties; but of late years the pear crop has not proved very profitable. The old orchards have suffered from the pear-blight, leaf-spot and psylla. There are but few new plantings of pears being made and present indications (1915) are that the next decade will witness the passing of the pear industry. The northern part of New Castle County is especially adapted to the growing of varieties like Lawrence, Seckel, Duchess and Anjou.

As the next decade will probably witness the passing of the Kieffer pear, the past decade (1905–1915) has witnessed the passing of the plum. From 1895 to 1900, there were large plantings of Japanese plums made in the state. In 1899 there were 32,000 trees, while at the present time the plum crop is comparatively unimportant and the farmyard tree controls the output.

The strawberry is the most important horticultural crop grown in the state. Its cultivation is largely localized in Sussex County. There are two great strawberry districts in this county, one at Bridgeville in the western part and the other at Selbyville in the southeastern part. In the Selbyville district especially, strawberry-growing is the principal farm industry. The acreage in this district is constantly increasing. The agriculture of the Bridgeville district is more diversified and the strawberry-production, while great, is not so large as it was about 1912. This district has recently become a large producer of cantaloupes. The principal varieties of strawberries grown in the state are Gandy, Chesapeake, Superior, Klondyke and Parsons.

The tomato is king among vegetables in Delaware. With the exception of a small area in the northern part of New Castle County, tomatoes are grown for canning purposes over the entire state. In 1914 there were 150 canneries in operation in the state, all but two of them specializing in canning tomatoes. The principal varieties grown for canning purposes are Greater Baltimore, Success, Stone, Red Rock and Paragon.

Since 1911, the growth of the sweet potato industry in the state has been phenomenal. At the present time (1915), the principal sweet potato region is in the western part of Sussex County from Seaford southward through Laurel to Delmar. Seaford, Laurel and Delmar are the great sweet potato shipping centers.

The leading horticultural regions of the state are Kent County for apples and grapes; Kent and Sussex counties for peaches; Sussex County for strawberries, cantaloupes, sweet potatoes and watermelons.

While the climate and soil of the state are well suited to the production of the English walnut and chestnuts, the industry has not been developed. The ravages of the chestnut blight have practically destroyed the chestnut orchards and it is doubtful whether any new plantings will be made. Black walnuts grow naturally over a large part of the state. There are no cultivated orchards of this nut. A few pecans are grown, but the success of growing this nut in Delaware as a commercial venture has not as yet been demonstrated.

The census figures of 1909 regarding the greenhouse interests are misleading, as they show the industry of growing plants and flowers to be of more importance than it really is. There are but few florists' establishments within the state.

The appreciation of fine landscape effects is steadily growing in the state. There are several large estates near Wilmington that have been well developed, such as the numerous Du Pont estates lying between Wilmington and the Pennsylvania line. The smaller towns and villages have been awakened to the need of parks and playgrounds and the next decade ought to witness a better appreciation of the beautiful in nature.

Practically few of the many varieties of fruit grown in Delaware have originated within her borders. Possibly the only variety of national fame that Delaware can lay claim to is the Reeves Favorite peach.

Among those men who have helped to form the horticulture of Delaware, may be mentioned Joseph Carter, of Smyrna, who may be called the father of the grape industry in Delaware, and J. G. Brown, of Wyoming, who had great influence in establishing apple-growing in the state.

Public-service agencies for horticulture.

The land-grant college of Delaware is Delaware College located at Newark. This college was established in 1833, but it was not until the passage of the Morrill Act in 1862 that any provision was made for teaching agriculture. The horticultural staff consists of two men who also devote their time to the work of the Experiment Station.

The Experiment Station is closely connected with the College. Aside from the land devoted to experimental growing of crops, the Station has forty concrete tree pits that are used for investigational work in the plant-food requirements of peaches.

There are no special horticultural schools in the state, but horticulture is taught as a part of the agricultural work in all the graded schools.

Extension work is carried on through the state by the College and also to some extent by the State Board of Agriculture.

The State Board of Agriculture controls the nursery inspection and all public matters concerned with the enforcement of horticultural laws.

Historically, geographically and horticulturally, Delaware is closely linked with the "Eastern Shore," of Maryland. This close community of interest of the two states has been recognized in the Penisular Horticultural Society, whose membership is drawn not only from Delaware and Maryland but also from the "Eastern Shore" counties of Virginia. The Society has ever played a most important part in horticultural development of the two states, Delaware and Maryland.

Statistics (Thirteenth Census).

The approximate land area, according to the Census report of 1910, is 1,257,600 acres, of which 1,038,666 were in farms, or 82.6 per cent of the land area. The acreage of improved land is 713,538; that of woodland, 252,032, and other unimproved land in farms, 73,296 acres. The total number of farms in Delaware in 1910 was 10,836, the average acreage of which was 95.9 acres. [The total area of Delaware is 2,370 square miles.]

The leading agricultural crops are cereals and hay and forage. The land occupied by cereals in 1909 was 43.3 per cent of improved land, or 309,288 acres, as compared with the acreage in 1899, when it was 318,772. The value of the products in 1909 was $4,692,329. The acreage of hay and forage in 1909 was 80,669, as compared with 74,800 in 1899, showing an increase of 7.8 per cent. The value of hay and forage in 1909 was $1,174,473. The forest products sold from the farms in 1909 amounted to $346,062 in value.

The horticultural crops grown are vegetables, small-fruits, fruits and nuts, and flowers and plants, and nursery products. In 1909, the total acreage of vegetables, including potatoes, was 37,871 and their value

$1,832,699, as compared with an acreage of 32,007 in 1899, valued at $1,144,221. The value of the fruits and nuts grown in 1909 was $240,704 as compared with $295,518 in 1899. The acreage of small-fruits in 1909 was 8,687, a decrease of 18 per cent from 1899, when the acreage was 10,599. The value of the small-fruits in 1909 was $649,732. Flowers and plants and nursery products in Delaware increased in acreage from 204 in 1899 to 226 in 1909, when the value of their products was $110,486.

Of the orchard-fruits in 1909, the apples produced more than one-half of the total production, and pears most of the remainder. The number of bearing apple trees in 1900 was 429,753; those not of bearing age, 263,813. The production in 1909 was 183,094 bushels, valued at $115,371. The pear trees of bearing age in 1910 were 449,692; those not of bearing age, 90,917. The production in 1909 was 105,357 bushels, valued at $52,022. The peach and nectarine trees of bearing age in 1910 were 1,177,402; those not of bearing age, 212,117. The production in 1909 was 16,722 bushels, valued at $21,402. Other of the orchard fruits, their production and value in 1909 were: cherries, 2,634 bushels, valued at $4,850; quinces, 806 bushels, valued at $1,572; plums and prunes, 657 acres, valued at $540.

The production of grapes was 1,938,267 pounds, valued at $43,967. The grape-vines of bearing age from 1,309 farms reporting, in 1910 numbered 260,963; those not of bearing age from 265 farms reporting numbered 98,950.

The production of nuts is an unimportant industry. The production of all nuts in 1909 was 39,142 pounds, valued at $964, of which 35,200 pounds were black walnuts, valued at $581.

Strawberries are by far the most important of the small-fruits raised in Delaware, with blackberries and dewberries ranking next. In 1899, the acreage of strawberries was 6,344; in 1909 this acreage had increased to 7,194 and the production was 12,730,265 quarts, valued at $569,354. In the period from 1899 to 1909, the acreage of blackberries and dewberries decreased from 2,935 to 1,256. The production in 1909 was 1,403,977 quarts, valued at $61,817. In 1909, there were also produced 275,871 quarts of raspberries and loganberries, valued at $17,359; 12,123 quarts of gooseberries, valued at $908; and 2,973 quarts of currants, valued at $294.

Of the vegetables produced, potatoes and sweet potatoes were the most important individual vegetables. In 1909, from a reported acreage of 9,703, there were harvested 880,360 bushels of potatoes, valued at $453,400. In the same year, the production of sweet potatoes and yams from 5,229 acres was 733,746 bushels, valued at $276,679. The value of tomatoes produced from an acreage of 13,108, in 1909, was $583,639. Other vegetables produced in Delaware, their acreage, and the value of the products in 1909, follow: asparagus, 410 acres, value of product $39,097; cantaloupes and muskmelons, 1,163 acres, value of product $52,228; celery, 44 acres, value of product $12,394; sweet corn, 1,341 acres, value of product $35,073; green peas, 1,234 acres, value of product $42,780; watermelons, 859 acres, value of the product $26,343.

The growing of flowers and plants is quite an important industry in Delaware. In 1909, the value of the production from 44 acres was $71,429. The area covered by glass in 1909 was 244,827 square feet, of which 233,087 were covered by greenhouses and 11,740 by sashes and frames.

Concerning nursery products, the acreage increased 4.6 per cent from 1899 to 1909 or from 174 acres to 182 acres. The increase in the value of the nursery products for the same period increased 126.5 per cent, the value being given as $17,241 in 1899 and $39,057 in 1909.

C. A. McCue.

Maryland.

Maryland (Fig. 2509) consists naturally of three distinct regions known as: (1) the coastal plain; (2) the Piedmont region, or plateau; (3) the Appalachian region. The coastal plain rests on both shores of the Chesapeake Bay. The portion lying between the Bay and the ocean is known as the Eastern Shore. It is generally level, of low elevation and deeply indented with bays and estuaries. This portion west of the Bay becomes hilly as it recedes from the shore and approaches the Piedmont plateau. Its western boundary is approximately indicated by the Potomac River to Washington, and the Baltimore and Ohio Railroad as it passes from Washington through Baltimore to Wilmington.

The Piedmont plateau extends westward from the coastal plain to the base of the Catoctin Mountains in Frederick County. It is traversed by several ranges of hills. Some of these are of considerable height.

The Appalachian region forms the western part of Maryland and may be divided into three districts. The first or eastern part commences at the foot of the Catoctin Mountains. It is traversed by a number of ranges forming the Great Valley and the famous Middletown Valley noted for its beautiful landscape, fertile soil, and prosperous farms. The central district of this region is bounded on the east by North Mountain, and on the west by Willis Mountain near Cumberland. It is traversed by various intermediate ridges and comprises the greater part of Washington and Allegany counties. It is upon the slopes of these mountains that the largest and most extensive commercial orchards of the state are found. The western district contains the Allegany plateau and extends to the western boundary of the state. It contains a portion of Allegany County and all of Garrett County. It contains the great divide, from which the water runs partly to the Atlantic by way of the Potomac and partly to the Gulf of Mexico by way of the Monongahela, Ohio, and Mississippi.

The climate of Maryland varies in the different physical regions just described. Over the coastal plain the winters are short and mild. The snowfall is light and of short duration. The region is noted for its long growing season. In the Piedmont region the summers are cooler and the winters more severe, though severe weather seldom begins before January. In the Appalachian region the climate is more severe than in the other regions. The winters set in earlier and the snowfall is generally heavy.

The mean temperatures during January and June for the various sections are as follows: coastal plain, 35° and 73.5°; northern central, 30.7° and 72.8°; western Maryland, 30.5° and 70.3°; all Maryland, 32.8° and 72.5°.

Occasionally greater extremes are encountered than these figures would indicate. Sometimes the mercury goes to 98° or 100° in summer, and in winter a cold wave may cause it to drop below zero, but these extremes are of short duration.

Along the Atlantic coast and the shores of Chesapeake Bay, frosts do not occur between about April 5 and November 10, giving a period of safe plant growth of about 210 days. The length of this period decreases rapidly as the distance from the shore increases. In the central parts of the "peninsula" of the Eastern Shore, frosts do not disappear until about April 15, and reappear about October 22, giving a safe growth period of 190 days. On the western or windward side of the Blue Ridge Mountains, the frost-period extends into the first week of May and reappears in the fall about the first week in October, giving a safe growth period of about 160 days.

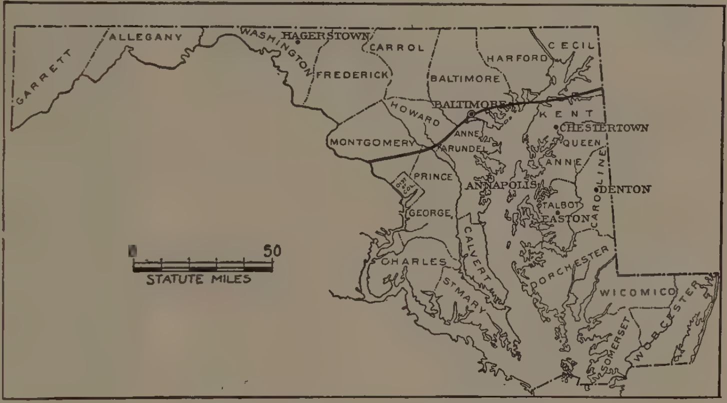
In Garrett County, forming the western part of the Appalachian region lying at 2,500 to 3,000 feet above sea-level, there is a marked shortening of the growth-period. Here injurious frosts extend into the early days of June and again set in about the middle of September. This gives only about 100 days of safe plant growth for the season in this region. Along the waters of Chesapeake Bay, in southern Maryland, the period of safe growth is more than again as long.

Over the coastal plain, the land is mostly light and largely dominated by the sassafras series of soils. The lighter of these soils are well adapted to early truck crops, while on their heavier sandy and gravelly loams peaches and apples thrive. In the northern tier of counties the soils are heavier and the agricultural interests are more diversified. The mountain slopes are well adapted to fruit-growing.

The transportation facilities, both land and water, are unsurpassed. Chesapeake Bay, with its numerous long, broad, navigable tributaries ramifying all parts of the state, gives Maryland a water-frontage larger that that of any other equal area. A large fleet of vessels is kept busy carrying produce from bay and river ports to Baltimore, Philadelphia, Washington, and other markets. Maryland is well supplied with railroads. Six distinct lines enter Baltimore. There are also a number of electric lines that carry freight. The Maryland State Roads Commission maintains an excellent system of state roads.

Climate, soil, transportation facilities with large markets near at hand, combine most efficiently to make Maryland a great horticultural region. Although small in area, it enjoys a remarkable range of soil and climatic conditions and because of this great range all of the horticultural products of the eastern United States can be grown with ease. In the entire region south of Baltimore, the growing of vegetables has assumed large proportions. The tomato is the most extensively grown vegetable crop of the state. In the production of tomatoes Maryland leads all other states. Potatoes, sweet corn, sweet potatoes, peas, cantaloupes, cabbage, beans and watermelons follow in the order named. Baltimore County leads in the production of early potatoes. Recently a rapidly increasing late potato area has developed in the higher altitudes of Garrett and Allegany counties. This region produces an excellent "seed" potato which has been found fully equal to the Maine-grown seed potatoes. These potatoes are now displacing the Maine-grown potatoes for planting purposes in the warmer regions of the state. Most of the sweet potatoes are grown on the light, warm, sandy soils of Anne Arundel County, although they are grown to some extent in every county of the state. Maryland ranks third in the Union in the production of spinach, green peas, and sweet corn, and sixth in the production of green beans and cantaloupes.

Strawberries stand out conspicuously among the small-fruit productions of Maryland. In the production of strawberries Maryland outranks every state in the Union, producing in 1909 nearly 30 per cent of all the strawberries grown in the United States. Strawberries thrive over the entire state but are most extensively grown in Anne Arundel, Wicomico, Somerset, Worcester and Caroline counties. In these counties, strawberries are produced in enormous quantities and during the picking season, which begins about May 12, special trains from these regions carry Maryland strawberries as far west as Chicago, and as far north as Montreal and Quebec. Anne Arundel also led in the production of blackberries and dewberries in 1909, but of late years the production of bush-fruits has been greatly on the increase in Washington and Allegany counties.



2509. Maryland, with the line of demarcation.

Maryland has long been famous as a peach-producing region. The first commercial orchard in the state was planted in 1800, in Anne Arundel County, 20 miles from Baltimore. The orchard was owned by Thomas Robinson. It contained 20,000 trees, and proved highly profitable. Other orchards soon followed; and soon peaches were grown on a large scale in Anne Arundel County. It is not known just when the first orchard was planted on the Eastern Shore. In 1830, a Major Philip Reybold planted an orchard of 6,000 trees in Kent County, and in the same year a Mr. Cassady planted 50,000 trees along the Sassafras River in Cecil County. Under the influence of the congenial soil and climate, with practically no enemies to contend with, the industry flourished and by 1865 the water fronts of Cecil, Kent, and Queen Anne counties presented the appearance of a continuous peach forest, extending inward for several miles. The peach industry of western Maryland is of comparatively recent origin. John A. Nicodemus planted the first orchard at Edgemont, in Washington County, and his orchard became the cradle of the industry in which many beginners received their first lessons in peach-growing. W. D. Hues also planted an orchard of 300 trees on the Blue Ridge Mountains, near Keedysville, in 1880. Keedysville is now a large shipping point for peaches. The first orchards were planted on the Blue Ridge; gradually they spread to lower levels and other ridges. The higher elevations, however, are considered the more desirable, as on the lower levels the crop is more frequently ruined by frosts.

This is a brief outline of the beginning of the peach industry in Maryland. For many years it dominated the fruit industry of the state. The comparative ease with which peaches were grown led many ambitious growers to plant larger areas than they could properly manage, and with the advent of the San José scale and the yellows, peach-curl borers, and other pests, many growers were forced to curtail their operations. This was more noticeable on the Eastern Shore than in western Maryland, where the plantings were more conservative and the orchards, on the whole, better managed. On the Eastern Shore, peaches were largely superseded by vegetable crops. At first, the cause of failure was attributed to a change in climatic conditions. This, however, is not the case, for under proper management and scientific methods peaches can now be grown on the Eastern Shore as well as formerly. Through the activities of the State Horticultural Department, in connection with the State Agricultural College, the growers have learned to overcome the inroads of scale, yellows, brown-rot, and other pests; and, since 1900, the planting out of peach, as well as other fruit-trees, has been on the increase. The following are among the leading commercial varieties grown: Greensboro, Carman, Mountain Rose, Champion, Elberta, Belle of Georgia, Heath Free, Reeves, Oldmixon, Chairs, Fox Seedling, Pickett Late, Stevens, Salway and Bilyeu.

The natural conditions for the production of apples are unsurpassed and the apple industry is growing steadily. On the Eastern Shore the early summer varieties thrive. Ripening as they do in June and early July, they bring high prices in the northern markets. The northern tier of counties have soil and climatic conditions favorable to the production of fall and winter varieties of the highest quality. Because of the great range of climate, a long list of varieties is available to select from. In western Maryland the best northern varieties like Spy, Tompkins King, Baldwin and Rhode Island Greening thrive on the higher elevations, while such excellent varieties as Grimes Golden, Jonathan, Winesap, Stayman Winesap, Paragon, Nero and Delicious can be grown to perfection in practically all parts of the state. At the present time the largest number of bearing trees are Ben Davis and York Imperial, but the planting out of these varieties has practically ceased. The present plantings are mostly Grimes, Jonathan Stayman, Winesap and Delicious. These varieties will soon be produced in large quantities. During the past ten years, large tracts of wild mountain land, considered worthless for agricultural purposes, have been converted into orchards. Some of these newly planted orchards are of considerable size. Near Cumberland on the Green Ridge Mountains and overlooking the Potomac River is probably located the largest single orchard project in the world. This project is converting 40,000 acres of wild mountain land into an apple orchard. Over 1,000,000 trees are already planted and the first plantings are now in bearing. This entire tract contains only three varieties, namely, Grimes, Jonathan, and Stayman Winesap. The largest full bearing apple orchard in the state is located near Hancock, in Washington County, and contains 900 acres. Orchards containing several hundred acres are common in this section. A large number of these newly planted apple orchards contain peaches as fillers.

Pears thrive throughout the state, and the planting of pear orchards has been on the increase. Kent and Anne Arundel counties lead in this industry.

Plums are grown only to a limited extent. They can be grown with ease but the other fruits are more profitable. Those grown are mostly of the Japanese and Wild Goose type. The production of sour cherries is on the increase.

In the production of grapes, Prince George's County leads. The production of grapes is steadily increasing throughout the state. Grapes ripen here at a time when the southern-grown grapes are off the market and before the northern grapes come on. The leading commercial varieties grown are: Moore Early, Concord, Niagara and Delaware. Besides these, Campbell Early, Lutie, Worden, Woodruff Red and Catawba are also grown in appreciable quantities.

The large fruit and vegetable industries have given rise to another large industry, namely, canning and preserving. According to the Twelfth Census, there were 468 such establishments, in 1909, turning out a product valued at $13,709,449. Of this amount, $12,538,862 was vegetables and fruits. Several of the larger plants continue to operate as fish and oyster canneries when the fruit and vegetable season is over. In canning, Maryland leads the other states. The tomato is the chief item. According to statistics compiled by the National Canners' Association, Maryland canned 41.6 per cent of all the tomatoes canned in the United States from 1908 to 1914.

The long growing season and the deep mellow soils make Maryland well adapted to production of nursery products. In 1914 there were fifty-two such establishments inspected by the State Horticultural Department. Most of these are small and are operated in connection with other farming operations. The number fluctuates from year to year. Some farmers grow a nursery crop only occasionally. The largest nursery in the state is located near Berlin, in Worcester County, and covers a tract of 2,500 acres devoted chiefly to the production of nursery products, fruit trees being the chief output. The second largest nursery is located near Baltimore and contains 1,200 acres.

Maryland abounds in beautiful scenery. The vicinity of Baltimore is surrounded by charming suburbs, beautifully landscaped and planted with trees, shrubs and flowers. Druid Hill Park, laid out by the Olmsted brothers, is one of the finest parks in the United States. The Green Spring Valley, north of Baltimore, is noted for its magnificent country homes and large estates.

One of the most influential horticulturists of Maryland was J. W. Kerr, a sketch of whose life will be found in volume III, page 1582.

Public-service agencies for horticulture.

The Maryland Agricultural College was established as a private institution in 1856, and opened for instruction in 1859. After Congress passed the Land-Grant Act in 1862 the General Assembly of Maryland formally accepted the grant and the Maryland Agricultural College was named as beneficiary. This made the College in part a state institution, and in the fall of 1914 it was entirely taken over by the state. The Agricultural College and Experiment Station are located at College Park. There are ten men on the staff of the College and Experiment Station devoting themselves to horticultural work.

Maryland has two horticultural societies; namely, the Peninsula Horticultural Society, founded in 1886, and the Maryland State Horticultural Society, founded in 1898. The object of both these societies is the promotion of horticulture in all its branches. Both societies receive some state aid. The Peninsula Society is primarily intended for residents of Delaware and the Eastern Shore of Maryland.

Statistics (Thirteenth Census).

The approximate land area of Maryland in 1910 was 6,362,240 acres. The land in farms numbered 5,057,140 acres, which was 79.5 per cent of the land area. Of the land in farms, 3,354,767 acres were improved; 1,467,333 acres were in woodland; and 235,040 acres was other unimproved land in farms. The number of all the farms in 1910 was 48,923. The average acreage to a farm was 103.4. [The total area is 12,327 square miles.]

The leading agricultural crops of Maryland are cereals, hay and forage, forest products of the farms and tobacco. The acreage of cereals in 1909 was 1,329,201, and the value of the products $21,908,730, which was 49.9 per cent of the total value of all crops. The acreage of hay and forage increased from 374,848 in 1899 to 398,842 in 1909, when the products were valued at $6,011,749, which was 13.7 per cent of the total value of all crops. The value of the forest products of the farms increased from $1,170,362 in 1899 to $2,349,045 in 1909. The acreage of tobacco in 1909 was 26,072, and the value of the production, $1,457,112.

Horticultural crops grown in Maryland are fruits and nuts, small-fruits, flowers and plants and nursery products, and vegetables. The value of the fruits and nuts produced in 1909 was $1,577,978, as compared with $1,311,386 in 1899. Small-fruits decreased in acreage from 17,522 in 1899 to 16,595 in 1909, when the value of the products was $1,227,548. In 1909 the total acreage of potatoes and other vegetables was 155,339, and their value $7,996,105. In 1899 the acreage was 133,344. Flowers and plants and nursery products increased in acreage from 1,449 in 1899 to 4,718 in 1909, an increase of 225.6 per cent, when the value was $1,053,901.

The total quantity of orchard fruits produced in 1909 was 2,577,359 bushels, valued at $1,517,400. Apples contributed nearly three-fourths of this quantity and pears, and peaches and nectarines most of the remainder. The apple trees of bearing age in 1910 numbered 1,288,482; those not of bearing age, 660,685. The apple-production in 1909 was 1,822,824 bushels, valued at $902,077. The peach and nectarine trees of bearing age in 1910 numbered 1,497,724; those not of bearing age 805,063. The production in 1909 was 324,609 bushels, valued at $361,617. Pear trees of bearing age in 1910 numbered 540,583; those not of bearing age 138,152. The production in 1909 was 367,359 bushels, valued at $168,561. In addition, there were produced in 1909, 42,315 bushels of cherries, valued at $60,121; 13,526 bushels of plums and prunes, valued at $16,192; 6,359 bushels of quinces, valued at $8,383; and 365 bushels of apricots, valued at $448.

The production of grapes is not of marked importance. In 1910 the grape-vines of bearing age numbered 138,801; those not of bearing age 44,690. The production in 1909 was 2,152,382 pounds, valued at $53,498.

The total production of nuts in 1909 was 318,148 pounds, valued at $5,687. Black walnuts and chestnuts contributed the greater part of this amount, the production of black walnuts in 1909 being 274,936 pounds, valued at $2,997; that of chestnuts, 24,842 pounds, valued at $1,439. There were also produced in 1909, 6,916 pounds of Persian or English walnuts, valued at $745; and 1,717 pounds of pecans, valued at $85.

Strawberries are the most important of the small-fruits, with blackberries and dewberries next in importance. The acreage of strawberries increased from 13,980 in 1899 to 14,292 in 1909, when the production was 23,611,095 quarts, valued at $1,070,072. In the same period the acreage of blackberries and dewberries decreased from 1,501 in 1899 to 1,180 in 1909, when the production was 1,372,164 quarts, valued at $68,817. The acreage of raspberries and loganberries decreased from 1,385 in 1899 to 846 in 1909 when the production was 959,369 quarts, valued at $67,516. There were also produced in 1909, 300,321 quarts of gooseberries, valued at $18,000; and 34,009 quarts of currants, valued at $3,138.

The tomato holds first place among the vegetables grown in Maryland. In 1909, it covered an area of 42,721 acres, and was valued at $2,037,634. Potatoes, sweet potatoes and yams are next in importance. The acreage of potatoes increased from 26,472 in 1899 to 39,299 in 1909, when the production was 3,444,311 bushels, valued at $1,782,954. The acreage of sweet potatoes and yams increased from 6,469 in 1899 to 7,956 in 1909, when the production was 1,065,956 bushels, valued at $483,751. Of the other vegetables produced in 1909, the more important were: 18,387 acres of sweet corn, valued at $386,277; 3,481 acres of cabbage, valued at $304,394; 3,516 acres of cantaloupes and muskmelons, valued at $246,333; 6,030 acres of green peas, valued at 220,709; 2,746 acres of green beans, valued at $153,013; 2,432 acres of watermelons, valued at $94,737; and 1,314 acres of spinach, valued at $80,653. Vegetables of lesser importance were asparagus, beets, cauliflower, celery, cucumbers, eggplant, horse-radish, kale, lettuce, onions, parsnips, radishes, rhubarb and turnips.

The acreage devoted to the production of flowers and plants increased from 174 in 1899 to 478 in 1909, an increase of 174.7 per cent. The total area of land under glass in 1909 was 2,175,584 square feet, of which 2,051,068 were covered by greenhouses, and 124,516 by sashes and frames. The value of the flowers and plants produced in 1909 was $597,001, as compared with $355,862 in 1899.

The acreage of nursery products increased from 1,275 in 1899 to 4,240 in 1909, an increase of 232.5 per cent. In 1909 the value of the nursery products was $456,900, as compared with $123,474 in 1899.

HERMAN BECKENSTRATER.

Virginia.

The state of Virginia (Fig. 2510) comprises six main physical or natural divisions known as the Tidewater, Middle, Piedmont, Blue Ridge, Valley and Appalachian regions. Each of these divisions has its own soil types and to a less extent its peculiarities of climate. These divisions consist of parallel belts of territory of the same general direction as the Alleghany Mountains.

The Tidewater division extends from the seashore to the head of tide and comprises about 11,350 square miles of territory. The highest elevation within this division is not more than 200 feet above sea-level. This district is traversed by numerous navigable rivers and its shores are indented by many estuaries and bays. The soil in this section is mostly drift from the more elevated part of the state and is usually light and easy to work. The climate is mild and somewhat more equable than the more inland sections of the state. The cheap transportation facilities furnished by the navigable waters, together with the mild climate and light soil of this section, has led to the development of truck-farming on an extensive scale. This constitutes the chief agricultural industry of the division. Parts of the three great truck regions of the Atlantic seaboard lie within this division of the state, namely, the Norfolk, Baltimore and Peninsula districts.

Middle Virginia is geologically the oldest region of the state and comprises 12,470 square miles of territory. It is, on the whole, more elevated than Tidewater but seldom exceeds an elevation of more than 500 feet. Horticultural crops are not extensively grown. Tobacco is the main crop, while corn and wheat succeed on the best types of soil. Bush-fruits do well in many parts of this district, while sections favored by good soil and proper elevation will produce good tree-fruits.

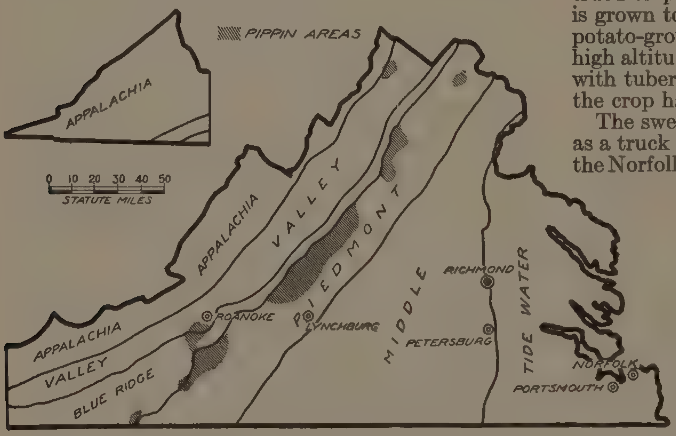
The Piedmont division of Virginia lies at the foot of the Blue Ridge and consists of a long, narrow belt of land varying in width from 30 to 40 miles and extending from the northern to the southern boundary of the state. It comprises 8,680 square miles of territory. The major part of this division varies in elevation from 500 to 1,000 feet above sea-level, although some of the detached mountain spurs lying within this district are much higher. The soils of Piedmont are highly variable but on the whole are well adapted to fruit-growing and grain-farming, while in the northern part of Piedmont, grazing is made possible by the presence of limestone soils and the natural growth of blue-grass.

The Blue Ridge division comprises the narrow range of the Blue Ridge Mountains. This division has a total area of 1,230 square miles. The northern two-thirds is rough and precipitous except in the mountain passes or gaps. The southern part, however, consists of a broad elevated tableland and includes the counties of Floyd, Carroll and Grayson. The soil of this part of the Blue Ridge section is not very different from that of Piedmont. Fruit-growing throughout the northern part of this section is confined largely to the mountain gaps and is of the same general character as that of Piedmont. Fruit-growing has not been extensively developed in the southern part of this section, owing to lack of proper transportation facilities. When this difficulty is met, there is likely to be a development in growing winter apples on a large scale, because of its high elevation.

The Valley section of the state lies northwest of the Blue Ridge and comprises a total area of 7,530 square miles. This is the best grain-growing section of the state. However, certain soils in this section are particularly adapted to the growing of apples and other fruits, and the development of commercial orcharding has been on a rather large scale. Frederick County, in the northern part of this valley, grows more fruit than any other one county in the state. Good fruit-land is to be found throughout this great valley. This division is divided into five subdivisions or minor sections by cross spurs which extend from the Blue Ridge to the Alleghany Mountains. Each of these minor divisions has its own particular types of soil. That part of the valley where fruit-growing is most highly developed extends from Staunton to the Potomac River. The part of this section which is drained by the waters of the Roanoke River appears to be especially adapted to canning crops. Botetourt County is noted for this industry. In the southwest, on the elevated land which divides the Holstein River district from the New River district, one will find large areas devoted to the growth of cabbage. The soil and climate of this elevated part of the valley seems admirably adapted to the production of this crop. The Valley division, as a whole, promises important development in fruit-growing and other horticultural industries.

The section of the state known as Appalachia lies to the northwest of the Valley and comprises a total area of about 5,700 square miles, consisting of large mountain ranges and narrow deep valleys. This part of the state is generally regarded as a grazing section, although there is much good apple and peach land to be found on the cross spurs and mountain slopes. Wherever good transportation facilities exist, profitable orchards are found. Much of this territory, however, remains undeveloped because of its inaccessibility.

The leading horticultural industries of the state are trucking and apple-growing. The Norfolk, Baltimore and Peninsula areas are especially adapted to the growth of truck crops and the development of trucking in this region has been on a large scale. Fruit-growing has been largely developed in the Piedmont, Blue Ridge and Valley sections of the state, while special phases of trucking have been developed in parts of the Valley section. Appalachia also offers good opportunities for fruit-growing, but the development of the industry there has not been rapid on account of the lack of good transportation facilities.



2510. Virginia, with the main geographical divisions.

The apple is the most important fruit crop of the state. Although this fruit has been grown commercially since colonial times, it is only in more recent years that the industry has assumed considerable proportions. Heavy plantings have been made during the last two decades and the annual yield of this crop is rapidly increasing. The apple succeeds on a commercial scale in the four western divisions of the state. Important apple-growing areas are to be found throughout Piedmont, while in many parts of the Valley and Appalachia it is extensively grown. The plantings in the eastern part of the state are primarily for home supply, but there is no reason why many localities in this part of Virginia cannot produce summer apples on a commercial scale. The leading varieties of commercial apples are York Imperial, Winesap, Ben Davis, Albemarle (Yellow Newtown), Arkansas, Grimes and Stayman Winesap.

The peach has long been regarded as an important fruit crop in Virginia, but it is only within recent years that its culture has assumed large proportions. At the present time the bulk of the peaches produced in this state is harvested from commercial plantings. The crop ripens in Virginia soon after the main crop of more southern districts is off the market, and is slightly ahead of the large orchards of West Virginia and Maryland. The peach grows to perfection throughout the state, wherever the frost factor can be safely ignored. The leading commercial varieties of this fruit are Carman, Hiley, Early Crawford, Elberta, Late Crawford, Smock, White Heath, and Bilyeu. The Elberta is planted more extensively than any other variety.

Other fruits, including the cherry, plum and grape, are important in certain restricted locations, but their cultivation is not general. Pear orchards have very generally proved unprofitable on account of the ravages of fire blight.

Small-fruits are grown in many parts of the state for local market, but their production with reference to northern markets is limited except in case of the strawberry, which is grown extensively in the trucking regions of the state and constitutes one of the most important sources of revenue.

Among the truck crops grown in the state, the potato sweet-potato and salad are the most important. The potato is grown almost entirely as a truck crop in Virginia, that is, early varieties are chiefly used and the crop is harvested before it is fully matured. Large areas in the Norfolk and Peninsular districts are utilized in the production of potatoes. The eastern part of the state is ideally adapted to the growth of this plant as a truck crop. In the western part of the state the potato is grown to some extent as a field crop, but this type of potato-growing is not extensive. A few localities with high altitude grow potatoes to supply the truck-farmers with tubers for seeding. When grown for this purpose the crop has generally proved rather profitable.

The sweet potato is next in importance to the potato as a truck crop. The great bulk of this crop is grown in the Norfolk and Peninsular areas. Sweet potatoes are not grown outside of Tidewater except in a small way for local market and for home use.

In addition to the crops mentioned above, other leading crops can be classed under one head as salads or pot-herbs. Spinach, kale, and lettuce are all grown on an extensive scale in the Norfolk district. Many growers confine their efforts largely to these crops. The profits are not great some years, but the grower who sticks to these crops year after year usually makes handsome profits in the long run.

Cabbage is another important truck crop of Virginia. It is grown for early market in the region around Norfolk, while it is grown very extensively for both early and winter markets in southwest Virginia. It constitutes the chief money crops in certain parts of Smyth and Wythe counties where it is grown on a large scale as a field crop.

The tomato is a very important crop in certain parts of the state. While it is grown extensively for general market in the principal trucking districts of the state, it is not a dominant crop in these sections. It becomes of primary importance in the canning districts, particularly in certain parts of Botetourt and Bedford counties, where the canning industry is firmly established.

In addition to trucking and apple-growing, which are the chief horticultural industries, grape-growing, small-fruit-culture and the nursery business have each received their share of attention. Grape-growing was once a thriving industry in the Charlottesville section of Piedmont but the industry has languished in recent years. It has been fully demonstrated, however, that the growing of table grapes is profitable in many parts of the state. There are several large nurseries and many small ones located in the state. Taken as a whole, the nursery business is of considerable importance. The state, also, has a number of large seed-houses and the growing of pedigreed seed is now important. The cut-flower industry has assumed considerable proportions near the large cities, while the same may be said for the forcing industry.

The development of fine country estates belongs chiefly to Colonial and ante-bellum days. However, many of these old estates have been preserved for the present generation, among which may be mentioned, Mount Vernon, Monticello and Montpelier. Throughout the state may be found less noted establishments which are, nevertheless, prized for their beauty.

The history of horticulture in Virginia is meagre. Beyond the fact that fruits and flowers have been prized from Colonial days, little is known of the evolution of the present horticultural industries. The strictly commercial phases of horticultural development are recent or are yet in their infancy.

Public-service agencies for horticulture.

The land-grant college of Virginia, known as the Virginia Polytechnic Institute, is located at Blacksburg in the southwestern part of the state. The State Experiment Station is a department of the College. The staff of the horticultural department consists of four horticulturists.

The inspection work for orchards and nurseries is administered by the Crop Pest Commission, which is directed by the same board as the Experiment Station. This office is essentially a department of the Agricultural College. Three trained officers devote practically their entire time to this work. There are also a large number of county inspectors engaged in orchard and nursery inspection under the direction of the Commission.

The Virginia State Horticultural Society is one of the influential agricultural associations of the state.

A Truck Experiment Station was organized in 1907 and located in the trucking district near Norfolk. This Station is supported and controlled conjointly by the United States Department of Agriculture, the Virginia Experiment Station, the State Department of Agriculture and the Southern Produce Exchange. Much valuable experimental and research work has already been carried out for the benefit of the trucking industry.

The State Department of Agriculture has its headquarters at Richmond, and devotes a considerable part of its efforts to the fruit-growing and trucking industries.

Statistics (Thirteenth Census).

The approximate land area of Virginia in 1910 was 25,767,680 acres. The land in farms was 75.7 per cent of the land area, or 19,495,636 acres. Of this land in farms, the improved land numbered 9,870,058 acres; the woodland, 8,414,680 acres; and other unimproved land in farms, 1,210,898 acres. The total number of farms in the state in 1910 was 184,018, and the average acreage to a farm, 105.9. [The total area of the state is 42,627 square miles.]

The leading agricultural crops of the state are cereals, tobacco, and hay and forage. The acreage devoted to the production of cereals decreased from 3,166,332 in 1899 to 2,841,114 in 1909, when the production was valued at $39,993,929, which was 39.8 per cent of the total value of all crops. Tobacco increased in acreage from 184,334 in 1899 to 185,427 in 1909, when the production was valued at $12,169,086. Hay and forage increased from 612,962 in 1899 to 773,577 in 1909, when the production was valued at $10,256,998. Forest products of the farms were valued at $10,118,851 in 1909, as compared with $3,797,116 in 1899.

Horticultural crops grown in Virginia are fruits and nuts, small-fruits, vegetables, including potatoes and sweet potatoes and yams, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $3,770,491, as compared with $2,755,487 in 1899. Small-fruits decreased in acreage from 8,796 in 1899 to 7,295 in 1909, when the production was 11,342,980 quarts, valued at $671,843. The total acreage of potatoes and other vegetables in 1909 was 252,119, and their value, $17,338,496. Excluding potatoes, and sweet potatoes and yams, the acreage of the other vegetables increased from 99,002 in 1899 to 124,354 in 1909, when the production was valued at $8,989,467. Peanuts increased in acreage from 116,914 in 1899 to 145,213 in 1909, when the production was 4,284,340 bushels, valued at $4,239,832. Flowers and plants and nursery products decreased in acreage from 1,343 in 1899 to 944 in 1909, when the production was valued at $522,480.

The total production of orchard-fruits in 1909 was 6,581,101 bushels, valued at $3,582,359. Apples contributed more than nine-tenths of this quantity, peaches and nectarines and cherries most of the remainder. The apple trees of bearing age in 1910 numbered 7,004,548; those not of bearing age, 3,435,591, and the production in 1909 was 6,103,941 bushels, valued at $3,129,832. Peach and nectarine trees of bearing age in 1910 numbered 1,585,505; those not of bearing age, 780,551. The production of peaches and nectarines in 1909 was 243,446 bushels, valued at $227,141. Cherry trees of bearing age in 1910 numbered 352,783; those not of bearing age, 83,323. The production in 1909 was 132,671 bushels of cherries, valued at $134,428. The production of other orchard-fruits in 1909 was: 74,486 bushels of pears, valued at $63,424; 22,597 bushels of plums and prunes, valued at $22,772; 3,443 bushels of quinces, valued at $4,037; and 515 bushels of apricots, valued at $723.

The production of grapes in 1909 was 4,108,694 pounds, as compared with 3,608,903 pounds, the production in 1899. The value of the grapes produced in 1909 was $156,266. The vines of bearing age in 1910 numbered 424,701; those not of bearing age, 136,026.

The production of nuts was 841,572 pounds, valued at $22,161. The nuts produced in 1909 were: 600,141 pounds of black walnuts, valued at $9,723; 210,364 pounds of chestnuts, valued at $9,686; 10,568 pounds of pecans, valued at $1,356; and 22,512 pounds of Persian or English walnuts, valued at $1,231.

Figs were the only tropical fruit of importance in 1909, the production being 234,057 pounds, valued at $9,652.

Strawberries are the most important of the small-fruits, with blackberries and dewberries ranking second in quantity and third in value, while raspberries and loganberries are third in quantity, but second in value. The acreage of strawberries decreased from 7,821 in 1899 to 6,606 in 1909, when the production was 10,761,381 quarts, valued at $626,649. Blackberries and dewberries decreased in acreage from 444 in 1899 to 344 in 1909, when the production was 273,551 quarts, valued at $16,485. Raspberries and loganberries decreased in acreage from 365 in 1899 to 276 in 1909, when the production was 257,322 quarts, valued at $24,853. Other small-fruits were: 23,447 quarts of gooseberries, valued at $1,909; 18,112 quarts of cranberries, valued at $1,050; and 8,127 quarts of currants, valued at $791.

The potatoes and sweet potatoes and yams rank far ahead of the other vegetables in importance. Potatoes increased in acreage from 51,021 in 1899 to 86,927 in 1909, when the production was 8,770,778 bushels, valued at $5,667,557. Sweet potatoes and yams increased in acreage from 40,681 in 1899 to 40,838 in 1909, when the production was 5,270,202 bushels, valued at $2,681,472. Other vegetables of importance were: 11,965 acres of tomatoes, valued at $495,773; 3,058 acres of spinach, valued at $489,170; 8,680 acres of cabbage, valued at $487,334; 1,766 acres of cucumbers, valued at $177,254; 2,867 acres of green beans, valued at $167,199; 3,159 acres of watermelons, valued at $136,898; 1,013 acres of kale, valued at $115,658; 969 acres of cantaloupes and muskmelons, valued at $83,148; 2,101 acres of sweet corn, valued at $73,050; and 787 acres of onions, valued at $59,524. Vegetables, the value of which was between $10,000 and $50,000, are as follows: asparagus, $31,205, eggplant, $20,430; lettuce, $24,187; radishes, $19,842; and turnips, $22,582. Vegetables of less importance are beets, parsley, pumpkins, rhubarb, rutabagas, and squash.

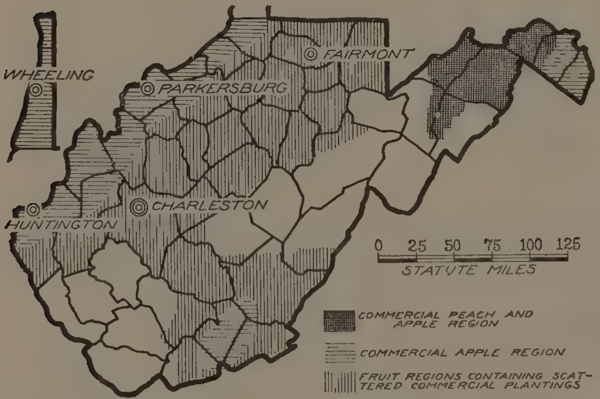
The acreage devoted to the production of flowers and plants increased from 143 in 1899 to 375 in 1909. The area under glass in 1909 was 1,413,170 square feet, of which 1,315,388 were covered by greenhouses, and 97,782 by sashes and frames. The value of the flowers and plants produced in 1909 was $362,488, as compared with $238,712 in 1899.

Nursery products decreased in acreage from 1,200 in 1899 to 569 in 1909, when the production was valued at $159,992, as compared with $214,988, the value in 1899.

H. L. Price.

West Virginia.

From a horticultural standpoint, West Virginia (Fig. 2511) presents many unique features and undeveloped possibilities. From the crest of the Alleghany Mountains to the waters of the Shenandoah River on the east and the Ohio River on the west, there is a difference in elevation of about 4,000 feet. The effect of this range in elevation is to furnish a climate with as much variation as might normally be found between Vermont and the Carolinas. As might be expected, the horticultural flora of the state is very extensive and the matter of varietal adaptation is one of great importance. The Baldwin and Northern Spy apples, when grown in Preston County at an elevation of 3,000 feet or more, are similar to the well-known New York and New England product, but when grown in the Shenandoah Valley they attain a very large size, ripen with the early fall varieties, are coarse in texture, poor in quality and can be kept only a few weeks even in storage.



2511. West Virginia, showing the regions of horticultural adaptabilities.

West Virginia has long been known as a producer of coal, oil, gas, and lumber, but in recent years the rapid development of the orchard industry has raised the state to a place of importance among the leading fruit-producing states. The Census report for 1910 indicated that West Virginia ranked twelfth among the states in the production of apples, and the government estimate for 1914 showed only seven other states exceeding West Virginia in the production of apples for that year. The peach industry is making similar gains, but is less extensive as a whole than the apple industry.

The horticultural industries of the state are unequally divided between fruit-growing and trucking, the former predominating. The leading fruits are the apple and peach, with the cherry forming a poor third. Pears, plums, grapes, and berries are grown in some sections to quite an extent, but the commercial plantings are somewhat scattered and the products are largely sold locally. The commercial apple districts are found in the eastern Panhandle, the northern Panhandle and along the Ohio River, and a small district is located near the southern boundary of the state. This does not mean that these are the only parts of the state producing apples, for scattering commercial orchards, many of them containing 100 acres or more, are found here and there in nearly every county. The peach industry, on the other hand, belongs to six counties of the eastern Panhandle, Hampshire, Mineral, Morgan, Berkeley, Hardie, and Grant. Outside of this region, with the exception of a few orchards along the Ohio River, the industry is purely local. The orchards of the state are all located upon rather rough mountain or hill land, with the exception of those in the Shenandoah Valley, where they are grown upon comparatively level or gently rolling limestone or shale soils.

The varieties of fruit vary somewhat with the section of state in which they are grown. In the Shenandoah Valley the York Imperial has long been the favorite. The "big, red, lopsided apple" finds a ready market in the southern and eastern cities and is also highly esteemed for export purposes. It sometimes scalds badly in storage, and more recent plantings have cut down the proportion of this variety. Next to the York Imperial rank the Ben Davis and its first cousin, the Gano, but these are planted in relatively small numbers at the present time. The Stayman Winesap, Arkansas (Mammoth Black Twig), Grimes, Winesap, Jonathan, Delicious, and Northwestern follow in about the order named. As one ascends the slope of the Alleghany Mountains, the Rome and Baldwin appear, while in the highest altitudes the Baldwin, Tompkins King, Rhode Island, Fallawater, and Northern Spy are found in abundance. Along the Ohio River and, in fact, over the entire western slope of the Alleghanies, the Rome finds a home perfectly adapted to its needs and consequently it is a ruling favorite in this whole region. Following the Rome, the other varieties are much the same as are found in the eastern Panhandle. Hancock County, at the northern extremity of the state, is peculiar in that it grows the Willow almost exclusively. This county early developed a system of common storage to which the long-keeping Willow was admirably adapted. The major part of the fruit from this county is placed in cellars, caves, and frame storage houses and is taken out in April and May in first-class condition for market. In the southern part of the state, the Stayman Winesap, Rome, York Imperial, Ben Davis, Grimes, and Jonathan are the best commercial varieties. In none of the regions are summer varieties grown extensively upon a commercial scale, although a few scattered plantings of Yellow Transparent may be found.

The peach industry is confined to a single section and embodies two very general soil types, chert and shale. The former is endowed with more abundant fertility and produces large, heavy-bearing trees. The shale soils require feeding but respond readily to applications of nitrate of soda or manure. The varieties are very much the same in all orchards and consist largely of the following: Carman, Champion, Belle, Elberta, Smock and Salway.

Peach- and apple-orcharding in West Virginia has developed along extensive rather than intensive lines. Individual growers frequently operate 200 to 300 acres.

while among the corporate holdings, orchards of 500, 600 and even of 1,000 acres may be found. These immense plants call for managerial ability of a high order and present problems involving finance, labor, culture, and marketing which are unknown to smaller growers. Thus far the labor problem has been met by utilizing the local population, but as more and more of the large orchards come into bearing it will be necessary to import many workers, particularly at harvest time. Inasmuch as the local labor is generally unskilled in harvesting and packing, it is the custom to employ experienced professional peach-packers who work northward after the crops are harvested in the more southern states. The barrel is the common package used for apples, but many growers are gradually introducing the box for such varieties as Grimes, Jonathan, Delicious, and Stayman Winesap. Early peaches, such as Carman, Champion, and Belle, are marketed in the Georgia carrier, while the Elberta, Smock, Salway, and other late sorts find a better sale in the Delaware sixteen-quart basket. There is also a tendency now to use the bushel basket for carefully graded late varieties. The methods of selling are unique in that there is a relatively small amount of fruit sold from the orchard or upon the tracks, the greater part being consigned to commission houses.

The trucking industry is at present confined to local areas along the Ohio and Big Kanawha rivers, to some of the "glade" lands on the higher elevations and to a small region in the eastern part of the state. The rich bottoms along the rivers furnish ideal locations for such an industry, while the numerous mining towns afford an almost unlimited market. It seems remarkable that with these advantages more persons have not taken up the work. The principal crops are early potatoes, watermelons, cantaloupes, tomatoes, cabbage, and sweet corn, while to a lesser extent are produced lettuce, spinach, kale, peppers, eggplant, onions, asparagus, and other vegetables usually found in this latitude. In Preston and other counties of a high altitude, where the "glade" lands are located, the midseason and late potatoes are grown. From these regions there has lately developed a promising trade in select seed-potatoes. Seed produced at an altitude of 2,500 or 3,000 feet has been found to equal and in some cases slightly excel the northern-grown seed in vigor and productiveness. This development is of special importance to the southern potato states which have been compelled to secure their seed from such distant points as Wisconsin, Michigan, New York, and Maine.

In the eastern Panhandle and principally in Morgan County, a tomato-growing and canning industry has developed. There are no canneries of great size but the work is done through a number of modest factories and private plants. Many of the orchardists make a practice of intercropping their young orchards for the first three years with tomatoes, thereby aiding materially in reducing the cost of bringing the orchard into bearing. Some of the orchard companies yearly plant from 50 to 100 acres of this crop and operate their own cannery.

As a specialized branch of horticultural industry, the nurseries about Point Pleasant and Mason should be mentioned. The rich loam of the second and third river-bottoms is well adapted to the production of young trees. The apple and peach are the principal fruits propagated, although the other fruits and some ornamentals are grown to a limited extent.

The commercial production of flowers is as yet practically undeveloped. The larger cities and towns are partially supplied by small local florists whose outfits are so small that frequent recourse must be had to outside sources to supply the trade. Coal and gas are plentiful and make a cheap fuel; markets are good and could easily be greatly extended; thus it would seem that a great opportunity is offered for extensive greenhouse development.

No account of West Virginia horticulture would be complete without some mention being made of the native fruits and nuts that abound in all parts of the state. Prominent among these is the native persimmon which may be found growing in all but the higher altitudes. This truly delicious fruit is held in high regard, but strange to say little or no attempt has been made to select and propagate the better strains, although the wild seedlings offer many promising variations. The same may be said of the pawpaw, clumps of which thickly dot the hillsides of the western and southern parts of the state. From early September until freezing weather begins, this aromatic fruit may be found bending the slender bush-like trees to the ground with the weight of its clusters of banana-shaped fruit. While the flavor of the pawpaw is not appreciated by all, it is nevertheless of some economic importance as evidenced by the fact that considerable quantities of the wild fruits are annually gathered and find a ready sale at about 50 cents a bushel. Huckleberries cover whole mountain sides and quickly take possession of forest clearings. Large quantities of this fruit, as well as the blackberry and dewberry, are picked and sold in the local markets. High in the mountain glades one is surprised to find the cranberry growing in abundance. One "cranberry glade" in Pocahontas County has 300 acres of this fruit. From one of the few "cultivated" bogs, fruit was sent to the St. Louis Exposition and won first honors. Thus far little or no attempt has been made to develop the industry. Among the nuts, may be found the chestnut, chinquapin, hickory, and black walnut. While all are relatively abundant, the chestnut is the only one of economic importance for its fruit. These nuts in some sections are gathered in great number and find a ready market. A few years ago several carloads would sometimes be shipped from one point, but now the demand for labor in other lines at that season of the year has cut down the harvest to only a vestige of its former importance.

In considering the men who were prominent in developing the horticultural interests of West Virginia, it is interesting to note that George Washington was one of the first if not the first fruit-grower of any consequence in the state. Records show that on March 18, 1774, he leased to one William Bartlett 125 acres of land "in the barens of Bullskin," a part of the present Berkely County. The guarantee was "to have and to hold for and during the lives of the said William Bartlett, Mary his wife, and Frederick their son, and the life of the longest liver of them." In addition to £6 annual rent it was agreed that Bartlett should leave a certain area of timber untouched, erect buildings, raise 10 acres of "English grass" and "that within seven years an orchard of one hundred winter apple trees at 40 feet distance every way from each other and that one hundred peach trees shall be planted on some convenient part of the said demised land and the same to be kept always during the continuance of said term, well pruned, fenced in and secured from horses, cattle and other creatures that may hurt, and if any of the said trees shall die, decay or be destroyed that others of the same kind shall be planted in their place, and the entire number thereof be kept up during the said term." Shortly after Washington's venture in the east came an important development in the Northern Panhandle. In 1786, Jacob Nessley purchased a tract of land bordering the Ohio River and cleared and planted 50 acres to apples and peaches. He grew seedling trees for the most part, although it is recorded that he had also some grafted stock. As his crop was devoted to the manufacture of fruit brandies, he was able to utilize the inferior seedlings to good advantage. As the direct result of his influence upon the locality, hundreds of acres of orchards have been planted and the Northern Panhandle grew famous for its production of winter apples. Long the foremost fruit region of West Virginia, it has only recently been surpassed by the still greater development in the Eastern Panhandle. As Jacob Nessley was the father of commercial fruit-growing in the Northern Panhandle, so was W. S. Miller in the Eastern Panhandle. In 1851, he planted 16 acres of apples, peaches and plums, and the close of the Civil War found him with 4,000 bearing peach trees upon his hands. As time went on the plantings increased until finally the aged pioneer had planted and matured upon his own farm over 4,000 apple and 25,000 peach trees, besides large numbers of plum, pear, quince and cherry trees.

Public-service agencies for horticulture.

The Land-Grant college of West Virginia is located at Morgantown. It was established in 1867 as "The Agricultural College of West Virginia." In 1868, however, this name was changed to "West Virginia University." The College of Agriculture was established in 1897. There are six members of the horticultural staff, who, together with one other man, also make up the horticultural staff of the Experiment Station.

The Experiment Station was established in 1887 at Morgantown as a part of the University.

There is a State Horticultural Society devoted to horticultural interests, with which are affiliated a number of county organizations.

Statistics (Thirteenth Census).

The approximate land area of West Virginia in 1910 was 15,374,080 acres. The land in farms was 65.2 per cent of this area, or 10,026,442 acres. Of this land in farms, the improved land numbered 5,521,757 acres; the woodland, 3,968,836 acres; and other unimproved land in farms, 535,849 acres. The total number of all the farms in 1910 was 96,685, and the average acreage to a farm, 103.7. [The total area of the state is 24,170 square miles.]

The leading agricultural crops are cereals, hay and forage, and tobacco. The acreage devoted to the production of cereals decreased from 1,307,428 in 1899 to 1,038,931 in 1909, when the production was valued at $15,997,700, or 39.6 per cent of the total value of all crops. Hay and forage increased in acreage from 601,935 in 1899 to 708,900 in 1909, when the production was valued at $7,492,747, or 18.6 per cent of the total value of all crops. Tobacco increased in acreage from 5,129 in 1899 to 17,928 in 1909, when the production was valued at $1,923,180. Forest products of the farms in 1909 were valued at $4,004,484, as compared with $2,632,980 in 1899.

Horticultural crops produced in West Virginia are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $3,149,122, as compared with $2,210,871 in 1899. Small-fruits increased in acreage from 1,994 in 1899 to 2,913 in 1909, when the production was 2,336,562 quarts, valued at $191,002. The total acreage of potatoes and other vegetables in 1909 was 88,224, valued at $6,968,618. Excluding potatoes, sweet potatoes and yams, other vegetables increased in acreage from 29,290 in 1899 to 43,524 in 1909, when the production was valued at $4,519,894. Flowers and plants and nursery products decreased in acreage from 586 in 1899 to 489 in 1909, when the production was valued at $157,645.

The total production of orchard-fruits in 1909 was 4,709,959 bushels, valued at $3,040,192. Apples contributed about nine-tenths of this quantity, and peaches and nectarines most of the remainder. Apple trees of bearing age in 1910 numbered 4,570,948; those not of bearing age, 2,772,025. The production of apples in 1909 was 4,225,163 bushels, valued at $2,461,074. Peach and nectarine trees of bearing age in 1910 numbered 1,424,582; those not of bearing age, 1,441,188. The production of peaches in 1909 was 328,901 bushels, valued at $368,584. Other orchard-fruits produced in 1909 were: 79,723 bushels of cherries, valued at $111,043; 32,948 bushels of plums and prunes, valued at $48,522; 29,916 bushels of pears, valued at $32,101; and 13,163 bushels of quinces, valued at $18,676.

The production of grapes in 1909 was 3,224,751 pounds, valued at $92,834. Grape-vines of bearing age in 1910 numbered 284,074; those not of bearing age, 76,465.

The total production of nuts in 1909 was 974,312 pounds, valued at $16,049. The more important of the nuts produced were: 878,215 pounds of black walnuts, valued at $11,430; 17,337 pounds of Persian or English walnuts, valued at $2,153; and 40,380 pounds of chestnuts, valued at $1,830.

Of the small-fruits grown in West Virginia, strawberries are the most important, the acreage decreasing, however, from 799 in 1899 to 709 in 1909, when the production was 812,049 quarts, valued at $74,778. Blackberries and dewberries increased in acreage from 367 in 1899 to 1,292 in 1909, when the production was 803,498 quarts, valued at $48,854. Raspberries and loganberries increased in acreage from 704 in 1899 to 847 in 1909, when the production was 648,174 quarts, valued at $60,749. Other small-fruits produced in 1909 were 34,009 quarts of currants, valued at $3,153, and 35,632 quarts of gooseberries, valued at $3,238.

The acreage devoted to the production of potatoes, the most important of the vegetables, increased from 30,123 in 1899 to 42,621 in 1909, when the production was 4,077,066 bushels, valued at $2,278,638. Sweet potatoes and yams decreased in acreage from 3,393 in 1899 to 2,079 in 1909, when the production was 215,582 bushels, valued at $170,086. The production of the more important of the other vegetables in 1909 was: 1,846 acres of tomatoes, valued at $87,386; 3,464 acres of green beans, valued at $60,156; 878 acres of sweet corn, valued at $37,449; 212 acres of cabbage, valued at $24,562; 473 acres of watermelons, valued at $21,059; 163 acres of turnips, valued at $4,809; 35 acres of onions, valued at $4,442; and 72 acres of green peas, valued at $2,053. Vegetables of less importance were asparagus, cantaloupes, celery, cucumbers, lettuce, and radishes.

The acreage devoted to the production of flowers and plants decreased from 39 in 1899 to 25 in 1909. The total area under glass in 1909 was 296,717 square feet, of which 272,182 were covered by greenhouses, and 24,535 by sashes and frames. The value of the flowers and plants produced in 1909 was $78,377, as compared with $44,384 in 1899.

Nursery products decreased in acreage from 547 in 1899 to 464 in 1909, when their value was $79,268, as compared with $61,700, in 1899. W. H. ALDERMAN.

North Carolina.

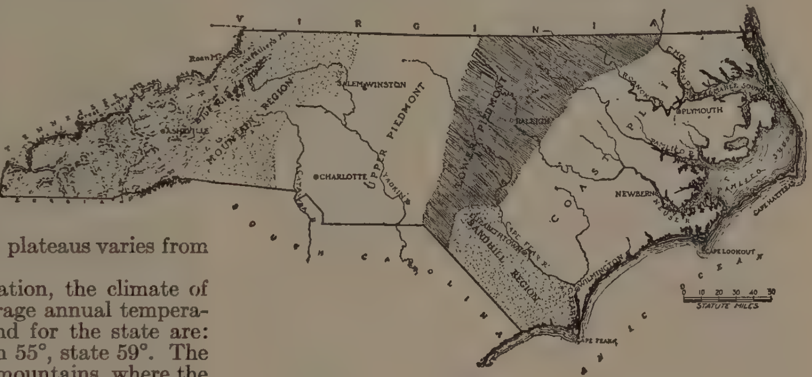
North Carolina (Fig. 2512) is a long, narrow strip of land in eastern United States, occupying a medial position between North and South. It extends 503 miles from east to west, with an average width of about 100 miles. Since the state extends from the surf of the ocean to the highest altitudes east of the Rocky Mountains, it has a very complex topography, a varying climate, a multiplicity of soil types and a consequent wide range of vegetable products.

North Carolina is divided into three parts, the Mountain region, the Piedmont and the Coastal Plain. The Coastal Plain begins at the Atlantic Ocean and extends inland a distance of about 150 miles. The land is extremely level, in most places not varying in elevation over a foot to the mile. Along the sounds and in the tide-water section there is from 4,000 to 5,000 square miles of swamp. A part of this area has been drained and is found to be extremely rich agricultural land.

About 100 square miles of the great Dismal Swamp lies within this state. Cleared parts of this region have become the richest agricultural and trucking land in the state. On its western border the coastal plain merges into the lower Piedmont region at an altitude of 150 to 200 feet.

The Piedmont region is a rolling hilly country comprising nearly one half of the state. It is gently undulating on its eastern border where it merges into the coastal plain, but assumes a bolder and more rugged aspect as it nears the Blue Ridge Mountains. It is the general farming section of the state.

The western, or mountain section of North Carolina is the most rugged and picturesque mountain region east of the Rockies. In this limited area all the ranges of the Appalachian system seem to have united and fused and then broken up in a confusion of lofty peaks with a labyrinth of intervening valleys. Within a range of 50 to 100 miles there are forty-three mountain peaks, 6,000 feet and upward in altitude. Several rivers which empty into the Atlantic Ocean or into the Gulf of Mexico find their sources in this high region. In all this maze of mountains, the Great Smokies form a continuous range on the west and make a natural border between North Carolina and Tennessee. The Blue Ridge with its subsidiary ranges and outlying spurs forms the eastern border of this region where it drops abruptly about 1,500 feet to the Piedmont plateau. These two general ranges are connected by many spurs and cross-ranges. The general altitude of the mountain valleys and elevated plateaus varies from 2,000 to 3,000 feet.



2512. North Carolina, showing the main divisions.

On account of its southern location, the climate of North Carolina is mild. The average annual temperatures for the different sections and for the state are: coast 61°, Piedmont 59°, mountain 55°, state 59°. The summers are warm, except in the mountains, where the altitude gives a cool climate like that of the northern states. Snow seldom falls and never lasts more than a few days. In the coastal section the winters are so mild that truck crops, such as spinach, kale, onions, cabbage, peas and lettuce are extensively grown in the open without protection during the winter season. The average annual precipitation for the state is 52 inches, for the coast 51, for the Piedmont 49, for the mountains 57. The rainfall is well distributed throughout the growing season, making irrigation unnecessary. The average length of the growing season as ascertained by the Weather Bureau records varies from 250 days near the coast to 200 in the central Piedmont and 180 to 190 in the mountains. In the coastal section, this long season permits the maturing of subtropical crops, such as cotton, peanuts and sweet potatoes, and gives the trucker a succession of two, three and even four crops a season.

The soils of the coastal region are of light sandy texture and are mostly underlaid with clay. They are classified by the Bureau of Soils as the Portsmouth, Norfolk and Orangeburg series. They vary from sand to sandy loam and fine sandy loam. These soils warm up quickly, are easy of cultivation and are therefore valuable for trucking purposes. In the swamp areas the soil is a rich black vegetable mold, varying from 2 to 6 feet in depth.

The Piedmont soils are of the Cecil clay series in which the clays predominate. Toward the east they are more or less blended with the sandy types of the coastal plain. The Piedmont clays are strong soils of friable texture and respond readily to cultivation. They are especially valuable for general farming and are capable of producing a wide variety of crops.

The mountain soils belong to the Porter and Toxaway series. The Toxaway soils which are of an alluvial nature are found in the valleys and bottom lands, while the Porter types are characteristic of the mountain slopes. In high mountain coves is found the Porter black loam, a soil much renowned for the production of fruit of the very finest quality.

On account of the wide range in altitude, the numerous soil types and the varied climatic conditions, the native flora of North Carolina is extremely rich and varied. Botanists from all over the world have studied the flora of this region, because within a few miles can be found the flora of the north overlapping with the subtropics, while the dense jungle of swamp and coastal vegetation lies within a day's travel of the alpine species of the mountains. In the southeast are found the palmetto, live-oak and cypress festooned with Spanish moss and intertwined with smilax and jessamine; a little farther up brings the long-leaf and numerous other species of pines, the gums and various species of oaks and hickories, while in the mountains are found huge timber trees of northern white pine, spruce, balsam and hemlock and dense thickets of laurel and rhododendron. A survey of the native fruit-bearing plants of the state shows eighteen families including thirty-nine genera and upwards of 330 species. The non-fruit-bearing plants and general flora run into great numbers of species.

The nurseries of the mountain region make a specialty of native ornamentals and alpine plants which are shipped in large quantities to all parts of the country. This region is one of the chief sources of supply for medicinal herbs which are gathered by the mountain people and shipped out in immense quantities by wholesale dealers of crude drugs. Cultivated ginseng is a considerable article of commerce. The great bulk of peach seed used by nurserymen all over the country is produced in this region.

The greatest horticultural industry in North Carolina is truck-growing. Its mild southern climate, light friable soils and accessibility to large markets makes eastern North Carolina an ideal section for trucking, especially during the winter and early spring months. In the market, North Carolina truck comes intermediate between Charleston and Norfolk. Early Irish potatoes make the largest tonnage, going north in early spring by boat and trainloads. The crop comes off the land sufficiently early to give place to corn, cotton and other farm crops. In the mountains the late varieties of potatoes are grown in considerable quantities, and marketed during the fall and winter. Early cabbages of the Wakefield type are extensively grown in the east in the winter and early spring and, like potatoes, are followed by a variety of truck or farm crops. The late, heavy types of cabbage are grown in summer in large quantities in the rich valley lands of the mountains. The sweet potato is grown in greater or less acreage on almost every farm in the state. The total of this production is a very large item amounting to about 8,000,000 bushels, one-seventh of the total crop of the United States.

Watermelons and cantaloupes are extensive truck crops in the sand-hill section of the state. The plantings of some of the larger growers run into hundreds of acres. In the shipping season, trainloads of refrigerator cars of melons and cantaloupes go north daily.

The growing of the head types of lettuce has become a considerable industry in North Carolina. The early crop is grown under cotton covers and the later ones in the open field. The lettuce crop is usually followed on the same land by radish, cucumbers or beets. Snap beans and English peas are much used as early spring catch-crops before the general summer farm crops. A considerable industry has developed in some localities in the production of very early corn for northern markets, before the northern crop comes in.

The strawberry is so extensively grown in North Carolina as to be considered a regular field crop. At Chadbourn, Mt. Tabor and other points along the Coast Line Railroad, the production of strawberries is so great that the large northern markets have found it to their advantage to send their agents to buy on the track as the cars are loaded. During the season, solid trainloads of iced cars of berries leave the strawberry section of North Carolina daily. The dewberry is also rapidly becoming a commercial fruit crop of importance, the output ranging in the neighborhood of 300 cars a season.

In the last decade, North Carolina has made rapid development in the commercial culture of apples. The high altitude combined with rich mountain soils and bright but cool climate make fruit of high color and a fine quality. Standard northern varieties are grown as well as many of southern origin. On many mountain slopes, owing to favorable air-drainage, thermal belts or zones are found where orchards have a high immunity to injury by cold. For this reason the commercial orchards are located mostly on the high sloping sides of the mountains. Commercial orchards vary in size from a few hundred up to as high as 50,000 trees. (See Volume I, page 322.)

The peach orchards of North Carolina are situated mostly in the sand-hill section, but there is a general exodus of peach-growing to the higher lands of the foothills and mountain spurs where thermal conditions give a greater exemption from frost. North Carolina peaches are of high color and excellent quality. They go to market about ten days later than the Georgia crop and nearly two weeks earlier than the northern peaches.

The grape in North Carolina is represented by two different types,—the muscadines, which are native of the coastal region, and the labruscas or "bunch grapes," which are grown mostly in the Piedmont and mountains. The Scuppernong, a white variety of the muscadine or rotundifolia type, is found as a domestic fruit on almost every plantation in eastern Carolina. Like the fig, it has proved to be almost an ideal home fruit for the South. It will stand almost any kind of neglect and almost unfailingly produces an abundant crop of very excellent fruit.

Some very large vineyards of Scuppernong grapes have been developed for wine purposes, but in the face of an increasing temperance sentiment the industry is not enlarging. At the horticultural branch experiment station, at Willard, an extensive experiment with muscadine grapes is being conducted by the State Department of Agriculture and Experiment Station in coöperation with the Division of Pomology of the National Department of Agriculture. The most promising varieties of the rotundifolia species from Virginia to Texas have been collected and are being tested. Breeding work is under way to develop varieties of this species that will be valuable for dessert and market purposes. When given careful tillage and an especially thorough spraying, the "bunch grapes" produce very fine fruit.

The "paper-shell" pecan is rapidly coming into prominence in eastern North Carolina as an orchard crop. Orchards of budded pecan trees of standard varieties are being planted every year and the earlier plantings are coming into bearing. Seedling groves are being top-worked to named varieties. In the Piedmont section, plantings are being made of English walnuts.

Public-service agencies for horticulture.

The Land-Grant college of North Carolina commonly known as the "College of Agriculture and Mechanic Arts," is located at West Raleigh. The institution was established in 1889. The teaching work in horticulture is carried on by one professor and one instructor.

The North Carolina Agricultural Experiment Station was established originally as a division of the State Department of Agriculture, in 1877. In 1887 the Station became a department of the College and was conducted jointly by the College and the Department of Agriculture from 1887 to 1907 with the exception of three years. The branch experiment stations, or test farms, are located so as to represent the major soil types, the climatic conditions and the principal agricultural and horticultural industries of the state. The Pender station is located at Willard, 33 miles north of Wilmington. It represents the great trucking industry of the state. The Edgecombe station, situated near Rocky Mount, is located to represent the northeastern coastal section and the soils of that region. The experiments are principally with corn, cotton and peanuts. The Iredell station, located at Statesville, represents the Cecil clay soil type and the crops of the Piedmont region. The Swannanoa station is located in the mountains near Asheville at an altitude of 2,200 feet. It represents the principal soil types and crops of the mountain region. The Transylvania station is located so as to represent the best conditions for commercial apple-culture. It has a wide range in altitude and soil conditions. The Granville station, located at Oxford in the old bright tobacco belt, has been equipped for experimental work in the culture and curing of tobacco. The Black Land station is located at Wenona and represents the muck soils of the swamp areas, of which there are between 2,500,000 and 3,000,000 acres in the state. There are five members of the horticultural staff of the Experiment Station. Forty-four bulletins on horticultural subjects have been issued.

There are no special schools in the state devoted to horticulture, but horticulture is taught in connection with agriculture at the new agricultural high-schools. Horticulture is not taught in the public schools, except occasionally in the form of nature-study or school-gardens.

North Carolina has a well-equipped State Department of Agriculture, divided into twelve divisions. The Department issues a monthly series of bulletins of which thirty-three have been on horticultural subjects.

The work done by the State Horticulturist in addition to that in connection with the Experiment Station and test farms is largely in the nature of extension or development work. A coöperative investigation was begun in 1912 with the National Weather Bureau to study the phenomena known as "thermal belts" or "frostless zones," found so commonly in the mountains of North Carolina. Observing stations have been located at different altitudes and on varying slopes and exposures at seventeen places in the mountains.

The newly organized Division of Markets is forming coöperative associations for the better distribution and marketing of fruits, vegetables and other products.

The inspection of nurseries for San José scale and other injurious pests is under the control of the Entomologist of the State Department of Agriculture.

Statistics (*Thirteenth Census*).

The land area of North Carolina in 1910 was approximately 31,193,600 acres. The land in farms was 71.9 per cent of the land area, or 22,439,129 acres. Of this land in farms, the improved land numbered 8,813,056 acres; the woodland 12,451,739 acres; and other unimproved land 1,174,334 acres. The total number of farms in the state in 1910 was 253,725, and the average acreage to the farm 88.4. [The total area is 52,426 square miles.]

The most important of the agricultural crops grown in North Carolina are cereals and cotton. The acreage of cereals decreased from 3,794,064 in 1899 to 3,250,870 in 1909, when the production was valued at $37,848,797, which was 26.5 per cent of the total value of all crops. Cotton, including cotton-seed, increased in acreage from 1,007,020 in 1899 to 1,274,404 in 1909, when the value of the production was $50,483,345. In the same year the production of tobacco from 221,890 acres was valued at $13,847,559. The value of the forest products of the farms in 1909 was $11,364,134, as compared with $4,915,991 in 1899.

Horticultural crops grown in North Carolina are fruits and nuts, small-fruits, potatoes, sweet potatoes and other vegetables, and flower and plants and nursery products. The value of the fruits and nuts produced in 1909 was $3,635,425, as compared with $1,470,735 in 1899. There was a decrease in the acreage of small-fruits from 6,837 in 1899 to 6,701 in 1909, when the production was 12,827,427 quarts, valued at $853,076. The acreage of potatoes and other vegetables increased from 156,947 in 1899 to 212,710 in 1909, when the production was valued at $12,585,018. Excluding potatoes, the acreage of other vegetables increased from 64,598 in 1899 to 95,980 in 1909, when the production was valued at $6,496,308. The acreage of flowers and plants and nursery products decreased from 1,210 in 1899 to 861 in 1909, when the production was valued at $393,963.

The total production of orchard-fruits in 1909 was 6,324,301 bushels, valued at $3,248,036. Apples produced about three-fourths of this quantity and peaches most of the remainder. The apple trees of bearing age in 1910 numbered 4,910,171; those not of bearing age, 1,835,337, and the production in 1909 was 4,775,693 bushels, valued at $2,014,670. Peach trees of bearing age in 1910 numbered 2,661,791; those not of bearing age 861,042, and the production in 1909 was 1,344,410 bushels, valued at $1,041,767. Other orchard-fruits produced in 1909 were: 84,019 bushels of pears, valued at $81,347; 61,406 bushels of plums and prunes, valued at $45,274; 53,788 bushels of cherries, valued at $60,453; 3,435 bushels of mulberries, valued at $3,065; 1,125 bushels of quinces, valued at $1,017; and 425 bushels of apricots, valued at $443.

The production of grapes in 1909 was 15,116,920 pounds, valued at $336,083. The grape-vines of bearing age in 1910 numbered 411,278; those not of bearing age, 120,208.

The production of nuts in 1909 was of comparatively little importance, there being only 1,244,629 pounds produced, valued at $28,535. While the black walnut is the most important nut, there being 1,081,480 pounds of them produced in 1909, valued at $16,138, as compared with 74,861 pounds of pecans, valued at $8,194; it is interesting to note that the pecan trees of bearing age in 1910 numbered 6,876 while those not of bearing age numbered 20,781. In 1909 there were also produced in North Carolina 73,303 pounds of Persian or English walnuts, valued at $3,686.

Tropical fruits are of little importance in North Carolina, the total value of those produced in 1909 being $22,771, of which $22,632 were contributed by 660,624 pounds of figs.

Strawberries are by far the most important of the small-fruits, with blackberries and dewberries ranking next. The acreage devoted to strawberries decreased from 5,616 in 1899 to 5,420 in 1909, when the production was 10,313,361 quarts, valued at $712,126. The acreage of blackberries and dewberries increased from 1,073 in 1899 to 1,233 in 1909, when the production was 2,464,065 quarts, valued at $136,609. Other small-fruits produced in 1909 were: 37,764 quarts of raspberries and loganberries, valued at $3,388; 5,831 quarts of gooseberries, valued at $536; 5,382 quarts of currants, valued at $400; and a small amount of cranberries.

The acreage devoted to the growth of the sweet potato increased from 68,730 in 1899 to 84,740 in 1909, when the production was 8,493,283 bushels, valued at $4,333,297. Potatoes increased in acreage from 23,619 in 1899 to 31,990 in 1900, when the production was 2,372,260 bushels, valued at $1,755,413. Peanuts formed a considerable industry in 1909, the acreage having increased from 95,856 in 1899 to 195,134 in 1909 when the production was 5,980,919 bushels, valued at $5,368,826. The production of the more important of the other vegetables was: 5,825 acres of watermelons, valued at $179,238; 2,256 acres of cantaloupes and muskmelons, valued at $163,902; 1,371 acres of cabbage, valued at $132,715; 2,387 acres of green beans, valued at $61,100; 835 acres of green peas, valued at $31,032; and 359 acres of tomatoes, valued at $22,562. Other vegetables produced were asparagus, beets, sweet corn, cucumbers, lettuce, onions, green peppers, and turnips.

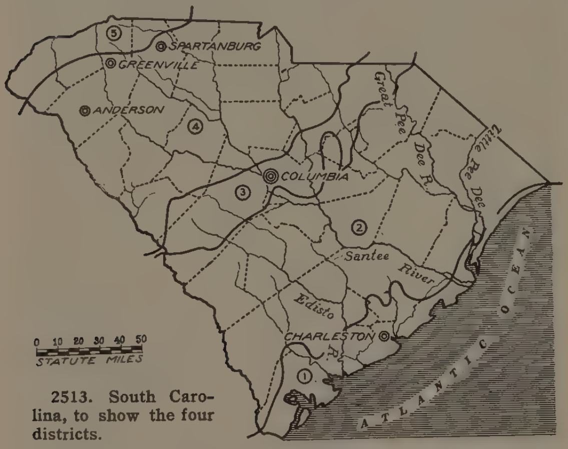
The acreage devoted to the production of flowers and plants, increased from 61 in 1899 to 107 in 1909. The total area under glass in 1909 was 193,139 square feet, of which 176,853 were covered by greenhouses, and 16,286 by sashes and frames. The value of the flowers and plants produced in 1909 was $126,995. The acreage devoted to nursery products, however, decreased from 1,149 in 1899 to 754 in 1909, when the value of the nursery products was $266,968. W. N. Hutt.

South Carolina.

South Carolina (Fig. 2513) ranks thirty-eighth in land area among the states and territories of continental United States. Rising from the sea-level to an altitude of 3,436 feet in the northwestern part of the state, and combining as it does different types of soil and conditions of climate, it possesses wonderful horticultural possibilities. The horticultural interests receiving greatest attention are trucking and fruit-growing, although the plant trade business and the production of cut-flowers is now coming into prominence. With its splendid water-power, numerous manufacturing centers have sprung up, and such communities offer good local markets for horticultural products.

Horticulturally, the state is divided into five regions, namely: the Coastal, Pine, Sand Hill, Piedmont and Mountain regions. The Coastal region, embracing in addition to the narrow strip along the coast a number of islands, has a remarkably mild climate which permits the growing of subtropical fruits, such as the fig and the more hardy citrous fruits. The fig, particularly, grows to perfection in this locality, and its production for preserving purposes is on the increase. Pecans and strawberries are also grown extensively here. The fine sandy loam soil, with the water-table only a few feet below the surface, furnishes ideal conditions for both these crops. There are individual growers that have hundreds of acres planted to pecans and about 1,000,000 quarts of strawberries are shipped annually from this region to northern markets. This region is especially adapted to commercial vegetable-growing. The products come in just after the Florida crops are off, which eliminates competition and gives the growers an open market. The principal vegetables grown are asparagus, beans, cabbage, cucumbers, lettuce, green peas and potatoes. The islands along the coast are famous for the production of cabbage plants. Four million or more packages of cabbage plants are shipped out from here annually to all parts of the United States.

The Pine Belt is primarily a farming section with large plantings of cotton, corn, oats and other general farm crops. The region is mostly flat with an average slope of 3½ feet to the mile in the southeastern part, where there are numerous fresh-water swamps, and a slope of about 5 feet to the mile in the northwestern part. It extends across the state parallel to the Coastal region, having a varying width from 50 to 80 miles. Although general farming interests are of chief importance in this region, there are a few horticultural crops that are proving remunerative. A considerable area is devoted to the growing of cantaloupes and watermelons, which are shipped to the northern markets. In some counties, asparagus is also grown as a commercial product. Rotundifolia grapes, Japanese persimmons and figs grow luxuriantly in this region, but they have received little attention in a commercial way.



2513. South Carolina, to show the four districts.

The Sand Hill region comprises an area of about 30 to 40 miles in width, stretching through the central part of the state from the Savannah River to the North Carolina line. Being for the most part a chain of hills with deep sandy soil, this region is remarkably well adapted to the growing of peaches, Labrusca grapes and dewberries. All of these fruits attain high quality and color here and ripen early. The Mayflower variety of peaches is ready for market by the last of May. The Delaware is the most largely grown of all the varieties of grapes because of its good shipping quality and splendid flavor, but the Brighton, Niagara, and Concord varieties are grown considerably for the local markets. Dewberries, ripening the earliest of all the berries, bring good prices on the local as well as more distant markets. The largest peach-growers of the state are in this region, individual growers in some cases having as many as 20,000 to 30,000 trees. A great many young orchards, varying in size from 100 to 5,000 trees, have recently been set. There are no commercial plum orchards in this region, although varieties of the Japanese and Wild Goose types of plums do well. This region is also well adapted to the growing of early vegetables, and market-gardening is being carried on rather extensively in areas adjacent to the larger towns.

The Piedmont region includes all of the northwestern portion of the state except parts of the counties of Oconee, Pickens, Greenville and Spartanburg, which lie in the extremely northwestern corner of the state and make up the mountain region. The elevation of the Piedmont region varies from 400 feet in the southeastern portion to 900 feet in the northwestern portion. There is magnificent water-power in the many streams which have been utilized in manufacturing interests, creating a large mill population and making a good field for the market-gardener. Probably the leading fruit of commercial importance in this section is the peach, which does well on the elevated areas. All the summer varieties of apples do well here and a few of the winter varieties, as the Winesap, Delicious, Yates, and Ben Davis, but there are few commercial plantings of importance. The canning industry has reached considerable proportions in this section, both fruit and vegetables being used in canning. The principal fruits that are canned are peaches, apples and blackberries, while the chief vegetables used are tomatoes, snap beans and corn.

The Mountain region occupies the northwestern corner of the state, including the greater part of Oconee, Pickens, Greenville and a small part of Spartanburg counties. The soil on the mountainsides is in most cases very fertile and the elevation is from 1,000 to nearly 3,500 feet, which makes this region particularly well adapted to the growing of those fruits that require a high altitude. Apples do especially well here, and almost all the leading commercial varieties are grown. They produce heavy crops, and in color, flavor, and keeping quality are not surpassed by the apples of any section in the eastern part of the United States. It has long been known that in this part of South Carolina excellent winter apples could be grown, but it is only during the past fifteen years that commercial apple-growing has come into prominence. There are now a large number of orchards containing from a few hundred to thousands of bearing trees. The varieties most largely planted are Stayman Winesap, Red Winesap, Rome Beauty, Virginia Beauty, Delicious, and Kinnard. The box is gradually replacing the barrel as a shipping package. A few years ago almost the entire bulk of the apple crop that was not sold on the local markets was marketed in barrels, but the growers being quick to observe the advantages of the small package have discarded the barrel and adopted the Standard apple-box. There are several box-making plants in the vicinity of the larger growers that have an output of more than a thousand boxes a day. In a few instances the growers own and operate their own box-making plants. The large amount of timber land in this region, with the splendid water-power, makes it possible to operate such plants at comparatively small cost. Aside from the commercial orchards now in bearing, there are a number of young orchards from one to five years old, and it will be only a short time before the face of these hitherto wooded hills will be covered by wealth-producing orchards. Other fruits that thrive in this region, but fail to do well in other sections of the state, are the sweet cherry, red raspberry, currant, and gooseberry. There are at present no commercial plants of importance of these fruits, although the home gardens produce them in abundance. Cabbages, onions, and potatoes are grown extensively in this region for the fall and winter trade. They are sold locally and to some extent shipped to the southern cities. The tomato is also grown extensively in some sections of the Mountain region for canning purposes. In a few instances large areas have been devoted to this crop for marketing in the Gulf States during the early fall. All vegetables and small-fruits may be grown successfully in this region.

It may be seen, therefore, that the horticultural products are extremely varied. From the seashore to the mountains, there are sections peculiarly adapted to particular horticultural interests; yet, taking the state as a whole, with the exception of the few subtropical fruits that do well in the Coastal region, all the principal fruits of the temperate zone may, if given proper care, be grown in every part of the state.

For instance, in the home orchards throughout the state may be found almost every manner of fruit. Also are found numerous fruits, such as the blackberry, dewberry, huckleberry, chickasaw and wild goose plums and the sour cherry growing luxuriantly in the wild state.

Among the former prominent horticulturists in South Carolina may be mentioned Meggot, a Huguenot, who is recorded as having obtained a grant of money from the legislature of South Carolina about the year 1800 for the development of the grape industry; Nicholas Herbemont, of Columbia, the originator of the Herbemont grape; J. F. C. DuPre, the first Professor of Horticulture of Clemson Agricultural College and the first Horticulturist of the South Carolina Experiment Station; James Stanley Newman, the first Professor of Agriculture of Clemson Agricultural College and also at one time prominent in horticultural affairs in Georgia and Alabama (see Volume III, page 1589).

Public-service agencies for horticulture.

In South Carolina the principal source of agricultural information is the Clemson Agricultural College, at Clemson College. This is the state's agricultural and mechanical institution. It was incorporated in 1889, but did not open until 1893. There are five on the horticultural staff at this time.

The South Carolina Experiment Station is a department of Clemson College. It is located at the college and there are two substations, one at Summerville, in the Coastal region, and one at Florence, in the Pee Dee region. The establishment of another substation in the Sand Hill region is contemplated. The station workers in horticulture are three in number. Fourteen bulletins on subjects related to horticulture have been published.

Some elementary instruction in horticulture is given at the Winthrop Normal and Industrial College (female), Rock Hill, and at the Colored Normal and Industrial Agricultural and Mechanical College, at Orangeburg. Among the public schools of the state there are about a hundred which are teaching agriculture under the direction of the extension division of Clemson College. In these schools horticultural instruction is given, and a considerable number of them have 1-acre orchard demonstration plots. The teaching of agriculture in the public schools of the state is spreading rapidly.

The extension division of Clemson College has two horticulturists working over the state throughout the year. The work has concerned itself largely with building up commercial orcharding in the state. The peach and the bunch grape are the fruits most generally grown on a commercial scale. Attention has been given to the question of marketing the fruit. Much has been done to encourage home orchards and in most of the counties there have been established model 1-acre demonstration orchards. There have been campaigns for the establishment of home gardens, especially fall and winter gardens. Canneries have been encouraged and the state is well up in the canning club work for girls. The extension division at Clemson College also employs an agent in marketing, who devotes part of his time to bettering market conditions for horticultural products.

A rigid inspection service is maintained by the State Crop Pest Commission, whose executive officers are the plant pathologist and entomologist of Clemson College. They inspect nursery stock and importations of nursery stock, and in other ways prevent the spread of noxious insects and diseases.

Statistics (*Thirteenth Census*).

The approximate land area of South Carolina was reported in 1910 as 19,516,800 acres. The land in farms as 69.2 per cent of the land area, or 13,512,028 acres. Of this land in farms, the improved land numbered 6,097,999 acres; the woodland, 6,339,142 acres; and the other unimproved land in farms, 1,074,887 acres. The number of all the farms of the state in 1910 was 176,434, and the average acreage to the farm was 76.6. [The total area is 30,989 square miles.]

The leading agricultural crops of the state are cotton, including cotton seed, and cereals. The acreage devoted to the production of cotton increased from 2,074,081 in 1899 to 2,556,467 in 1909, when the production was valued at $96,381,067, which was 67.9 per cent of the total value of all crops. The cereals decreased in acreage from 2,251,050 in 1899 to 1,955,695 in 1909, when the production was valued at $25,434,539. Hay and forage increased in acreage from 106,124 in 1899 to 209,767 in 1909, when the production was valued at $3,189,122. Tobacco increased in acreage from 25,993 in 1899 to 30,082 in 1909, when the production was valued at $2,123,576. The value of the forest products of the farms in 1909 was $4,153,092, as compared with $1,915,280 in 1899.

Horticultural crops produced are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts in 1909 was $1,121,662, as compared with $360,515 in 1899. Small-fruits increased in acreage from 591 in 1899 to 856 in 1909, when the production was 1,408,099 quarts, valued at $113,254. In 1909 the total acreage of potatoes and other vegetables was 109,482 and their value $6,922,021. Excluding potatoes, the acreage of the other vegetables increased from 40,771 in 1899 to 51,994 in 1909, when the production was valued at $3,705,991. Flowers and plants and nursery products decreased in acreage from 112 in 1899 to 44 in 1909, when the production was valued at $56,503.

The total production of orchard-fruits in 1909 was 1,132,668 bushels, valued at $956,376. Peaches and nectarines contributed more than half this quantity, and apples most of the remainder. The production of peaches and nectarines was 643,040 bushels, valued at $557,303. The number of trees of bearing age in 1910 was 1,336,142 and those not of bearing age, 349,790. Apple trees of bearing age in 1910 numbered 581,767; those not of bearing age, 269,044. The production in 1909 was 362,800 bushels, valued at $276,410. The production of the other orchard-fruits was as follows: 65,680 bushels of pears, valued at $67,685; 48,754 bushels of plums and prunes, valued at $37,555; 10,987 bushels of cherries, valued at $15,880; 504 bushels of apricots, valued at $620; 534 bushels of quinces, valued at $587; and 369 bushels of mulberries, valued at $336.

The production of grapes in 1909 was 2,016,506 pounds, valued at $88,620. Grape-vines of bearing age in 1910 numbered 79,708; those not of bearing age, 19,704.

Nuts were produced in 1909 to the amount of 376,013 pounds, valued at $26,888. The production of the various nuts was 159,823 pounds of pecans, valued at $20,442; 185,252 pounds of black walnuts, valued at $3,672; and 28,160 pounds of Persian or English walnuts, valued at $2,583. Of the tropical fruits, 975,136 pounds of figs were produced, valued at $49,169.

Of the small-fruits, the strawberries are the most important of those grown in South Carolina. Strawberries increased in acreage from 499 in 1899 to 815 in 1909, when the production was 1,337,208 quarts, valued at $108,938. Blackberries and dewberries decreased in acreage from 39 in 1899 to 38 in 1909, when the production was 64,754 quarts, valued at $3,710. Other small-fruits produced were 4,955 quarts of raspberries and loganberries, valued at $477; 999 quarts of currants valued at $102; and 183 quarts of gooseberries, valued at $27.

Concerning the potatoes and other vegetables in

South Carolina, the sweet potato increased in acreage from 48,831 in 1899 to 48,878 in 1909, when the production was 4,319,926 bushels, valued at $2,606,606. Potatoes increased from 8,068 in 1899 to 8,610 in 1909, when the production was 782,430 bushels, valued at $609,424. Of the other vegetables the more important were: 1,828 acres of cabbage, valued at $270,675; 5,051 acres of watermelon, valued at $146,418; 1,773 acres of asparagus, valued at $138,317; 962 acres of cucumbers, valued at $115,247; 1,732 acres of beans, valued at $109,865; 977 acres of cantaloupes and muskmelons, valued at $58,490; 49 acres of lettuce, valued at $26,499; and 146 acres of tomatoes, valued at $12,633. Vegetables of lesser importance were beets, carrots, sweet corn, onions, green peppers, radishes, and squash.

The acreage devoted to the production of flowers and plants in South Carolina decreased from 28 in 1899 to 23 in 1909. The total area under glass in 1909 was 74,318 square feet, of which 66,242 were covered by greenhouses and 8,076 by sashes and frames. The value of the flowers and plants produced in 1909 was $52,094, as compared with $7,920 in 1899.

The acreage devoted to nursery products decreased from 84 in 1899 to 21 in 1909, when the value of the nursery products was $4,409, as compared with $4,416, their value in 1899.

C. C. Newman.

Georgia.

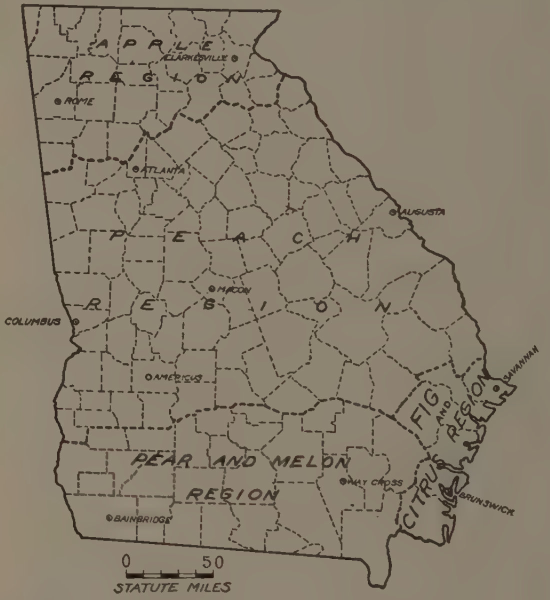
Georgia (Fig. 2514), one of the original thirteen colonies, is located in the southeastern part of the United States just north of Florida. It is the largest state east of the Mississippi. It extends from 30° 31′ 39″ N. on the south to 35° on the north, and its greatest breadth is found between 81° W. on the east and 85° 53′ 38″ on the west. From Savannah to Brunswick the boundary is the Atlantic Ocean, and from the coastal islands to some 30 or 40 miles inland the territory is practically at sea-level, the soil being alluvial and sandy; the climate here is subtropical, and such plants as the palmettos, figs, olives, and citrus flourish.

From the coast section along the Florida border, west to the Alabama line and as far north as Columbus, Macon and Augusta, through which cities the fall line passes, is found the great Atlantic Coastal plain. This section of the state is known as South Georgia; it has an elevation from the sea-level to 500 feet, the average being around 250 feet. The soil is mostly sandy, underlaid with clay, with an occasional outcropping of the underlying clay. This is a great cotton, melon and peach section. North of the fall line to Cartersville and Gainesville is found the Piedmont plateau. The country is very hilly and broken, the elevation being from 500 to 1,000 feet. The soil is mostly red clay, producing cotton, peaches and grapes. From Cartersville east and to the northern border of the state is located the mountain section. This region is rugged and broken, starting with an elevation of 1,000 feet on its southern border and reaching 5,000 feet in the north-central part. Here the apple attains perfection, and peaches do extremely well. The native forests contain such trees as the hemlock, white pine, and tulip tree. From Cartersville north and west is found the Appalachian Valley region. This is comparatively small in extent, is hilly and rugged, the elevation being from 500 to 1,200 feet. In all other parts of the state the geological features are comparatively simple, but here they are mixed and intricate. The apple and peach succeed well in this section. The extreme northwestern corner of the state dips into the Cumberland plateau, which section, however, is so small as to be practically negligible in a study of Georgia.

From the rice- and palmetto-covered islands of the coast, through the vast cotton fields, peach orchards and long-leaf pine forests, to the rhododendrons and white pines that cover the mountains in the northern parts, one passes through eight of the nine climatic belts represented in the United States. The mean temperature of the mountains runs from 40° to 60°; that of the Piedmont plateau from 60° to 65°; and that of the Coastal plain from 60° to 70°. Zero temperatures have been reported from nearly all parts of the state, but from the southern parts such reports are exceedingly rare. The maximum summer temperatures will run from 95° to 102°, the latter, however, being the great exception. The rainfall reaches a maximum of 71.7 in the northeastern corner of the mountain section and a minimum of 39.4 inches in Swainsboro, a little southeast of the center of the state: the average is 49.3 inches. This variety of climates, coupled with a great diversity of soils, proves the horticultural possibilities of Georgia to be little less than marvelous.

The Horticultural Society has divided the state into four sections, following to some extent the geological divisions:

1. The Mountain region takes in all the mountain section, the Appalachian Valley, the Cumberland Plateau, and a small strip of the Piedmont Plateau. This region is particularly adapted to the apple and late peach; quinces, cherries, currants, gooseberries, and other fruits of like climatic requirements also do well here, though they are not as yet of commercial importance. Cauliflower, celery and many other vegetables can be raised in this section, and a trade is growing up in late tomatoes and beans. The leading horticultural interests of the mountains at the present time are apples and peaches.



2514. Georgia, with the fruit and melon districts.

2. The Middle region, the largest division of the state, takes in most of the Piedmont Plateau and the northern half of the Coastal Plain. It is in the south-central section of this division that the mammoth peach orchards of the state are located. The Japanese plum, as well as other types, used to be extensively grown in this section, but the trees proved to be so susceptible to "plum wilt" and various other diseases and insects that the industry has fallen to a low ebb. Grapes of the Labrusca and rotundifolia types do exceptionally well in central Georgia; apples do fairly well in the northern part of this division, and melons prosper in the southern part. Figs, pecans, and most vegetables,

especially the sweet potato, thrive throughout this whole section; there is, however, little trucking, except for local markets.

3. The Southern region takes in the lower half of the Coastal Plain, and extends across the whole state from the Okeefeenokee Swamp, west. This region is especially noted for its melons, pecans, and Kieffer pears. Some trucking for early market is done and the industry is growing. Figs grow exceptionally well in this section, and there are numerous citrous trees in the southern tier of counties that have produced fruits for some years past without protection.

4. The Coast region takes in the tier of counties along the coast, and extends from South Carolina to Florida; it is the smallest section of the state. Figs are here found at their best, and various citrous fruits grow well on the islands; at one time the indigo and olive were cultivated on these same islands, but now their culture has been abandoned. Trucking is followed in this region for the northern market, strawberries, onions, cabbage, potatoes, tomatoes, and peas being the main crops.

Georgia is the mother state of the Elberta peach, the Belle, Waddell, and several others of commercial importance. Fifty-five apples have originated within its borders, the most prominent of which are the Yates, Terry, Shockley and Nick-a-jack. The LeConte is its addition to the list of pears; it has added the Georgia Giant, the Atlanta, the Senator and others to the pecans, and its best-known melon is the Georgia Rattlesnake.

At the present time the greatest horticultural industry in the state is the peach business, and second to that come the melons. The apple industry is rapidly coming to the fore, and in several sections specialized trucking interests are growing up. Georgia is well infested with diseases and insects, and consequently, the growers find that constant spraying is essential to success. For several years orchards have been sadly neglected, mainly because they were larger than could be well taken care of, but that time is now past, and improved methods are rapidly taking their proper places.

There has been a slight decrease in the number of peach trees during the last decade; those removed, however, were old or neglected trees, which materially reduced the yield to a tree. The peach crop of 1908 was the largest in the history of the state, being about 7,000 carloads. In 1909 the crop was 904 carloads, and in 1910 the state shipped 6,289 carloads. The apple industry is rapidly increasing, thousands of trees being planted every year. The pecan interests are also enlarging; although the Census shows only 75,519 bearing trees, there are, young and old, 400,000 or more now growing in the state.

Small-fruits are not of so much importance, strawberries being the most widely grown.

The trucking interests are on the increase, proportionally as the pine forests of the southern part of the state are cleared up and settlers take charge of the warm sandy lands.

One of the promising new vegetable industries is the raising of asparagus, which is being carried on around Fort Valley and Marshallville. The raising of early truck in the southern parts of the state is now a well-established business, and a late truck industry is growing up in the mountain sections of the north. This latter interest is going hand in hand with the apple business.

The nursery interests of the state are fairly large, but only some three or four concerns have attained any great prominence.

Probably the two best-known horticultural products are the Georgia peach and the Georgia watermelon. The introduction of the refrigerator car made the conversion of cotton fields into peach orchards a possibility. Cheap lands and cheap labor combined with a favorable climate helped in the planting of the enormous orchards that the state is noted for. The industry has now undergone the extensive stage and is rapidly becoming intensive. The melon business seemed to be natural to the soil and climate; it has attained vast proportions and is becoming more remunerative through the use of better methods.

Pecan-growing is now one of the most important new industries of the state; there are several instances on record where bearing orchards have been sold for as much as $1,000 an acre. The apple orchards in the northern part of the state are vying with the pecans in public interest; lands in the mountains that could be purchased for $1 to $5 an acre twenty years ago are now being sold for $25 to $100 an acre for apple purposes. Numerous large orchards have been planted, but most of the plantings are small and are being brought into bearing along the most improved lines.

Horticultural collections and parks are scarce, those worthy of note being the Nurseries and Evergreen Collection of the Fruitland Nursery Company, near Augusta. The Ferrell Gardens, at LaGrange, are of particular interest, as they are the only remaining specimen of the old colonial landscape architecture. The Payne and Wade estates, near Thomasville, are magnificent examples of present-day landscape gardening, the former being noted for its collection of azaleas.

Georgia has been fortunate in having a great many individuals who have bent their efforts toward advancing horticulture long before this matter was taken up and given serious consideration by the authorities and the powers of the state. Some of these men are: Jarvis Van Buren, a native of Clarksville, who was especially interested in the dissemination of the apple in that section; James Camak, a native of Athens, who, with Van Buren, revised and published the second edition of "Gardening for the South," which was written by Wm. N. White, a sketch of whose life may be found in Volume III, p. 1602. P. J. Berckmans probably stands out as one of the greatest advancers of southern horticulture. He was a man of international reputation. A fuller discussion of his life may be found in Volume III, p. 1565. Jas. B. Hunnicutt, the author of "Agriculture for the Common Schools," and for a long time editor of the "Southern Cultivator," is also a man whose life work was mainly given for the advancement of Georgia's agriculture, but his paper always carried a horticultural section in which he was particularly interested.

Public-service agencies for horticulture.

The Land-Grant College of Georgia was opened in 1872 as a subdivision of the University of Georgia in Athens. In 1906 the Conner bill was passed by the Legislature of Georgia reorganizing this institution. The reorganization took place in 1907. At the time of the reorganization the department of horticulture in the old College of Agriculture had one instructor in charge with very meager equipment. At the present time the department consists of three faculty members. The department of horticulture is also represented in the graduate school of the University of Georgia.

The Georgia Experiment Station was originally located in Athens in 1888; in 1889 it was removed from under the Board of the University of Georgia and placed under a special Board appointed by the Governor and located at Experiment, two miles from the city of Griffin. At present the Station has one horticulturist, and there are twenty acres devoted to orchard and truck plats, there being approximately 325 varieties of fruits and the like represented. The strictly horticultural publications of the Station are thirty-two to the present date.

In the educational system of Georgia there are Congressional District Agricultural Schools. At the present time eleven districts have these institutions in operation. They are really secondary agricultural schools and horticulture is taught. The North Georgia Agricultural College, subdivision of the University of Georgia, located at Dahlonega, also offers instruction in horticulture. The general agriculture required in the grammar schools has some horticultural instruction, but this is mostly elementary and curtailed in its extent. There are no private schools offering courses along this line within the state and none offering work for a degree except the Georgia State College of Agriculture, of the University.

The extension work in horticulture is carried on directly through the department of horticulture of the Georgia State College of Agriculture. The special extension work along horticultural lines at the present time consists in the running of coöperative experiments in various sections of the state on the different horticultural crops; the organization of small truck and fruit coöperative associations; the assisting of the various demonstration agents, many of whom are located in sections directly interested in horticulture. The department is also making efforts to facilitate and help in the landscaping of the school buildings of the small towns and rural districts. The time of one man is devoted absolutely to the extension work and when necessary other members of the department assist in the extension movement.

There is no state board of horticulture in Georgia. In 1897 an act was passed by the Legislature establishing the State Board of Horticulture and Pomology, but in 1898 this act was amended, changing this Board into the State Board of Entomology. This Board instituted a State Department of Entomology and appointed a State Entomologist.

The regulations of the State Board of Entomology require that nurseries be inspected annually for the various diseases and pests that are on their prescribed list. It also requires that every plant of any kind that is shipped into or from the state of Georgia must have an inspection tag of the Board of Entomology attached thereto.

In 1876 P. J. Berckmans founded the Georgia State Horticultural Society, at Macon. This organization has persisted until the present time.

Statistics (*Thirteenth Census*).

The approximate land area of Georgia, according to the census of 1910, is 37,584,000 acres, of which 71.7 per cent, or 26,953,413 acres are in farms. Of this farm land, 45.6 per cent, or 12,298,017 acres are improved; 13,002,741 acres are in woodland; and 1,652,655 acres are classified as other unimproved land in farms. The number of all the farms in 1910 was 291,027. The average acreage to the farm was 92.6. [The total area is 59,265 square miles.]

The leading agricultural crops are cotton, cereals, forest products of farms, sugar crops and hay and forage. In 1909 the value of the cotton crop, including cotton seed, was $149,937,058, or 66.2 per cent of the total value of all the crops. The cotton crop in 1909 occupied 39.7 per cent of the improved land area, or 4,883,304 acres, as compared with 3,513,839 acres in 1899. The cereals occupied 3,906,703 acres in 1909 or 31.8 per cent of the improved land area, and the production of cereals was valued at $42,405,019, which was 18.7 per cent of the total value of all crops. The value of the forest products of the farms was $8,938,390 in 1909 as compared with $3,217,119, their value in 1899. The acreage of sugar crops in 1909 was 52,707; in 1899 it was 37,609 and the value of the sugar crops in 1909 was $2,689,056, as compared with $1,731,296, their value in 1899. Hay and forage increased in acreage from 137,312 in 1899 to 253,157 in 1909, an increase of 84.4 per cent. The value of the hay and forage produced in 1909 was $4,056,907, thus making hay and forage above the sugar crops in point of value.

Horticultural crops grown in Georgia are fruits and nuts, vegetables, including potatoes and sweet potatoes and yams, peanuts, small-fruits, and flowers and plants and nursery products. The value of the fruits and nuts in 1909 was $3,143,114, as compared with $673,189, their value in 1899, showing an increase of 366.9 per cent in value. In 1909 the total acreage of vegetables was 187,328 and their value $10,614,601. The production of peanuts was 2,569,787 bushels, from a reported acreage of 160,317, and their value was $2,440,926. Small-fruits decreased in acreage from 1,634 in 1899 to 988 in 1909, and the value of their products in 1909 was $111,754. The growing of flowers and plants and nursery products is of some importance in Georgia. The acreage increased from 1,034 in 1899 to 1,646 in 1909, an increase of 59.2 per cent. The value of the flower and plant and nursery products in 1909 was $637,860.

The production of orchard-fruits in 1909 was 256.8 per cent greater than in 1899, the total quantity produced in 1909 being 3,670,830 bushels, valued at $2,930,793. Peaches and nectarines contributed about two-thirds of this quantity and apples and pears most of the remainder. The production of peaches and nectarines in 1909 was 2,555,499 bushels, as compared with 259,728 bushels, the production in 1899, and their value in 1909 was $2,182,613. The production of apples in 1909 was 895,613 bushels, valued at $555,744; that of pears 149,667 bushels, valued at $134,604. The production and value of the other orchard-fruits in 1909 follow: plums and prunes, 60,845 bushels, valued at $46,366; cherries, 4,979 bushels, valued at $7,199; quinces, 2,021 bushels, valued at $2,272; mulberries, 1,766 bushels, valued at $1,449; and 440 bushels of apricots, valued at $546.

In 1910, the number of grape-vines of bearing age in Georgia was 277,658; those not of bearing age 38,233. The production of grapes in 1909 was 2,767,366 pounds, valued at $99,216; the production in 1899 was 8,330,485 pounds.

The value of all nuts produced in 1909 was $61,106. The production was 845,553 pounds. The leading nuts grown, their production and value for 1909 follow: pecans, 354,046 pounds, valued at $47,845; black walnuts, 427,607 pounds, valued at $8,598; and 56,585 pounds of Persian or English walnuts, valued at $4,161. Other nuts growing in Georgia are hickory-nuts, hazel-nuts, Brazil-nuts, Japan-nuts, chestnuts, beech-nuts, almonds and others.

The tropical fruits produced in Georgia in 1909 were valued at $51,999. The most important of these, their production, and value were figs, producing 1,183,494 pounds, valued at $50,326, and pomegranates, producing 27,365 pounds, valued at $920.

Strawberries are by far the most important of the small-fruits raised in Georgia. In 1909 the production, from 890 acres reported, was 1,157,472 quarts, valued at $101,161. The production of blackberries and dewberries was 67,285 quarts, valued at $5,594; that of raspberries and loganberries, 33,928 quarts valued at $4,663. Other small-fruits of minor importance are currants and gooseberries.

Of the vegetables in 1909 the sweet potatoes and yams were by far the most important. The production of sweet potatoes and yams from a reported acreage of 84,038 was 7,426,131 bushels, valued at $4,349,806. The production of potatoes from a reported acreage of 11,877 was 886,430 bushels, valued at $684,427. The area of other important vegetables grown in 1909 and the value of their products follow: watermelons, 16,298 acres, valued at $410,147; cantaloupes and muskmelons, 3,022 acres valued at $209,161; green beans, 1,484 acres, valued at $102,488; tomatoes, 756 acres, valued at $57,270; cabbage, 806 acres, valued at $57,191; and turnips, 445 acres, valued at $29,470. Vegetables of less importance grown were asparagus, beets, sweet corn, cucumbers, lettuce, onions, green peas, green peppers, and squash.

The acreage occupied by the flower and plant industry in Georgia in 1909 was 144 acres and the value of the products $271,427. The area of land under glass was 867,222 square feet, of which 741,672 square feet were covered by greenhouses and 125,550 square feet by sashes and frames.

The area on which nursery products were grown in 1909 was 1,502 acres, an increase of 56.9 per cent since 1899, when the area was 957 acres. The value of the nursery products in 1909 was $366,433, as compared with $172,143, the value of the nursery products in 1899.

T. H. McHatton.

Florida.

The history of horticulture in Florida (Fig. 2515) dates from the earliest settlements, and even prior to that period the aborigines carried on a desultory plant-growing. The peculiarity of the soil, however, prohibited the extension of this work except in a few isolated places. It was necessary to introduce commercial fertilizers before horticulture could make rapid progress in this state. Up to the time of commercial fertilizers, it was thought that the hammocks were the only places capable of raising fruit, the remainder of the arable land being so sandy and wanting in plant-food that remunerative crops could not be grown on it excepting after it had been "cow-penned."

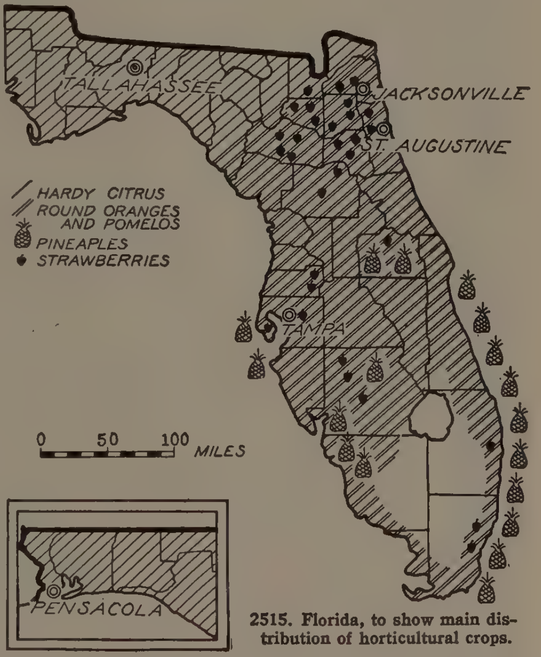
Such a soil, containing often over 90 per cent sand and insoluble matter, at first sight would seem to be absolutely worthless for horticultural purposes, but with the advent of the new horticulture it becomes the ideal soil. It is a lodgment for plants in which occurs no material that will prove deleterious to the crop, and all that is necessary is to add to it the material that will cause the plant to grow to the necessary size and produce fruit of the desired quality. Beautiful thin-skinned oranges grow only on land properly fertilized and not on soil impregnated with great quantities of organic nitrogen, i.e., fertile lands.

In building up the land from the ocean bed, referring especially to peninsular Florida, the wind and waves have sorted the particles to some extent and have elevated various parts more than others. The separation of the larger particles of sand from the finer, with a porous substratum, has produced what is called a "scrub." The railroad surveys indicate that the maximum elevation in peninsular Florida is about 300 feet. Thus it happens that, although this land is thirsty, it is rarely or never spent of its capillary moisture. The areas of scrubs may vary in size from a few acres or even less to many thousands, but they are always sharply defined, having a specialized flora. The soil in a hammock is of a finer texture and is not infrequently underlaid by clay. It often occurs that land of this texture is only a few feet above sea-level, or it may be elevated and rolling, but is always covered with a good growth of hardwood or of cabbage palmetto, or both. This class of land has long been desirable for horticultural purposes, and is still regarded as valuable. These regions are more or less isolated, and vary in extent. Such land usually contains sufficient fertility to raise several crops of vegetables. Flat woods land is usually level, varying in fertility from 96 per cent of sand and insoluble matter to that which will produce a crop of tomatoes. This class of land comprises about seven-tenths of the land of the peninsula. With proper treatment it raises good crops and is capable of remarkable improvement. The characteristic plant of this land is the long-leaved pine.

The foregoing discussion relates to the state independent of latitude and climate. The state is also divided into four regions, according to climate and latitude: (1) western Florida, that part of the state lying west of the Aucilla River; (2) eastern Florida, that part of the state lying between the Aucilla River and a line drawn from the mouth of the St. John's River to Cedar Keys; (3) central Florida, that part of the state lying between eastern Florida and southern Florida; (4) southern Florida, including the counties of Brevard, St. Lucie, Palm Beach, Dade, Monroe, Lee, DeSoto and Manatee.

Citrous fruits develop best on hammock and rolling pine land, preferring the cabbage palmetto hammocks or a hammock containing a mixture of palmetto and hard wood. The lime alone does well on the shell and coquina lands of southern Florida. The rough lemon stock is preferred in southern Florida, especially on the higher sandy lands. For western Florida the Satsuma orange is the best variety. For eastern Florida varieties that mature their fruit before Christmas may be planted. In central Florida all the varieties of Citrus do well, especially toward the south and in protected localities.

Peaches grow in all sections, preferring hammock or rolling pine land or even level pine land if perfectly drained, but the varieties best adapted to different regions vary considerably.



2515. Florida, to show main distribution of horticultural crops.

Plums, as a whole, are adapted only to western and eastern Florida, preferring hammock and rolling pine land. Burbank does well in the western section. In the eastern section Terrill, Botan and Burbank do well.

Of the pears, Kieffer, LeConte, and Smith do well in western and eastern Florida on hammock or rolling pine land.

Grapes grow rapidly, but need careful attention to be kept in good bearing condition for a period of years. Hammock land is preferable for them. The native varieties grow to an immense size and produce great quantities of fruit with minimum attention. Of *Vitis rotundifolia*, the Scuppernong and Thomas grow luxuriantly in all sections. Flowers grows well in western and central Florida.

The kaki, Japanese persimmon, needs good hammock land or well-drained high, or more or less undulating, rolling pine land. It is better adapted to western, eastern and central than to southern Florida.

Under favorable conditions, Jennings and Red Astrachan apples may be fruited in western Florida; Santa Fé apricot in western and eastern Florida. Figs do fairly well for home use and for canning or candying in eastern and central Florida. They need a compact, fine-textured soil.

Mulberries will grow on hammock or good quality of rolling pine land in all sections of the state. The following varieties have given good crops: Downing, Hicks and Stubbs. Pomegranates make a more or less ornamental fruit. Acid, Purple and Sweet do well in western, eastern and central Florida.

Pecans are adapted to various kinds of soils, especially from central Florida northward and westward. The best agricultural lands such as are considered the most suitable for the growing of cotton are best adapted to pecan-growing. The best stock on which to grow pecans is the pecan seedling. Much time and money has been lost in attempting to bud native species of hickory already established in the hammocks to pecans. While it is possible to secure good bearing trees in this way, it is usually financially unsuccessful. Leading varieties are the Curtis, Frotscher, Russell, Stuart, and Van Deman.

The growing of strawberries is controlled largely by efficient and reasonable transportation. If the crop cannot be placed upon the market promptly it is worthless. Probably nine-tenths of the fields of the state are planted on moist flat woods land, or what is locally known as gall-berry flats. Such land is cleared and thoroughly drained by means of open ditches. On such land strawberries begin to ripen in January and continue until May or June if properly cultivated, though the season of profitable shipment rarely extends beyond the middle of April. Especially prepared refrigerator cars are now carried by some railroads on express trains. The plants are usually set out every year, in August, September and October, and bear a good crop the following spring. The most successful strawberry growers continue to cultivate a part of the old field to secure new plants to be used the following fall for planting out the new field.

Pineapples find their most congenial habitat on spruce pine land. Soil from pineapple fields contains a large percentage of sand and insoluble matter,— as high as 98 per cent. The land must be well drained, free from any standing water, even during the rainy season. The most extensive pineapple area is located on the sand hills near the coast. The character of the vegetation and physical condition of these hills or dunes is essentially that of the scrub land of the interior. The slat sheds or pineapple sheds, which are constructed to afford a half shade, serve a good purpose in summer as well as in winter. In summer the slats reduce the amount of sunshine that reaches the plants and consequently the intensity of heat, though probably not the total warmth. In winter they interfere with rapid radiation, which would occur as the result of a sudden freeze or of a frost. The slat shed is a simple structure, the essential part of it being the roof or covering, which is made of boards or slats fastened so as to leave an opening between the boards or slats equal to the space covered by them. These vary in size from a common plastering lath to boards 4 inches wide. The height of the covering above the ground varies from 6 feet to rarely more than 10. The most extensive fields are located in southern Florida. Smaller areas have been planted in central Florida; nearly all of these are protected by sheds, some of the sheds being so constructed that the roof may be closed completely. The islands or keys underlaid with coralline limestone form one of the most suitable habitats for this plant, while the low, fertile islands or keys are worthless for a pineapple plantation. Red Spanish is cultivated more extensively than all the other varieties combined. It is a hardy variety, and one suited to extensive planting with a minimum amount of attention. For extensive culture, Egyptian Queen, Porto (Puerto) Rico and Ripley Queen do well generally. Smooth Cayenne is promising, because not spiny.

Bananas are cultivated only for local markets, but form a source of considerable revenue to a number of plantations. The land best adapted to them is a low, moist hammock or a bay head, especially such soil as is composed largely of muck. Baraçoa (Red Jamaica), Cavendish, Golden, Hart's Choice and Orinoco ("horse banana") are leading varieties in southern Florida.

The guava has attained considerable importance, though as yet it is not cultivated extensively. Plantations exist in various parts of the state, but the greater quantity used in canning and for jelly is collected from trees grown without cultural attention. Nearly all of the fruit is from seedlings that have originated from scattered seeds. Well-drained fertile soils are favorable locations, but the guava adapts itself to almost all classes of cultivated soil. The sweet varieties are preferred for dessert, while the sour kinds produce the largest amount of jelly. The total amount of jelly and other guava products produced in the state will amount to many carloads annually. The Cattley and Strawberry guavas, while more cold-resistant and delicious as fresh fruit, are less popular than the varieties derived from the American species.

Mangoes are being grown extensively for the northern markets. They are now being fruited in the southern part of central Florida. The large extension in production of this fruit, however, will take place throughout southern Florida, mainly toward the southward. Orchards of considerable size are being planted to budded varieties from India together with budded varieties that have originated in Florida. Some of these varieties that have originated in Florida from the seed of Indian varieties, appear to have better fruiting qualities than their parents. Good citrous soil is preferred for growing mangoes. The same cultural care that proves best for citrous fruits is also applicable to the mango. The fertilizer requirements of the mango are very similar to those of Citrus. Among the old seedling varieties, No. 11 is a favorite on the east coast, while seedlings belonging to the Bombay group appear to be more frequently planted on the west coast. Among the budded Indian varieties, Mulgoba has been most extensively planted. It has, however, proved disappointing in its productiveness, though the fruit has no superior. Sandersha has become well established. Cecil, belonging to the Cambodiana group is very productive and a favorite. A large number of varieties in the form of inarched trees, have been imported. These are now fruiting and in the course of the next decade or two there will be considerable opportunity for selection from the best of these.

Coconuts are confined to southern Florida and along the seacoast. While the trees continue to grow when transplanted to the higher lands, they need the low, moist lands of the coast for fruiting and for highest development.

The avocado is a salad fruit of American origin, having been cultivated by the Incas, by whom it was called "ahuacatl." Up to twenty years ago, little effort had been made toward propagating improved varieties of this fruit. With the settlement of extreme southern Florida came a rapid development in its propagation by budding. This is carried on almost as easily as in the case of citrus. A careful survey of the trees fruiting in south Florida in 1903 showed that about 3 per cent of the seedling trees bore commercially profitable crops. Budded varieties of the avocado may now be secured from the leading nurserymen in southern Florida. The range of bearing trees is northward to the southern part of central Florida. The leading varieties

LXXIII. North American horticulture.—An orange grove in Florida.

are Trapp for December and January fruit; Baldwin and Early for July fruit; Pollock for large mid-season fruit; and Family for a succession of fruits from the latter part of July until into October. The bulk of the seedling fruits mature from the latter part of July until the middle of October. The hard-shelled Guatemalan fruits introduced by the Department of Agriculture, ripen in February and March. The small Mexican avocados that produce bluish fruits are hardy to the northern limits of central Florida, but are not commercially valuable.

Almost the entire list of vegetables given in the seed catalogues may be grown in all parts of the state. The industry has now developed until it is competing closely for first place with citrous fruits. Originally the hammocks were preferred for the main production of truck crops. In more recent years and with the advent of extensive drainage systems, the level lands composing the flat-woods and drained areas have been planted to vegetables extensively. Watermelons, cantaloupes and cucumbers are grown mainly on the hammock or high pine land. Cabbage, cauliflower, beets and similar vegetables are most largely grown on the heavier, more compact soils. Celery is grown most extensively on level tracts, much of which were formerly under water. These tracts permit sub-irrigation, which may be cheaply carried out in the areas of artesian flow. Vegetables are now produced to greater or less extent on almost every character of soil in the state, including even some spruce-pine land, some of which by means of commercial fertilizers has been made productive of truck crops.

Truck-growing can be developed extensively only where an abundance of skilled or fairly skilled labor can be commanded at critical periods. As truck-growgrowing does not employ the grower's attention for more than six months in the year, this labor must be able to find additional employment in some other way. Various centers have specialized on trucking; the Hastings center in north Florida makes a specialty of Irish potatoes; Sanford specializes on celery; the Manatee River region produces truck in general; the Biscayne Bay region produces truck for the midwinter and early spring markets.

Among the prominent horticulturists of Florida, not now living, were: Dudley W. Adams, organizer of the Florida State Horticultural Society; E. H. Hart, introducer of many ornamental and useful plants; H. G. Hubbard, who gave special attention to citrous insects; F. W. Inman, organizer of the Florida Citrus Exchange; C. T. McCarty, who at the time of his death owned the largest pineapple plantation in the world; A. H. Manville, practical horticulturist; T. W. Moore, author of "Orange Culture for Florida;" E. O. Painter, who did valuable work in connection with the Horticultural Society; Rev. Lyman Phelps, by some called "the father of chemical fertilizing for citrous fruits in Florida"; Stephen Powers, editor of "The Florida Fruit Grower;" Pliny Reasoner (see Volume III, page 1593); and Denis Redmond, writer on horticultural subjects.

Public-service agencies for horticulture.

The Land-Grant college of Florida was established in 1883, when a site for it was selected at Lake City. In 1903 the name "Agricultural and Mechanical College" was changed by the Legislature to the "University of Florida," and in 1905 the Agricultural College was relocated at Gainesville. There is one professor of horticulture.

The Experiment Station was established in 1887 in connection with the Agricultural College at Lake City. It was removed to Gainesville on January 1, 1907. In 1906, a separate staff was appointed who were relieved from all teaching duties, thus giving their entire time to investigational work. Eleven of this staff are devoting their time to problems connected with horticulture. About seventy-five horticultural bulletins have been issued.

An Agricultural and Mechanical College for negroes is also maintained, in which horticulture is taught.

Extension work in horticulture is carried on in connection with the college and the county agents. In twenty counties, girls' canning clubs have been organized in connection with the public schools.

In 1911, the office of State Inspector of Nursery Stock was established. This office is filled by the professor of entomology.

Statistics (Thirteenth Census).

The approximate land area of Florida is 35,111,040 acres, of which 5,253,538 are in farms, or 15 per cent of the land area. Of the farm land, 1,805,408 acres, or 34.4 per cent, are improved; 3,007,638 are in woodland; and 440,492 acres are classified as other unimproved land in farms. The number of all the farms in the state in 1910 was 50,016. The average size of a farm was 105 acres. [The total area is 58,666 square miles.]

The leading agricultural crops grown are cereals, hay and forage, cotton (including cotton seed), and tobacco. The cereals in 1909 occupied 650,486 acres, which was 36 per cent of the improved land occupied, and the value of cereal products was $6,175,973, or 17.1 per cent of the total value of all crops. Hay and forage in 1909 occupied 54,729 acres, an increase in acreage of 148.8 per cent as compared with 1899, when the land occupied by hay and forage was 21,994 acres. Value of the hay and forage products, in 1909, was $847,485. Cotton (including cotton seed) occupied 263,454 acres in 1909, which was 14.6 per cent of the improved land area. The value of the cotton products in 1909 was $5,481,407, which was 15.2 per cent of the total value of all crops. The acreage of tobacco in 1909 was 3,987 acres, an increase of 93.9 per cent as compared with 1899, when it was 2,056 acres. The value of tobacco in 1909 was $1,025,476. The value of forest products from the farms in 1909 was $2,375,882, as compared with the value in 1899, when it was $648,412.

Horticultural crops grown in Florida are fruits and nuts, vegetables, peanuts, flowers and plants and nursery products, and small-fruits. The value of fruits and nuts grown in 1909 was $7,410,166, as compared with $1,203,373 in 1899. The acreage devoted to vegetables, excluding potatoes, sweet potatoes and yams, in 1909 was 57,600 as compared with 1899, when it was 26,762. The value of the vegetable products in 1909 was $6,314,313 as compared with $1,954,802, in 1899. The acreage of peanuts in 1909 was 126,150, from which were harvested 2,315,089 bushels, valued at $2,146,862. In 1909, 2,280 acres were occupied by plants and flowers and nursery establishments, an increase of 222 per cent as compared with 1899, when the number of acres thus occupied was 708. The value of these products in 1909 was $547,280, as compared with 1899, when their value was $163,557. The acreage of small-fruits in 1909 numbered 1,356 acres which produced products valued at $302,383.

The total quantity of orchard fruits produced in 1909 was 235,188 bushels, valued at $232,203. Peaches and nectarines and pears are the more important of the orchard-fruits. In 1909 the production of peaches and nectarines was 114,998 bushels, valued at $128,029; for the same time the production of pears was 98,223 bushels, valued at $80,119. Other orchard-fruits and their production and value for 1909 follow: plums and prunes, 17,169 bushels, valued at $18,976; apples, 3,405 bushels, valued at $3,849; mulberries, 924 bushels, valued at $671; cherries, 374 bushels, valued at $448; quinces, valued at $103, and apricots valued at $8.

The production of grapes in 1909 was 1,086,344 pounds, valued at $38,357. The value of the grapes produced in 1899, 1,684,700 pounds, was $56,420, showing a considerable decrease in value for the period.

The production of nuts in 1909 was 382,535 pounds, valued at $47,456. The pecan was by far the most important nut, the production in 1909 being 307,632 pounds, valued at $43,962. The production of Persian or English walnuts was, in 1909, 28,575 pounds, valued at $2,018; that of black walnuts 42,573 pounds, valued at $766; and 17,012 coconuts valued at $501.

The most important fruits produced in Florida are the tropical fruits, valued in 1909 at $7,092,150. More than half this value is contributed by oranges, and most of the remainder by pomelos (grapefruit) and pineapples. In 1909, 4,852,967 boxes of oranges were produced, valued at $4,304,987. The production in 1899 was 273,295 boxes. The production of pomelos, or grapefruit, in 1909 was 1,061,537 boxes, valued at $1,907,816; that of pineapples, 778,644 crates, valued at $734,069. Other tropical fruits of importance, their production, and value in 1909 were: tangerines, 34,871 boxes, valued at $64,082; lemons, 12,367 boxes, valued at $13,753; limes, 11,302 boxes, valued at $12,457; guava, 258,709 pounds, valued at $7,604; figs, 474,287 pounds, valued at $20,886; mangoes, 5,278 boxes, valued at $5,739; bananas, 10,048 bunches, valued at $5,638; avocados, 4,920 crates, valued at $10,100; and also kumquats to the value of $2,768; and Japanese persimmons, valued at $2,066.

Of the small-fruits raised in Florida, strawberries are the only one raised on a considerable scale. The total acreage, production, and value of small-fruits in Florida in 1909 was: 1,356 acres; 2,396,573 quarts; and $302,383. Of strawberries alone, there were 1,343 acres, which produced in 1909, 2,383,397 quarts, valued at $301,056. Blackberries and dewberries contributed $1,287 toward the total value of small-fruits; raspberries and loganberries $25; and currants $15.

Of the vegetables grown in 1909, the most important in value were the tomato, sweet potatoes, yams, and potatoes. The product from 12,338 acres of tomatoes in 1909 was valued at $1,839,233. The production of sweet potatoes and yams in 1909 was 2,083,665 bushels, valued at $1,231,238; the production of potatoes was 856,967 bushels, valued at $839,691. Other leading vegetables were: 5,013 acres of green beans, valued at $483,927; 3,028 acres of cabbage, valued at $434,558; 3,408 acres of cantaloupes and muskmelons, valued at $230,009; 825 acres of celery, valued at $417,578; 2,086 acres of cucumbers, valued at $354,770; 1,450 acres of lettuce, valued at $343,456; 296 acres of green peppers valued at $94,246; and 17,711 acres of watermelons, valued at $394,567. Other vegetables of less importance grown in Florida are asparagus, beets, cauliflower, sweet corn, eggplant, okra, onions, green peas, squash and turnips.

The acreage devoted to the production of flowers and plants in 1909 was 49; in 1899 it was 45 acres. The value of the products from flowers and plants was $69,106 in 1909; the value from these products was $41,417 in 1899. The total area under glass in 1909 was 711,787 square feet. Of this, 568,190 were covered by greenhouses and 143,597 by sashes and frames.

The acreage used in the production of nursery products was 2,231 in 1909, as compared with 663 in 1899, showing an increase in acreage of 236.5 per cent. The value of the nursery products in 1909 was $478,174, as compared with $122,140 in 1899.

P. H. Rolfs.

EAST SOUTH CENTRAL STATES.

Kentucky.

The state of Kentucky (Fig. 2516), while its interests have not been largely directed, in the past, toward the field of horticulture, is nevertheless, in its various parts, admirably adapted to nearly all the fruits and vegetables of the temperate zone, a fact which during the past decade or more, has been increasingly recognized. Its agriculture has been primarily concerned with the practices of general farming and live-stock production rather than with the more intensive requirements of fruit- and truck-growing.

Before the Civil War, the people of wealth and culture, in common with those of other classes, lived chiefly in the country rather than in the towns, which were small and comparatively unimportant. There are evidences yet remaining, in numerous old and stately country homes, surrounded by magnificent trees and old-fashioned gardens, to bear witness to the high appreciation of the people of those early days for the amenities of rural life. Even today, though the movement toward the town is here, as elsewhere, apparent, Kentucky is practically a rural community. With the exception of Louisville, all of its cities are still of modest size, the interests of whose people are closely interwoven with those of the country districts round about.

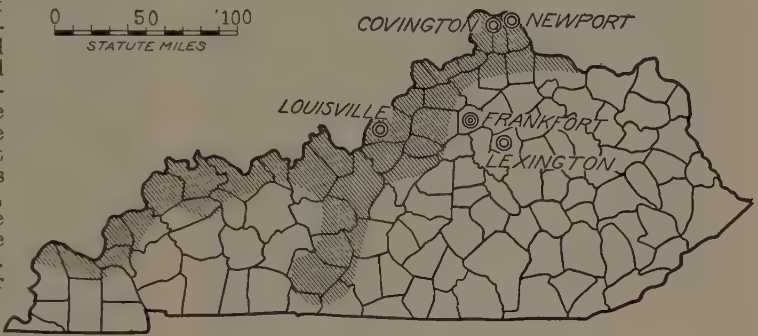
In the early years, therefore, there was little to stimulate the growth of commercial horticulture, but with the steady advance in fruit-growing throughout the country, and particularly as a result of better transportation facilities for perishable products, there have been developed, in recent years, several fruit- and vegetable-growing areas in which these industries have assumed extensive proportions. Broadly speaking, these areas may be said to include a more or less continuous band of territory of varying width, along the northern boundary of the state bordering the Ohio River down to its confluence with the Mississippi. A second region of horticultural importance includes a belt of counties lying to the south and southwest of Louisville, extending as far as Warren and adjacent counties in the southern part of the state.

Among the more notable of these centers of fruit-production is the Henderson apple district including Henderson and parts of the neighboring counties which have proved to be peculiarly adapted to the production of the Winesap apple. This variety has been more extensively planted in this section than any other kind, and being held in cold storage until the later winter months when other varieties of high quality have become scarce, finds a ready market at good prices, much of the product being shipped to southern cities. The interests of the community being centered largely upon this one fruit, there has naturally developed an organization for coöperation which has resulted in great economies in the purchase of spraying material and other supplies, though not as yet, in marketing the crop.

In this same region, also, along the bottom-lands more or less subject to annual overflow from the Ohio River, there is the promise of a new industry for this latitude in the growing of select varieties of the pecan. Upon both the Indiana and Kentucky shores of the Ohio, in this locality, are numerous groves of native pecan trees of great size, vigor, and productiveness. Here and there individual trees of great merit have been discovered which produce nuts of high value, from the standpoint of flavor, thinness of shell, size, and continuous productiveness. Some of these have been propagated by specialists who have discovered new and simpler methods for their multiplication, and are now being offered by nurserymen along with choice varieties of apples and peaches. Thoughtful students of this subject predict that here in Kentucky, as well as in the South, there is to be a large and important development of this horticultural industry.

Another fruit industry has sprung up during the past eight years in the strawberry-growing district in and around Warren County, with Bowling Green as its center. Here there is maintained a strong coöperative organization which has been so efficiently managed for the benefit of the growers that the strawberry area has increased from 55 acres the first year, to over 1,000 in 1914, with a large increase in prospect. After trials with various standard sorts, the Aroma has proved to be the most valuable kind for the soil and market conditions of this district, and is now grown almost exclusively, being shipped in carlots to many northern and eastern cities at prices which, upon the average, have proved very satisfactory to the producer. The yield is about 150 crates (24 quarts) an acre, although occasional yields of 200 crates are found, while a yield as high has 250 crates has been produced in a very few instances.

The county of Jefferson, containing the largest city of the state, Louisville, is the center of a district which is horticulturally important for both its fruit- and truck-growing interests. Owing to the proximity of the city, market-gardening has naturally extended to large proportions. Peaches and other orchard-fruits are profitably grown, but the district has become particularly noteworthy for two specialized industries, the growing of onion sets and second-crop potatoes. While a considerable area of early potatoes is produced under ordinary methods, the growing of the second crop is a unique industry which had its beginning in 1882, and has developed gradually until, in 1914, there were about 11,000 acres planted in the crop, giving a total yield of about 700,000 barrels. The second crop is planted between July 15 and August 1, and harvested in October. There are two coöperative organizations in the county which market most of the crop. A portion of the crop is held each year in cold storage for seed purposes. The varieties chiefly grown are the Carman No. 3, and to a less extent, the Irish Cobbler as seed stock for the usual first crop.



2516. Kentucky, with the horticultural parts.

In the hill country to the south and southwest of Louisville, apple- and peach-growing has for years been an important business, while to the northeast the peach orchards of Trimble County have for twenty years and over been a prominent feature. Throughout much of the fruit area mentioned, as in other parts of the state, the most favorable results are secured when advantage is taken of elevated locations, and of the cold-air-drainage resulting from the numerous deeply eroded river-channels.

In the vicinity of Cincinnati, Ohio, the fruit- and vegetable-growing interests are of considerable importance, although the conditions for market-gardening have resulted in a greater development of that business upon the northern than upon the Kentucky side of the Ohio River.

About two-fifths of Kentucky, comprising the entire eastern end of the state, is a mountainous country, rich in coal and other minerals, in which agriculture is confined, for the most part, to a few staple farm crops, which are produced, in many cases, by primitive methods, and with scanty returns. With the penetration of many new railroads into the heart of this vast area, and the opening of extensive mining enterprises, there is coming a fresh realization of its great fruit-growing possibilities. Here and there enterprising individuals have established orchards and gardens, thus showing the possibility of producing the fruits and garden products abundantly. For most of these products, there is an eager home market in the growing mining towns, and when the home demand is supplied, there are now numerous outlets to the larger markets of the cities.

The larger part of the public park areas of the state are located in Louisville, which now has a valuable series of such parks comprising a total of over 1,500 acres which, since their establishment about 1890, have been vigorously developed under the direction of the most skilful landscape architects. Until recent years, the small cities of the state, on account of their moderate size, have not so keenly felt the need of such public recreation grounds, but with added growth, they are now, for the most part, realizing this need and taking steps to supply it. The cities of Lexington, Owensboro, Covington, Henderson, Paducah, and others have already acquired, and have in use, various tracts of land to serve as a nucleus for further developments in this direction.

Of other public grounds in which the work of the landscape horticulturist is manifest, the two cemeteries, Cave Hill, of Louisville, and that of Lexington are perhaps the most notable examples in the state. The former comprises an area of about 300 acres, and is situated upon a beautiful tract of land, elevated 100 feet above the Ohio River. It contains several beautiful lakes, and is especially rich in its collections of aquatics. The cemetery at Lexington contains over 160 acres, and was established in 1849. It was exceptionally fortunate in being under the same superintendent, the late Charles S. Bell, from the beginning through a period of fifty-six years, and in having the landscape method of treatment followed from the first. Among many interesting horticultural features, the most notable today are the magnificent old bur oaks, white elms, and other trees, many of which are from 3 to 5 feet in diameter.

There is not yet full appreciation among Kentuckians of the remarkable resources in trees, shrubs, and herbaceous plants growing within the borders of the state, a flora so rich and varied that a fully satisfying scheme of landscape planting might anywhere be developed with access only to the native species. The widely varying conditions of soil, altitude, and climatic conditions, ranging from the high uplift of the Alleghanies in the east to the low bottom lands lying along the Ohio and Mississippi rivers in the west, have resulted in a natural assemblage of many of the finest tree and shrub species growing in North America. A list of the woody plants of Kentucky recently issued by the botanical department of the State Experiment Station (Bulletin No. 169) records the presence in Kentucky of twelve species of the Coniferæ, ten of willows, six of ash, seven hickories, nineteen oaks, five elms, and four magnolias. In addition to these, there are numerous other species in great profusion, including such interesting and valuable kinds as the tulip poplar (tulip tree), sycamore, the butternut and black walnut, sweet gum, cypress, the rare and beautiful yellow-wood (cladrastis), holly, dogwood, and red-bud, together with the rhododendrons, laurels, and numerous other shrubs of smaller stature.

Among the wild fruits and nuts, the black walnut is probably the most widely distributed and attains a large size in Kentucky, having long been the source of a valuable timber-supply. The nuts, while occasionally quoted in the general markets and extensively gathered for local consumption, have been prevented from coming into wide popularity because of their heavy shell and rather strong flavor. A fresh interest in this nut tree has been awakened through recent occasional reports of successful attempts to grow certain varieties of the English or Persian walnut by grafting them upon the common species. The shellbark and other hickory-nuts are produced freely in all parts of the state. The chestnut is also widely distributed, but is more abundant in the less fertile parts of the state.

Among other wild fruits of interest from the horticultural standpoint may be mentioned the persimmon and papaw, both of which grow commonly over most parts of the state, and are offered for sale to a limited extent in the late autumn months. As trees of both these species are sometimes found possessing fruits with fewer seeds, improved flavor, or other favorable variations, there is reason for expecting that much improvement may ultimately be secured.

Nurseries are scattered over most parts of the state, there being about forty in all, varying from extensive business enterprises with many employees to the little plot of an acre or less that is usually conducted by an orchardist for the propagation of a few trees for his own use.

Except in the larger cities and towns, commercial greenhouses are few, although in the hands of a number of enterprising individuals the results of growing both vegetables and flowers under glass have been very successful, and shipments of such greenhouse products are often made to other states. With a superabundant supply of valuable coal, there must inevitably come a better appreciation of the abounding opportunities for the development of such undertakings.

Public-service agencies for horticulture.

In common with other states, Kentucky enjoys the advantages of a College of Agriculture and Experiment Station, both of which are established as departments of the State University at Lexington. Horticultural education is given due recognition in its agricultural courses, and through coöperation with its Extension Division, with the State Board of Agriculture, and with the newly organized agency of County Advisers, is being effectively carried to the people.

The two state normal schools, located at Richmond in the east and Bowling Green in the west, are both actively engaged in promoting horticultural education.

The State Horticultural Society has had a long and varied history of over sixty years, being established in 1850. Never a large organization, and without financial aid from the state or other external sources, it has exerted an influence, with its little band of enthusiastic supporters, far out of proportion to its membership.

All the nurseries of the state are subject to annual supervision by the inspector of the State Experiment Station as a safeguard against the dissemination of dangerous insects and fungous pests.

Statistics (Thirteenth Census).

The approximate land area of Kentucky in 1909 was 25,715,840 acres. The land in farms was 22,189,127 acres or 86.3 per cent of the land area. The improved acreage in farms numbered 14,354,471; the acreage in woodland 6,951,626; and other unimproved land 883,030. In 1910 there were 259,185 farms in the state, the average acreage being 85.6. [The total area is 40,598 square miles.]

The leading agricultural crops of Kentucky are cereals, tobacco and hay and forage. In 1909 the production of cereals, from an acreage of 4,323,702, was valued at $60,738,651, which was 43.7 per cent of the total value of crops. The tobacco produced from 469,795 acres for the same year was valued at $39,868,753; and the hay and forage produced from 966,377 acres was valued at $10,306,344. While the value of the cotton produced in 1909 was only $246,614, the acreage increased from 2,396 acres in 1899 to 7,811 in 1909, an increase of 226 per cent. In 1909 there were also produced sugar crops to the amount of $1,420,504. The value of the forest products of farms was $7,843,142 in 1909, as compared with $4,179,480, in 1899.

The horticultural crops grown are fruits and nuts, small-fruits in limited amounts, vegetables including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts in 1909 was $4,661,634, as compared with $2,064,360 in 1899. The acreage of small-fruits decreased from 6,126 in 1899 to 4,387 in 1909, when the production was 4,972,702 quarts, valued at $357,597. In 1909 the total acreage of potatoes and other vegetables was 182,639 and their value $11,850,994, a decided increase over acreage and value in 1899. The raising of flowers and plants and nursery products was important, 791 acres being devoted to them in 1909, and the output valued at $508,372.

The total quantity of orchard-fruits produced in 1909 was 9,447,858 bushels, valued at $4,506,950. Apples contributed more than three-fourths of this quantity and peaches and nectarines most of the remainder. The production of apples in 1909 was 7,368,499 bushels, valued at $3,066,766. The number of apple trees of bearing age in 1910 was 5,538,267; those not of bearing age numbered 2,106,297. The production of peaches and nectarines in 1909 was 1,623,379 bushels, valued at $1,062,138. The number of peach and nectarine trees of bearing age in 1910 was 2,245,402; those not of bearing age, 1,110,744. The more important of the other orchard fruits produced in 1909 were: 251,536 bushels of pears, valued at $187,951; 139,346 bushels of plums and prunes, valued at $102,446; 52,163 bushels of cherries, valued at $74,340; and 11,537 bushels of quinces, valued at $11,757.

The number of grape-vines of bearing age in 1910 was 605,002; those not of bearing age, 77,626. The production in 1909 was 3,680,182 pounds, valued at $137,326. The production of grapes in 1899 was 5,134,215 pounds.

Of the nuts grown in 1909, the black walnut is by far the most important. The production of black walnuts was 793,970 pounds, valued at $11,384; that of pecans, 28,577 pounds, valued at $2,887; that of Persian or English walnuts, 35,825 pounds, valued at $1,499; that of chestnuts 16,619 pounds, valued at $714; and that of hickory-nuts, 71,347 pounds, valued at $735.

Blackberries and dewberries are the most important of the small-fruits raised in Kentucky, with strawberries and raspberries ranking second and third, respectively. The acreage of blackberries and dewberries increased from 1,024 in 1899 to 2,141 in 1909, when the production was 2,165,547 quarts, valued at $137,250. The acreage of strawberries decreased from 4,128 in 1899 to 1,553 in 1909, when the production was 2,114,929 quarts, valued at $159,765. In 1909 the production of raspberries was 558,529 quarts, valued at $50,472; that of gooseberries 118,338 quarts, valued at $8,661; and that of currants 15,159 quarts, valued at $1,429.

Of the vegetables grown in Kentucky the potato is the most important. In 1909 the production from 55,750 acres was 5,120,141 bushels, valued at $2,724,043. The acreage devoted to the sweet potato and yam produced, in 1909, 1,326,245 bushels, valued at $839,454. The acreage of all the other vegetables in 1909 was 115,007, and their value $8,287,497, both acreage and value being an increase over 1899. The more important of the other vegetables grown in 1909 were: 1,959 acres of onions, valued at $200,317; 3,574 acres of tomatoes, valued at $128,017; 5,041 acres of green beans, valued at $94,663; 1,690 acres of watermelons, valued at $70,144; 738 acres of cabbage valued at $63,288; 1,103 acres of sweet corn, valued at $35,758; and 594 acres of cantaloupes and muskmelons, valued at

$35,172. Other vegetables grown were asparagus, beets, celery, cucumbers, kale, lettuce, rhubarb, spinach and turnips.

The acreage devoted to the production of flowers and plants increased from 132 in 1899 to 249 in 1909, an increase of 88.6 per cent. The area under glass in 1909 was 1,363,002 square feet, of which 1,276,823 were covered by greenhouses and 86,179 by sashes and frames. The value of flowers and plants produced in 1909 was $392,409, as compared with $262,288 in 1899.

The acreage devoted to nursery products, on the other hand, decreased from 837 in 1899 to 542 in 1909, when the value of the products was $115,963, as compared with $114,749 in 1899. C. W. Mathews.

Tennessee.

The horticultural products of Tennessee (Fig. 2517) are greatly diversified on account of the varied soil and climatic conditions. A knowledge of the natural divisions of the state is essential to a thorough understanding of its adaptability to the various branches of horticulture.

The Unaka region, on the eastern border, contains about 2,000 square miles. A few of the peaks are over 6,000 feet above sea-level, and the average elevation is 3,000 feet. The soil is gravelly and thin, but contains areas that are fairly productive. Apples are grown to a limited extent.

The valley of East Tennessee is the next division. It contains 9,200 square miles and an average elevation of 1,000 feet. The soils are generally well adapted to fruits. Records taken at Knoxville during a period of forty-four years show an average annual rainfall of 48.73 inches. Strawberries are extensively grown for northern markets in Hamilton, Rhea, Roane, Blount, and Knox counties; commercial peach orchards in Rhea, Roane, Washington, and Bradley counties; there are few large apple orchards, but farm orchards indicate success in commercial orcharding.

A thousand feet above the valley of East Tennessee lies the Cumberland Tableland, containing 5,100 square miles. This section, for the most part, is poor, the soils being sandy and thin. There are, however, areas of land which produce fruits and vegetables of the highest quality. An apple and peach orchard of over 400 acres in Morgan County is the largest in the state. Irish potatoes of superior quality are an important crop in Cumberland County, and, with proper fertilizing, can be grown with profit in all parts of the plateau. The climate is particularly healthful.

West of the Cumberland Tableland is the Highland Rim, surrounding the Central Basin. The Rimlands have an area of 9,300 square miles and an average elevation of nearly 1,000 feet. This territory possesses a great variety of soils, some of which are highly fertile and well suited to orcharding. Numerous streams cut the land into valleys, which are generally deep and narrow.

The Central Basin, in which Nashville is situated, contains 5,450 square miles, with numerous elevations of 200 to 300 feet above the general level. The soil is fertile and well adapted to small-fruits and vegetables. The average rainfall at Nashville is 49.53 inches. The largest commercial apple orchards of the state are located in this section, in Maury and Williamson counties.

The next natural division is the valley of the Tennessee River. It has an elevation of about 360 feet and an area of 1,200 square miles.

The Plateau, or Slope, of west Tennessee is the most important horticultural region commercially in the state. It contains 8,850 square miles and has an average elevation of 500 feet. The soils are generally light, fertile and easily cultivated, but demand careful treatment to prevent serious damage by washing. There are extensive commercial orchards of apple and peach in Haywood, Weakley, Gibson, and Madison counties, but the principal horticultural products are truck crops of strawberry, tomato, early and second-crop Irish potato, lettuce, cabbage, pepper, and sweet potato. Humboldt is the principal center of the trucking industry, which is rapidly developing.

The last natural division, the Mississippi bottoms, has an area of 950 square miles and an average elevation of 295 feet. It is little used for horticultural purposes.

The possibilities of Tennessee for the cultivation of fruits and nuts are evidenced by the profusion of these products in a wild state. Wild strawberries are found thoroughly distributed. Blackberries thrive everywhere. In favorable localities they attain a very large size, surpassing in this respect some of the cultivated varieties. Wild blackberries are marketed in large quantities in many sections, but only the earliest named varieties are desirable for shipment. Red and black raspberries grow in most parts of the state; and in some sections the best of the wild blackcaps, when transplanted to the garden, give better results than any of the cultivated varieties. In cultivation, the raspberry succeeds best when heavily mulched. Wild grapes abound throughout the state. Plums are also found in profusion; and the Wild Goose variety is said to have originated in Tennessee. Other wild fruits are: dewberries, cherries, crab-apples, juneberries, pawpaws, persimmons, and huckleberries.

Of the nuts, chestnuts are most plentiful, especially in the hilly and mountainous sections. The chinkapin flourishes in east Tennessee. Black walnuts are exceedingly numerous. Hickory-nuts are common throughout the state. Pecans are native along the streams, attaining great size in the Mississippi bottoms, but the thin-shelled named varieties have not been generally successful. Hazel-nuts, and butternuts, or white walnuts, are also plentiful.

2517. Tennessee, marking the horticultural areas.

Some of the native seedling fruits are highly valued, especially apples, peaches and strawberries. Many well-known varieties introduced from other states are not satisfactory. This is especially true of winter varieties of the apple, of which the introduced kinds are not so well adapted to the climate and soils as those of local origin. This fact is becoming well established among practical horticulturists. It is only a few years since orchardists were planting varieties of winter apples originated in the North. After repeated failures to get first-class fruit of good keeping qualities, they have begun to use native seedling varieties. Some of them will doubtless be largely cultivated in the future. A few native varieties of winter apples have gained considerable popularity among commerical orchardists. The fruits of these sorts have commanded remunerative prices in competition with apples shipped from the North. Owing to the great diversity of soils and exposures in this state, it is very important to select varieties that are adapted to the conditions where the trees are to be planted. The fact that a desirable apple has been originated in east Tennessee is no proof that it will succeed well in all parts of this political division. On the contrary, it is likely to give good results only in certain soils and on certain exposures that are requisite for its proper growth and fruitfulness.

All the classes of fruits commonly grown in the northern half of the United States are produced in Tennessee for home and commerical purposes. Strawberries are shipped more largely to distant markets than any other fruit. The area in peaches is increasing rapidly. Summer apples are shipped from several sections.

Of the vegetables, tomatoes and Irish potatoes are the most important commercially. The following counties have been active in producing and shipping fruits and vegetables: Gibson, Weakley, Madison, Haywood, Shelby, Maury, Williamson, Lincoln, Hamilton, Rhea, Roane, Morgan, Bradley, Washington, and Knox. Peanuts are grown largely in Perry, Humphreys, Benton, Decatur, Hickman, and Wayne.

Many locations in East Tennessee are peculiarly well adapted to the culture of grapes. This is shown by the large exhibits of fine grapes made at the fall horticultural meetings. The local markets are well supplied with home-grown grapes during their season.

Such fruits as Japanese persimmon and English walnut have not been generally successful, though occasional trees that are healthy and productive are known in the state. The Paragon chestnut is a promising variety grafted on native stock. These fruits, and thin-shelled pecans, while offering little to the practical orchardist, are of interest to the amateur. The currant and gooseberry succeed only in the high mountains of east Tennessee, and in favored localities on the Cumberland Plateau.

The nursery business is extensively developed in Tennessee, the apple, peach, pear, and cherry being largely propagated. There are 695 nursery firms listed in the office of the State Entomologist, and about one-third of them are wholesale growers. The largest nursery interests are in Franklin, DeKalb, Warren, Bradley, Knox, and Sullivan counties.

The climate of Tennessee, with moderate temperature and abundant rainfall, is favorable for the growth of ornamental plants, and landscape gardening may be extensively developed in all parts of the state, the principal drawback being the difficulty of maintaining a luxurious growth of lawn grasses. In west Tennessee, Bermuda is more largely used than any other grass. Kentucky blue-grass is most successful in the Central Basin and can be well grown throughout middle and east Tennessee by the free use of lime and fertilizers.

No state in the Union, with the possible exception of North Carolina, has a greater number of indigenous woody plants. Among native deciduous trees the following are adapted to street, lawn and park planting: large trees—white elm, winged elm, sweet gum, black gum, black locust, honey locust, silver maple, scarlet maple, sugar maple, white ash, blue ash, bald cypress, shagbark hickory, pecan, basswood (linn), beech, gray birch, chestnut, catalpa, hackberry, black wild cherry, black walnut, Kentucky coffee tree, cucumber tree, tulip (poplar), sycamore, and the following oaks: black, willow, pin, red, Spanish, scarlet, post, chestnut, white; small trees—juneberry, sourwood, silver bell, hornbeam, water beech, Hercules' club, buckthorn, red-bud, yellow-wood, fringe, wild plum, wild crab-apple, flowering dogwood, umbrella tree, witch hazel, hawthorn, black haw, red mulberry, sassafras, hop tree. The following native shrubs are of value for ornamental planting: bladder-nut, stewartia, callicarpa, calycanthus, yaupon (deciduous holly), flame-colored azalea, pinxter flower, mock-orange, meadow-sweet, nine-bark, red ozier dogwood, flowering raspberry, elderberry, sumach, Carolina rose, pink-flowering locust, spice bush, waahoo, strawberry tree, coral-berry. Kalmia, rhododendron and leucothoë occur abundantly in the mountain sections, but they cannot be well grown in the lowlands. Of native conifers the shortleaf pine, Jersey pine, pitch pine, red cedar and Carolina hemlock should be extensively planted, though seldom used in landscape work, with the exception of the red cedar. Holly is indigenous along the streams, and is largely used in ornamental planting. Difficulty is experienced with the more common coniferous forms, such as are listed by nurserymen, except in the mountains. In the lowlands, the spruces and firs, and the white, Scotch and Austrian pines are short-lived, though sometimes growing vigorously to an age of fifteen to thirty years. Junipers, thuyas, retinosporas and arbor-vitæs are extensively planted and give satisfaction when skilfully cared for. Among broad-leaved evergreens, holly, *Magnolia grandiflora*, several varieties of box, abelia, mahonia, *Elæagnus Simonii*, and a few other forms grow well in almost all parts of the state. *Azalea indica* and *A. amœna* have been planted in city gardens, but have not proved successful. All the common hardy flowering shrubs grow luxuriously throughout Tennessee. In almost all parts of the state all classes of roses can be grown in gardens except the more tender teas. In the southwest part of the state such tender varieties as the Marechal Niel grow well with a little protection.

Hardy herbaceous plants are largely grown in Tennessee gardens, and their popularity is rapidly increasing. Among plants of this class, the following are recommended for all parts of the state: narcissus, tulip, hyacinth, *Lilium tigrinum*, *L. candidum*, *L. speciosum*, *L. auratum*, *L. Martagon*, lily-of-the-valley, German iris, Spanish iris, Japanese iris, peony, phlox, foxglove, pinks, bleeding heart, delphinium, Japanese anemone, chrysanthemum, funkia, rose mallow and mallow hybrids, candytuft, bluebells, columbine, gaillardia, oriental poppy, hollyhock, platycodon, Shasta daisy, golden glow, baby's breath, small-flowered double sunflower, hybrid pyrethrum, yellow and orange hemerocallis.

Among climbing plants, the best for covering walls in Tennessee are English ivy, Boston ivy, and *Evonymus radicans;* for porches and pergolas, grapes, Virginia creeper, trumpet creeper, Chinese trumpet creeper, Chinese wistaria, Japanese wistaria.

Public-service agencies for horticulture.

The University of Tennessee was established at Knoxville, in 1794, and the College of Agriculture, as a department of the University, accepted the provisions of the first Morrill land-grant in 1868–9. The professorship in horticulture was established in January, 1900. Until 1915 the professor of horticulture also served as horticulturist of the Experiment Station. The Experiment Station is also at Knoxville in connection with the college. To date thirty-three bulletins on horticulture, insects and plant diseases, have been issued by the Experiment Station.

Courses in horticulture are offered in the four normal schools of the state and as a part of the agricultural teaching in the county high-schools. Gardening is taught in many of the city schools.

The Division of Extension of the College of Agriculture has a specialist in horticulture and makes demonstrations in fruit- and truck-growing.

Thr work of inspecting nurseries is conducted by the State Department of Agriculture. The headquarters of the inspector are at the University.

Statistics (Thirteenth Census).

The approximate land area of Tennessee in 1910 was 26,679,680 acres. The land in farms was 75.1 per cent of the land area, or 20,041,657 acres. Of this land in farms, the acreage of improved land was 10,890,484; that of woodland 8,007,733; and other unimproved land in farms, 1,143,440. The number of all the farms in 1909 was 246,012, and the average acreage a farm 81.5. [The total area is 42,022 square miles.]

The leading agricultural crops of the state are cereals, cotton (including cotton seed) and hay and forage. The acreage devoted to the production of cereals decreased from 5,055,328 in 1899 to 4,136,647 in 1909, when the production was valued at $55,302,278, which was 45.8 per cent of the total value of all crops. Cotton, including cotton seed, increased in acreage from 623,137 in 1899 to 787,516 in 1909, when the production was valued at $20,682,187. Hay and forage increased in acreage from 645,617 in 1899 to 1,052,816 when the production was valued at $12,617,538. Tobacco increased in acreage from 71,849 in 1899 to 90,468 in 1909, when the production was valued at $5,661,681. The value of the forest products of the farms in 1909, was $8,510,710, as compared with $5,086,624 in 1899.

Horticultural crops produced are fruits and nuts, small-fruits, potatoes and other vegetables, flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $3,562,668, as compared with $1,606,054 in 1899. Small-fruits decreased in acreage from 12,944 in 1899 to 12,539 in 1909 when the production was 13,895,493 quarts, valued at $923,613. The total acreage of potatoes and other vegetables in 1909 was 167,234, and their value $10,430,975. Excluding potatoes, the acreage of other vegetables increased from 74,408 in 1899 to 100,055 in 1909, when the value of the production was $7,015,686. Flowers and plants and nursery products increased in acreage from 2,978 in 1899 to 4,215 in 1909, when the production was valued at $1,042,282.

The total production of orchard-fruits in 1909 was 6,484,550 bushels, valued at $3,459,077. Apples contributed nearly three-fourths of this quantity, and peaches and nectarines most of the remainder. The production of apples in 1909 was 4,640,444 bushels, valued at $2,172,475. The apple trees of bearing age in 1910 numbered 4,838,922; those not of bearing age, 2,117,246. The production of peaches and nectarines in 1909 was 1,579,019 bushels, valued at $1,055,379. Peach and nectarine trees of bearing age in 1910 numbered 3,163,737; those not of bearing age, 1,190,727. The production of the other orchard-fruits in 1909 was: 139,093 bushels of plums and prunes, valued at $86,743; 83,557 bushels of pears, valued at $78,448; 36,303 bushels of cherries, valued at $60,294; 4,421 bushels of quinces, valued at $4,045; and 1,677 bushels of apricots, valued at $1,657.

The production of grapes in 1909 was 1,979,480 pounds, valued at $85,423. The grape-vines of bearing age in 1910 numbered 338,758; those not of bearing age, 76,040.

The total production of nuts in 1909 was 783,570 pounds, valued at $14,041. Black walnuts were the most important of the nuts, the production in 1909 being 708,627 pounds, valued at $9,194. The production of the other nuts in 1909 was: 25,581 pounds of pecans, valued at $2,566; 16,409 pounds of chestnuts, valued at $1,127; and 23,246 pounds of hickory-nuts, valued at $566.

The value of the tropical fruits produced in Tennessee in 1909 was $4,127. Figs, the most important of the tropical fruits, were produced to the amount of 68,535 pounds, valued at $4,070.

Of the small-fruits grown in Tennessee, strawberries are the most important, with blackberries and dewberries ranking next. The acreage of strawberries decreased from 11,548 in 1899 to 10,761 in 1909, when the production was 12,339,584 quarts, valued at $835,739. Blackberries and dewberries increased in acreage from 733 in 1899 to 1,514 in 1909, when the production was 1,316,100 quarts, valued at $65,476. Other small-fruits produced were: 222,331 quarts of raspberries, valued at $20,931; 13,740 quarts of gooseberries, valued at $1,205; and 3,726 quarts of currants, valued at $261.

The acreage devoted to the production of potatoes in Tennessee increased from 27,103 in 1899 to 40,963 in 1909, when the production was 2,922,713 bushels, valued at $1,790,233. Sweet potatoes and yams increased in acreage from 23,374 in 1899 to 26,216 in 1909, when the production was 2,504,490 bushels, valued at $1,625,056. Peanuts decreased in acreage from 19,534 in 1899 to 18,952 in 1909, when the production was 547,240 bushels, valued at $386,765. The production of the more important of the other vegetables in 1909 was: 5,803 acres of tomatoes, valued at $426,714; 2,398 acres of watermelons, valued at $105,001; 2,300 acres of green beans, valued at $68,536; 1,189 acres of cabbage, valued at $64,714; 1,456 acres of cantaloupes and muskmelons, valued at $41,691; 807 acres of turnips, valued at $29,853; 235 acres of onions, valued at $15,068; 139 acres of asparagus, valued at $13,003; and 365 acres of sweet corn, valued at $11,246. Vegetables of minor importance in 1909 were beets, popcorn, cucumbers, lettuce, green peppers, rhubarb, and squash.

The acreage devoted to the production of flowers and plants increased from 140 in 1899 to 239 in 1909. The area under glass in 1909 was 1,236,874 square feet, of which 1,079,374 were covered by greenhouses and 157,500 by sashes and frames. The value of the production in 1909 was $344,579, as compared with $175,979 in 1899.

The acreage devoted to the production of nursery products increased from 2,838 in 1899 to 3,976 in 1909, when the value of the nursery products was $697,703, as compared with $474,133 in 1899.

Charles A. Keffer.

Alabama.

Alabama (Fig. 2518) has many natural features which promise eventually to make it a very important horticultural state. The varied classes of soils, the range in elevations from coastal to semi-mountainous and the different climates between the extreme southern and the extreme northern parts of the state, provide conditions under which many of the fruits of the subtropics and of the temperate zones may be grown very successfully. The average rainfall for the state is 55 inches, most of this falling in the winter months. The average maximum temperature approximates 85° in the summer months and it is seldom that the temperature in the winter falls below 18° F.

Within recent years, hundreds of northern settlers have located in the state and many of these have taken up fruit- and vegetable-growing on an extensive scale; at present the influence of this movement is greater in the more southern counties. Large tracts of freshly cut-over lands are being rapidly developed by different land companies and are being planted principally in pecans and Satsuma oranges.

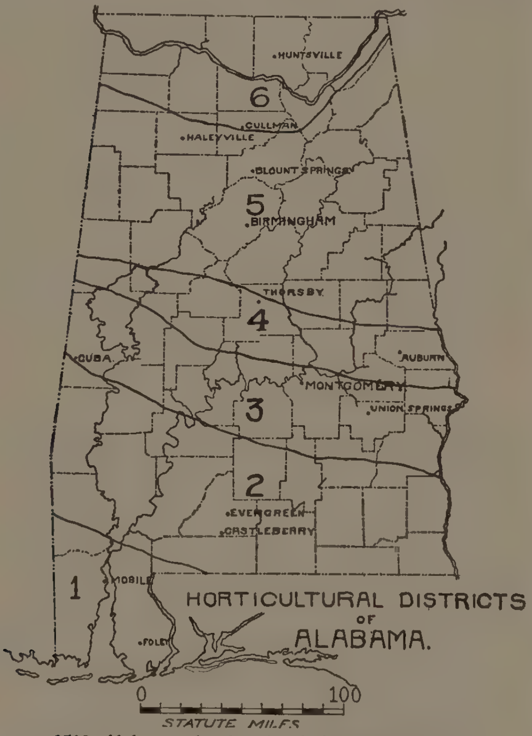
There are several large greenhouse establishments in the state, the largest of these being at Montgomery. The area of glass is being rapidly increased in Mobile and Birmingham and the smaller cities.

Beautiful out-of-door roses bloom in the spring and fall months and practically every home has its rose-garden. The climate being comparatively warm during ten months of the year furnishes rare opportunities for lovers of flowers.

The principal fruit- and vegetable-growing sections of the state are largely separated, and may be divided into six sections as shown on the map (Fig. 2518).

The light sandy loams of the Gulf section—Lower Coastal Plain (Fig. 2518, Area No. 1)—are particularly adapted to the growing of early spring vegetables for northern shipment. Mobile cabbage has become popular in the northern market and is, perhaps, grown more extensively in both Baldwin and Mobile counties than any other vegetable crop. In 1910, 714 cars of cabbage were shipped north from Mobile. As a rule, soils upon which cabbage is grown contain very little humus and as a result, considerable quantities of commercial fertilizer are used. The average cabbage-grower, under present conditions, realizes a very small net profit on his cabbage acreage. With scientific management the business should pay. There are many farms on which the percentage of clay is high and when cover-crops are grown on these soils some excellent crops have been produced.

Among other important vegetables grown in the Gulf region are snap beans, cucumbers, English peas, radishes and sweet potatoes, the latter being an important crop. Sweet potato yields average from 200 to 600 bushels an acre, and the average net return is 40 cents a bushel.



2518. Alabama, showing the six leading divisions.

The storage of large quantities of sweet potatoes under the old method is not always successful. The newer method of storage in connection with fire-curing is usually completely successful. At Summerdale in Baldwin County, a canning factory put up 1,000,000 cans in 1911. This industry is receiving considerable attention at present. The Nancy Hall, Dooley, and Early Triumph varieties are commonly grown.

Tomatoes have not been grown on a commercial scale successfully as a rule. "Wilt" and "blossom-end rot" are two diseases that are difficult to control and both are prevalent in the Gulf region. Also the Texas crop is on the market before the Alabama crop and prices are low when the latter comes on.

Watermelons are grown principally for the local market, although many cars are shipped North. They are planted about March 5 in the Gulf region and mature May 1.

Peaches have been successfully grown in the Gulf region, but there are only one or two commercial peach orchards now being operated. Elsewhere in the state are extensive commercial orchards; one at Atmore embraces 225,000 trees; another at Union Springs contains 1,000 acres. There are also large peach orchards at Blount Springs, Gadsden, and Alexander City. Brown-rot, San José scale, the plum curculio, and the peach tree-borer are the chief pests. San José scale has frequently done great damage before the grower became aware of the nature of the trouble. In this region peaches begin to ripen May 20 and the season extends to August 1 in the northern part of the state.

Japanese persimmons and some of the Japanese plums thrive in the Lower Coastal Plain. The work of the Department of Agriculture and of the Alabama Experiment Station in successfully ripening Japanese persimmons artificially, will give an impetus to the planting of this beautiful and splendid fruit. Persimmons properly ripened are little known outside of the Gulf states. Artificial ripening is chiefly of advantage in shipping the persimmons. They ripen naturally in October and November.

Figs, particularly the domestica group, are grown successfully over most of the state; they are seldom winter-killed and a few old trees will produce from six to ten bushels of fruit, and with the introduction of canning factories this fruit is being more widely exploited. It is difficult to ship the fresh fruit to the North but it has been accomplished successfully. There is a splendid market for the preserved product.

Grapefruit, guavas and so-called "native" sweet oranges are grown successfully in the extreme southern part of Baldwin and Mobile counties, but it is doubtful whether grapefruit will ever be grown on a large scale very successfully. A few ponderosa lemons are also planted about homes. Kumquats offer commercial possibilities and are being planted in a limited way. The fruit makes a delicious marmalade and preserve.

With the introduction of the Satsuma orange, many large nurseries have been established in the vicinity of Mobile, and this promises to be a center for this industry owing to the favorable soils and proximity to the extensive new plantings. Plantings now embrace about 1,500,000 trees, covering 10,000 acres, chiefly in Mobile and Baldwin counties.

The sand pear, although considered by many quite worthless, finds a ready market and is being grown successfully in this coastal section. It is resistant to blight and produces enormous yields.

A few of the early apples, such as Red June, Red Astrachan and Yellow Transparent, can be grown in a small way successfully even as far south as Mobile.

Both the bunch and muscadine grapes do well in the vicinity of Mobile, one instance being known at Flomaton where a grower netted $600 from one acre of bunch grapes.

In the past few years, there has been an immense increase in the planting of pecans, principally in the territory southward of Montgomery. The varieties in favor are Schley, Stewart, Frotscher, Delmas, Moneymaker, President, and others. There are now planted in the state, chiefly in the southern counties, between 250,000 and 300,000 pecan trees. These are grafted trees mostly.

The Upper Coastal Plain (Fig. 2518, Area No. 2) has not been an important section from a horticultural standpoint up to the present. The southwestern section is rapidly developing as a stock-raising region. Pecans are also being planted extensively there. At Evergreen and Castleberry there are large acreages of strawberries, and these towns are famous for the quality of berries they ship North each season. Berries are ready for market from April 1 to 10.

At Evergreen there is a rather novel horticultural industry. Carloads of southern smilax, commonly called "bamboo vine," are gathered in one-mule wagons by both whites and negroes, and are brought into warehouses and sold to shippers, much as cotton is sold. The smilax is carefully packed into light wooden boxes and shipped to northern cities. The season for shipping this evergreen comes just before Christmas, and holly is also gathered at the same time and shipped North.

In the Black Belt section (Fig. 2518, Area No. 3), a heavier type of soil is found. A few attempts at fruit-growing have been made but none of importance. There are splendid opportunities for small-fruit culture and vegetable-growing. Pecans thrive in this soil. In Sumter County there are many successful truck-growers, and this section ranks second to Mobile as a producer of early vegetables. There is a large fruit-farm in the vicinity of Union Springs in Bullock County where the possibilities of commercial fruit-growing have been demonstrated.

The Central Sandy Region (Fig. 2518, Area No. 4) is not adapted to commercial horticulture, although some excellent peaches are being grown in it. The Experiment Station is located at Auburn in the eastern part of the area. In parts of Lee, Chambers and Tallapoosa counties, fine bunch grapes can be grown.

The Mountain Region (Fig. 2518, Area No. 5) contains such diversified conditions of soil and elevation that it is difficult to describe specific features for the entire region. The counties of Blount, Cullman, Winston and Walker are especially adapted to fruit-growing and there are many large and successful orchards in these counties. On the elevated sites, the danger from frost is eliminated and the strong soils produce firm and beautifully colored fruit. The Elberta peach crop follows the Georgia crop and the market prices are generally good. Many fine apples are also grown, among which might be mentioned the varieties, Black Twig, Champion, Hackworth, Winesap, Shockly, Yates, Black Ben, Ben Davis, Delicious, Grimes Golden, and others. There are successful apple orchards at Ft. Payne and Gadsden. In the vicinity of Cullman, many fine apples are shipped North. The large settlement of Germans at this place has become famous for its successful farms, both general and horticultural. These farmers grow early varieties of sweet potatoes and the town is noted for its production of early strawberries. None of these farmers grows over 5 acres of strawberries, most of them less, but they are well organized and managed and receive maximum net returns. Excellent cantaloupes are shipped from Blount County every season.

The Tennessee Valley Region (Fig. 2518, Area No. 6) is perhaps the most beautiful and most fertile region of the state. At present it is "land poor," in other words, the plantations are too large for successful agricultural operations. The principal horticultural industry in this section is the large wholesale nursery business conducted in and about Huntsville. Owing to the original cheapness of the land and its peculiar adaptability to the growing of nursery stock, 2,500 acres are devoted to this work each year. The fruit-trees which are grown in the order of their importance are: peaches, pears, apples, cherries and plums. More land is now being devoted to ornamental stock than heretofore.

Among the men, no longer living, who have been especially influential in building up horticultural interests, may be mentioned W. F. Heikes. For many years prior to his death, he was in charge of the Huntsville Wholesale Nurseries, one of the largest nurseries in the South. From the time of the organization of the State Horticultural Society, until his death, Mr. Heikes was president of that organization. (See Volume III, page 1578.)

Public-service agencies for horticulture.

The Alabama Polytechnic Institute, which corresponds to the agricultural and mechanical colleges of other states, is located at Auburn. It was established in 1872. The duties of teaching and experimentation are, in most cases, performed by the same men.

The horticultural staff of the College and Station at present consists of the Professor of Horticulture and Horticulturist; an associate in horticulture, a field agent in horticulture, for experimental work only; and a graduate student assistant in horticulture. The equipment for College and Station consists, aside from the usual classrooms, offices and barns, of storage-rooms and a battery of two greenhouses connected with an extensive workroom, and canning equipment.

Elementary agriculture, which is a required subject in the public schools of Alabama, includes a small amount of work in horticulture. Horticulture is taught as a distinct subject in the ten agricultural schools of secondary grade, and in the state high-schools.

Extension work in horticulture is given in connection with other work at farmers' institutes, movable schools of agriculture and home economics, and in special meetings for the promotion of horticultural interests.

The Horticulturist of the Experiment Station is ex-officio Secretary of the State Board of Horticulture and State Horticulturist. This Board, under the horticultural law amended in September, 1915, is authorized to make quarantine regulations with reference to insects and diseases attacking fruit-trees and other plants.

The State Horticultural Society has been influential in fostering an interest in horticulture. It was founded in 1903. The Gulf Coast Horticultural Society, organized in 1914, a branch of the State Society, is devoted to the citrous interests and questions connected with the specialized horticulture along the Gulf coast of Alabama and similar sections of the neighboring states. A citrous exchange, modeled in a general way after the Florida Citrous Exchange, was organized in 1915 to market coöperatively the citrous and pecan crops. A similar oganization to handle truck crops was created shortly afterward. Both organizations have their headquarters in Mobile.

Statistics (Thirteenth Census).

The land area of Alabama, is 32,818,560 acres, of which 63.2 per cent or 20,732,312 acres are in farms. Of this farm area, 46.8 per cent or 9,693,581 acres are improved, 9,444,764 acres are woodland and 1,593,697 acres are classified as other unimproved land in farms. The number of all the farms in 1909 wers 262,901, and the average acreage to a farm 78.9. [The total area is 51,998 square miles.]

The leading agricultural crops are cotton, cereals, hay and forage, and forest products. Of these, cotton was the most important in 1909, producing about three-fifths of the total value of crops. The acreage of cotton in 1909 was 3,730,482 as compared with an acreage of 3,202,135 in 1899, showing an increase of 16.5 per cent. The value of cotton products in 1909 was $87,008,432. The land occupied by cereals in 1909 was 2,844,824 acres. In 1899 the area of cereals was 3,088,454 acres, showing a decrease of 7.9 per cent. The value of the cereal products in 1909 was $30,927,210. The acreage of hay and forage in 1909 was 238,656 with the products valued at $3,357,132. In 1899 there were 85,353 acres of hay and forage, showing an increase in the past decade of 179.6 per cent. The value of the forest products in 1909 was $6,308,151, as compared with $2,494,452 in 1899, showing an increase of 152.9 per cent in value.

The leading horticultural crops are vegetables, fruits and nuts, flowers and plants and nursery products. In 1909 the total acreage of potatoes and other vegetables was 150,567 and their value $9,842,784. The acreage of potatoes, sweet potatoes and yams in 1909 was 81,099. Their value in 1909 was $4,463,207. The acreage in 1899 was 60,370, showing an increase of 34.3 per cent. The acreage of other vegetables also showed an increase of 24.4 per cent during the same period. In

1909 there was an acreage of 69,468, with products valued at $5,379,577. The acreage in 1899, was 55,822. The value of the fruits and nuts in 1909 was $2,024,001; in 1899 the value was $573,763, showing an increase in value of 252.8 per cent. The acreage devoted to flowers, plants and nursery products was 3,199 in 1909 and 1,091 in 1899, an increase in acreage of 193.2 per cent. The value of flowers, plants and nursery products in 1909 was $427,296.

The total quantity of orchard-fruits produced in 1909 was 2,475,540 bushels, valued at $1,818,508. Peaches and nectarines contributed considerably more than one-half of this quantity, there being 1,416,584 bushels produced from 3,177,331 trees of bearing age. There were also 838,866 trees not of bearing age. The number of apple trees of bearing age in 1910 was 1,468,436; those not of bearing age, 737,689. The production in 1909 was 888,396 bushels of apples, valued at $620,745. The number of pear trees of bearing age in 1910 was 142,300; those not of bearing age, 99,170. The production of pears in 1909 was 100,041 bushels, valued at $86,866. The production of plums and prunes amounted to 61,712 bushels, valued at $45,039; that of cherries 3,588 bushels, valued at $4,873; that of quinces 2,740 bushels, valued at 2,944; that of mulberries 1,527 bushels, valued at $1,210, and of apricots 952 bushels valued at $950.

The production of grapes in 1909 amounted to 1,723,490 pounds, valued at $81,386. In 1910 there were 287,431 vines of bearing age and 77,105 vines not of bearing age.

The leading nuts produced are pecans, black walnuts, and Persian or English walnuts. The number of trees in 1910 were as follows: pecans, 44,683 of bearing age, 125,734 not of bearing age; black walnuts, 3,228 of bearing age, 1,753 not of bearing age; Persian or English walnuts, 3,022 of bearing age, 4,180 not of bearing age. The value of the nut products in 1909 were: pecans, $30,540; black walnuts, $3,447; English or Persian walnuts, $3,557. Almonds were also produced to the value of $51.

The tropical fruits grown are figs, oranges and pomegranates. In 1910 the number of fig trees of bearing age was 52,731; those not of bearing age, 33,893; orange trees of bearing age, 2,599; not of bearing age, 17,386; pomegranates of bearing age, 1,672; not of bearing age, 3,552. The value of figs in 1909 was $80,960; of oranges, $3,663; of pomegranates, $617. Pomelos (grapefruit) were also produced to the value of $359.

Of the small-fruits grown in Alabama, strawberries are by far the most important. The production, from 1,167 acres in 1909 was 1,848,537 quarts valued at $160,026. The acreage in 1899 was 607. The production of blackberries and dewberries in 1909 was 44,594 quarts valued at $3,726; 10,546 quarts of raspberries and loganberries with a value of $1,380; 2,452 quarts of gooseberries with a value of $177. The value of the currants and cranberries grown was $64 and $10, respectively.

The leading vegetables, their acreage, and value in 1909 were as follows: green beans, 842 acres, valued at $62,691; cabbage, 1,366 acres, valued at $208,754; tomatoes, 566 acres, valued at $47,322; watermelons, 4,708 acres, valued at $135,200. Other vegetables grown in Alabama were cantaloupes, muskmelons, sweet corn, cucumbers, onions, green peas, radishes, and turnips.

Alabama ranks fifth in the production of peanuts. The acreage increased from 78,878 in 1899 to 100,609 in 1909, an increase of 27.6 per cent. The production in 1909 was 1,573,796 bushels and their value $1,490,654.

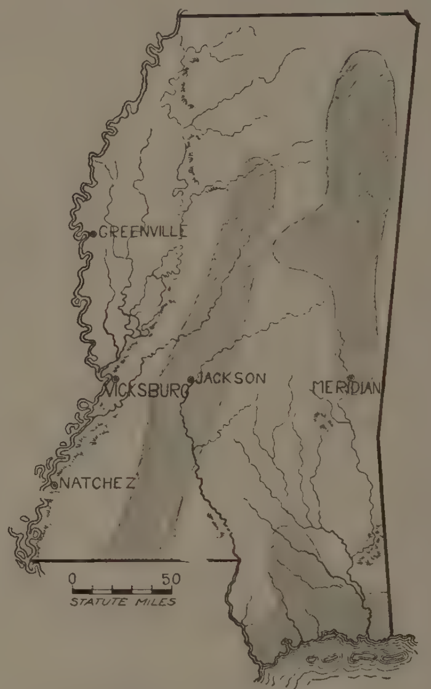
The area of land under glass in 1909 devoted to flowers and plants was 463,575 square feet, of which 435,400 were covered by greenhouses and 28,175 by sashes and frames. The value of flower and plant products in 1909 was $168,239.

The value of the nursery products in 1909 was $259,057.

P. F. Williams.
J. F. Duggar.

Mississippi.

Mississippi (Fig. 2519) extends about 325 miles from north to south and 175 miles from east to west. The surface is mostly undulating, with few abrupt hills, and the highest part of the state, the northeastern section, is less than 1,000 feet above the sea-level. It has an annual rainfall of about 45 inches in the northern part, the amount increasing to about 60 inches in the extreme south. The winter temperature is rarely as low as zero in any part of the state, while the extreme summer heat rarely reaches 100° in the northern part; near the Gulf coast 95° is the usual limit. The first frosts usually occur in November, and spring frosts are rare after the middle of March



2519. Mississippi, with the main areas.

The soil is extremely variable. The western part of the state, known as the Yazoo and Mississippi Delta, has one of the richest alluvial soils in the world, and one well suited for the growing of vegetables, besides cotton and corn, which grow to perfection here. The north-central part of the state consists largely of yellow clay hills, not very fertile and liable to serious injury from erosion, but with very fertile valleys between them, while the northeastern section has a strong lime soil which is very productive. Nearly all of the southern half of the state has a sandy loam soil underlaid with clay at a depth of a few inches, making those lands among the most desirable for the cultivation of either fruits or vegetables.

Although both fruits and vegetables are grown for export in all parts of the state, there are three districts in which horticultural work is specially prominent. These are the northeastern district, covering the territory along the Mobile and Ohio Railroad from Booneville south to Starkville and Meridian; the central district, covering the territory along the Illinois Central Railroad from Grenada south to Brookhaven; the Gulf-coast district, covering the territory along the Louisville and Nashville Railroad from Bay St. Louis east to Orange Grove; and along the Gulf and Ship Island road from Gulfport to Hattiesburg.

Peaches are grown more extensively than any other fruit, and are shipped to northern markets from nearly or quite every county in the state. The long growing season enables the trees to come into bearing rapidly, and a small crop of fruit is usually gathered the second year from planting, while the trees often continue fruitful from fifteen to twenty years. Although the trees themselves are never injured by cold, the fruit crop is occasionally cut short by spring frosts following warm winter weather, which sometimes brings the trees into bloom before the end of January. The early fruit is ready for market about the last of May, and shipments continue from that time until August, or later. Elberta, Mountain Rose, Georgia Belle, Lilly Miller and Chinese Cling are among the more popular varieties.

Pears grow well in all parts of the state, and, until about 1895, were planted more widely than any other fruit-trees, but since that time the blight has been so widespread and so severe that very few new orchards have been planted. Fully nine-tenths of the trees are either Le Conte or Kieffer, the latter being the more resistant to blight. In recent years the Sand pear, which does not blight in Mississippi, has been extensively planted and is the most prolific fruiter known.

Apple trees make a fair growth and bear well for some years, but become less vigorous with age, and are shorter-lived than in more northern latitudes. Nearly all varieties ripen during the summer and fall, and very few, even of the "long keepers," can be preserved through the winter. The fruit always commands a high price in the local markets, which makes the trees profitable, even though they last but a few years. Considerable fruit, mostly Early Harvest and Red June, is shipped from the northeastern district, but no other part of the state produces enough for a home supply.

Plum trees are of uncertain value. The Wild Goose and the Japanese varieties are the more common sorts, and while some trees and some orchards may grow well and bear heavily for many years, most of them succumb after producing two or three crops. Cherries are rarely successful. Figs are grown very commonly for home use in the central part of the state, and in the Gulf coast district are an important market crop. The fig does not succeed under orchard conditions, but a few trees grown near the house do well, and many of the older trees produce 1,000 pounds or more of fruit annually, and this finds a ready market at the canning factories. The Celeste is the common variety, and the demand for the fruit at 4 cents a pound is far in excess of the supply. Oranges are grown along the Gulf coast, but even there the winters are occasionally so cold as to make them unprofitable.

Oranges are being planted extensively along the Gulf coast, especially the Satsuma, a kid-glove variety of Japanese origin, which has proved hardy, producing regular and abundant crops, the trifoliata being used as a stock for grafting. This variety of orange has withstood cold as low as 12° above zero. It is found that it grows and bears equally well, if not better, on the Gulf coast of Mississippi than in its native home. Several million trees of this orange have been planted in the last ten years, and the output has attained to considerable proportions.

Pecans of the paper-shell kind are cultivated extensively throughout the state, especially in the southern tier of counties, Jackson, Harrison and Hancock fronting immediately on the Gulf. Some years ago, some exceedingly large pecans of very thin shell and of a delightful flavor were found growing in Jackson County in the vicinity of Ocean Springs, and Pascagoula in Jackson County. These nuts attracted considerable attention and many nurserymen on the Gulf coast grafted from these varieties and extensive planting of them was immediately begun. Many large groves are now established on the coast, especially in Jackson County, and the trees bear enormous crops, some of them reaching a capacity of 225 pounds per annum. Grafting-wood from these trees has been taken extensively to other states, in which the soils are adapted to this nut. There are many groves along the Gulf coasts of Missisisippi now of 100 to 1,000 acres and the industry promises to be very extensive and profitable to those who engage in it. There was shipped from the Pascagoula district in 1914 more than 200,000 pounds of paper-shell pecans and half as many from the Ocean Springs district.

Grapes grow and bear as well as it is possible for them to do in any part of the country. The long season for growth develops very strong vines which are never injured by the cold of winter, and the latest ripening sorts have ample time for maturing. The early varieties ripen about June 20 in the Gulf coast district, and about July 10 in the northeastern district, and nearly all the crop is gathered by August 1. This early ripening of the fruit enables the grower to secure high prices for his early shipments, but a crop which matures in the heat of midsummer cannot be kept profitably, even in cold storage, but must be marketed at once, regardless of price. Champion, Ives, Delaware, Niagara, Perkins and Herbemont are among the more popular varieties. The Scuppernong (*Vitis rotundifolia*) is a valuable native grown in all parts of the state for home use and for the manufacture of wine, but is not a shipping variety.

Among the small-fruits, strawberries are the most important, being grown by thousands of acres. They are grown more extensively in the central district than elsewhere, though there is a considerable acreage in the northeastern district also. In the Gulf coast district the plants grow well and bear abundantly. Klondyke and Lady Thompson are the favorite varieties. Shipments begin about the first of April, and the bulk of the crop is gathered in the next six weeks, though occasional shipments are made in every month of the year.

Blackberries and dewberries grow spontaneously in all parts of the state and have proved profitable in cultivation, the Lucretia, Dallas and other hybrids being the favorite varieties. Neither currants nor gooseberries do well in any part of the state, as they make a new growth and come into bloom soon after the fall rains begin, and soon become so weakened as to be worthless. Raspberries do well when planted on soils containing sufficient moisture, but are seldom grown for market excepting in the northeastern district. Turner is the favorite variety, and the blackcaps are rarely seen.

The growing of early vegetables for northern market is followed more extensively and is more generally profitable than is the growing of fruits. Field plantings of radishes, peas and other hardy sorts begin in January. Shipments begin by the first of March and continue until the melon crop is harvested in July. The first crop of Irish potatoes, mostly Early Ohio and Triumph, is ready for market in May, and in August a second crop is often planted which matures in November, when it finds a ready home market, or is left in the ground until early spring, when it is placed on the northern markets as "new potatoes just received from Bermuda," and brings a high price. The second crop, however, is uncertain, as it is difficult to secure a prompt growth if seed from the early crop is used, and it is often impossible to secure northern seed so late in the season. Sweet potatoes are grown in all parts of the state, and are shipped from July until March. Asparagus is a profitable early crop which is grown largely in the central district, and seems wholly free from rust or other diseases. Rhubarb is unable to endure the heat of the long summer, and the roots soon decay. Beans, beets, cabbages, peas, radishes and turnips are all grown so largely as to be shipped in carload lots from a number of towns in the northeastern and central districts. The crop grown more widely than any other is the tomato, which is grown in all parts of the state, and which is shipped by the carload to all parts of the country from Boston to St. Paul, Omaha and Denver. Many single growers ship by carlots, and in June from ten to twenty cars are shipped daily from Crystal Springs, which is south of Jackson, with nearly as many from Madison Station and Booneville, besides smaller shipments from many other points. In 1911 more than 1,000 carloads of vegetables were shipped from Crystal Springs, the shipments ranking in importance in the order named, viz., tomatoes, cabbages, beans, carrots, peas, turnips, beets.

From the central district, shipments are made about as follows: Beans, May 10 to June 10; beets, April 20 to June 15; cabbage, May 1 to June 5; carrots, April 20 to June 10; melons (Gem), June 20 to July 20; peaches, June 1 to August 1; peas, March 25 to April 25; potatoes, Irish, May 10 to June 15; radishes, March 1 to April 15; squash, summer, May 15 to June 15; strawberries, April 1 to May 10; turnips, March 20 to May 15; tomatoes, May 25 to July 4; watermelons, July 1 to August 1.

There are a number of canneries in the state, the most successful being those at Booneville and Biloxi, but ordinarily growers find it more profitable to ship products to northern markets than to sell at prices which canners can afford. Partial reports from other points indicate that shipments, in carlots, amount to not less than 8,000 cars annually, in addition to nearly as much more which is shipped in small lots. The northeastern and central districts ship principally to northern markets, while the Gulf coast district finds its markets in Mobile, New Orleans, and on the many foreign vessels loading in Ship Island harbor. Nearly the entire business has been developed in the last twenty-five years, and each succeeding year shows a marked increase in its volume. New localities are being opened, the work is constantly better organized, and, with the increase of the business, the markets are becoming more steady, prices more uniform, and the profits more satisfactory than in the early days. The business has by no means reached its full development, and will not do so for years to come.

Among the men who have been influential in establishing horticultural industries in Mississippi was the late W. R. Stuart, of Ocean Springs, to whom much of the present volume of the pecan interest is due, a development that promises much for the state.

Public-service agencies for horticulture.

The land-grant college of Mississippi was established at Agricultural College in 1880. The institution is near Starkville, in the northern half of the state. At the present time (1915) there are four members of the horticultural staff.

The central Experiment Station is located at Agricultural College and there are three branch stations at Holly Springs, McNeil, and Stoneville. Two of these branch stations are carrying on experimental work in horticulture. Seventeen horticultural bulletins have been issued.

The nurseries of the state are inspected each year by the entomologist of the Experiment Station.

Statistics (*Thirteenth Census*).

The approximate land area reported in 1910 was 29,671,680 acres, of which 62.5 per cent is in farms. The improved land in farms, numbered 9,008,310 acres; the woodland in farms, 7,883,558 acres; and the other unimproved land in farms numbered 1,665,665 acres. The total number of farms in Mississippi in 1910 was 274,382. The number of acres in the average farm was 67.6. [The total area of Mississippi is 46,865 square miles, by the latest calculations.]

The leading agricultural crops in Mississippi are cotton (including cotton seed), cereals, hay and forage, and sugar crops, and also forest products of the farm. Cotton is by far the most important of the farm crops. The acreage increased from 2,897,920 in 1899 to 3,400,210 in 1909, when the value of the production was $96,353,433, or 65.4 per cent of the total value of all crops. Cereals decreased in acreage from 2,372,065 in 1899 to 2,270,503 in 1909, when the value of the products was $26,864,772. Hay and forage increased in acreage from 99,261 acres in 1899 to 229,705 in 1909, an increase of 131.4 per cent, when the value of the products was $3,363,647. The value of the products from 42,731 acres devoted to sugar crops amounted to $1,851,178. The value of forest products of farms in 1909 was $6,602,943, as compared with $3,023,626 in 1899. Among crops with no acreage reports, the miscellaneous crops had a value in 1909 of only $5,740 and in 1899 of $2,845; seeds had a value of $1,047 in 1909 and $1,185 in 1899.

Horticultural crops produced are fruits and nuts, small-fruits, vegetables, including potatoes and sweet potatoes and yams, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $1,579,752, as compared with $497,779 in 1899. The acreage occupied by small-fruits decreased from 1,549 in 1899 to 836 in 1909, when the production was 1,407,301 quarts, valued at $107,171. In 1909 the total acreage of potatoes and other vegetables was 125,610 and their value $9,483,576. Excluding potatoes and sweet potatoes and yams, the acreage of vegetables was 61,223 and their value $5,868,275. Flowers and plants and nursery products increased in acreage from 243 in 1899 to 572 in 1909, when the value of the production was $175,267, as against $58,212 in the year 1899.

The production of orchard-fruits in 1909 was 1,634,305 bushels, an increase of 167.5 per cent over 1899. Peaches and nectarines, and apples produced most of this quantity. The number of peach and nectarine trees of bearing age in 1910 was 1,726,298; those not of bearing age, 724,895. The production in 1909 was 1,156,817 bushels, valued at $925,288. The number of apple trees of bearing age in 1910 was 427,652; those not of bearing age, 425,323. The production in 1909 was 265,841 bushels, valued at $213,714. Pears and plums and prunes were of relative importance in 1909, there being produced 101,288 bushels of pears, valued at $96,777, and 101,974 bushels of plums and prunes, valued at $79,971. There were also produced in Mississippi, in 1909: 2,819 bushels of cherries, valued at $3,749; 2,277 bushels of apricots, valued at $2,510; 2,725 bushels of quinces, valued at $2,863; and 564 bushels of mulberries valued at $634.

The grape-vines of bearing age in 1910 numbered 77,012; those not of bearing age, 34,870. The production decreased from 1,070,625 pounds in 1899 to 760,563 pounds in 1909, when it was valued at $44,262.

The total production of nuts in 1909 was 866,504 pounds, valued at $90,885. Pecans are by far the most important of the nuts, producing in 1909, 637,293 pounds, valued at $79,936. In addition, 66,492 pounds of Persian or English walnuts were produced, valued at $6,949, and 151,406 pounds of black walnuts, valued at $3,700.

Tropical fruits were produced in 1909 to the value of $119,129. Figs are the most important, there being produced in 1909, 1,949,301 pounds of figs, valued at $107,609. Oranges are apparently increasing since the number of orange trees of bearing age in 1910 was 10,452, and those not of bearing age, 38,637. The production of oranges in 1909 was 3,779 boxes, valued at

$8,684. The number of grapefruit (pomelo) trees of bearing age in 1910 was 1,001; those not of bearing age 1,978. The production in 1909 was 1,368 boxes, valued at $2,345.

Strawberries are by far the most important of the small-fruits in Mississippi, although the total acreage of all small-fruits decreased from 1,549 in 1899 to 836 in 1909. Considering strawberries, the acreage decreased from 1,383 in 1899 to 772 in 1909, when the production was 1,345,013 quarts, valued at $101,882. The other small-fruits produced were: 53,735 quarts of blackberries and dewberries, valued at $4,531; 7,806 quarts of raspberries and loganberries, valued at $673, and minor quantities of currants and gooseberries.

The acreage of sweet potatoes and yams increased from 38,169 in 1899 to 56,045 in 1909, when the production was 4,427,988 bushels, valued at $3,073,290. The acreage devoted to the production of peanuts increased from 5,853 in 1899 to 13,997 in 1909, an increase of 139.1 per cent. The production in 1909 was 284,791 bushels, valued at $317,236. The acreage devoted to potatoes increased from 6,370 in 1899 to 8,342 in 1909, when the production was 644,742 bushels, valued at $542,011. Of the other vegetables grown in Mississippi, the more important were: 3,651 acres of tomatoes, valued at 401,984; 1,396 acres of cabbage, valued at $98,244; 1,794 acres of watermelons, valued at $86,973; 1,052 acres of green beans, valued at $43,925; 194 acres of radishes, valued at $30,216; 435 acres of green peas, valued at $18,342; and 234 acres of turnips, valued at $15,987. Vegetables of minor importance were asparagus, beets, cantaloupes and muskmelons, carrots, sweet corn, cucumbers, lettuce and onions.

The acreage devoted to the production of flowers and plants decreased from 62 in 1899 to 39 in 1909. The total area under glass in 1909 was 216,937 square feet, of which 201,622 were covered by greenhouses and 15,315 by sashes and frames. The value of the flowers and plants produced in 1909 was $100,321.

There was a marked increase in the acreage devoted to nursery products—from 181 in 1899 to 533 in 1909, an increase of 194.5 per cent. The value of the nursery products in 1909 was $74,946, as compared with $31,305 in 1899.

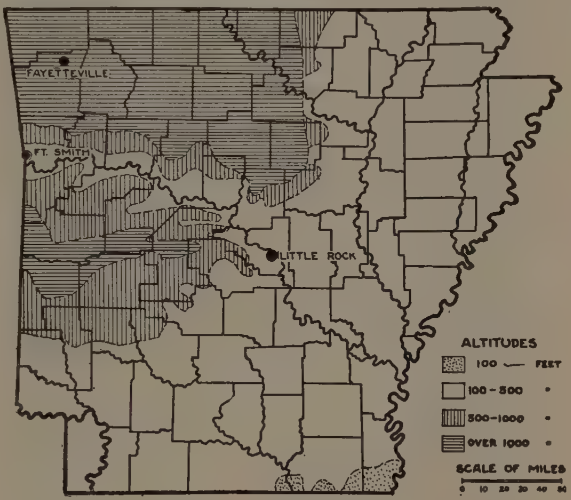
S. M. Tracy.
F. H. Lewis.

WEST SOUTH CENTRAL STATES.

Arkansas.

Differences in altitude give the state of Arkansas (Fig. 2520) two general types of climate and agriculture. The northwestern two-fifths of the state has a north-temperate climate and is adapted to practically all the crops usually grown some hundreds of miles northward. In the southeastern three-fifths of the state, climatic conditions are subtropical, cotton being the leading farm crop, while corn and rice are also grown extensively. A line drawn from the northern part of Sevier County to Arkadelphia, thence past Little Rock, a little to the northward, and thence to Mammoth Springs in northern Arkansas separates in a general way the two divisions. The division line represents a general elevation of 500 feet. Northwestward the general elevation soon increases to 1,000 feet, with here and there points and ridges rising a few hundred feet higher. The Boston Mountain, a ridge running eastward along the southern border of Washington County and extending into Searcy County, presents an elevation of about 2,000 feet. This barrier has a marked effect on the climate north of it, making the conditions like those of regions many miles farther north. Southward the slopes descend into the Arkansas Valley and into a truly southern climate. Between Fayetteville and Van Buren, a distance of about 60 miles, there is a difference of ten to twelve days in the earliness of the season. In Pope County, Mount Magazine (height, 2,850 feet) is said to be the highest point between the Alleghany and Rocky Mountains. The Ozarks of northwestern Arkansas enter the state from Oklahoma and Missouri. In central-western Arkansas, the broken elevated area consisting of a series of ridges running in an easterly and westerly direction is known as the Ouachita Mountains. In general, the main hills or ridges and valleys in the hill country of Arkansas have an easterly and westerly direction. They represent the work of erosion, although the Ozark region as a whole is part of an uplift and one of the oldest parts of the continent.

The surface in general of the highland is rolling, partly tableland, rough in places with small prairies here and there. The average elevation of the Ozark portion of the state is about 1,000 feet above sea-level. Some of the valleys are narrow, others broad, miles in extent and of great fertility. On some of the hills the soil is thin and poor, sometimes very rocky; again it is fertile and deep. North slopes, as a rule, are more fertile than the southern. There are various types of soil from sandy to clayey loam, cherty soils and the rich brown loam known as "pawpaw" soil with redclay subsoil overlying limestone. Clarksville silt loam and Clarksville stony loam are common types of upland soil in northwestern Arkansas. The valleys also range from sandy alluvial loam to clayey and heavy black soils very rich but sometimes needing drainage. In their natural condition the hills and valleys are covered with the various kinds of forest growth characteristic of the northern woods, contributing to the mildness and healthfulness of the climate.



2520. Arkansas, to show horticultural parts.

The winters are short and summers long. The mean temperatures for January and July, respectively, at Fayetteville are 37.59° and 77.03°, and at Little Rock, 40.8° and 80.3°. The rainfall is ample and ordinarily well distributed throughout the year. The average for the state is 50.5 inches. It is somewhat less in northwest Arkansas, being 45.6 at Fayetteville and reaching 63.2 inches at Hot Springs. Irrigation is not necessary. Proper tillage may be made to conserve the supplies of moisture sufficiently for bountiful yields under all ordinary conditions. The average snowfall in the hill country is nine inches; southward it varies from three to five.

The southeastern half of the state is in reality a part of the low level and fertile Atlantic coastal plain and is similar to Louisiana. The surface is rolling, varying from 100 to 500 feet in elevation. Much of the land, especially along the Mississippi, is low-lying and subject to inundation from the Mississippi River. In this part of the state are numerous lakes, bayous and swamps. There are about 6,000,000 acres of these lower-lying lands, of abounding fertility, needing only drainage to make them among the most productive in the world. Along the lower valley of the Arkansas the soil grades into black sandy and "buck-shot," the richest soils of the state. Along the southern border of the Ozarks and Ouachita elevations is a belt which, while belonging to the highland area, represents an intermediate zone between that and the lowland country of the state. It is especially adapted to growing peaches.

In the lower parts of the state there are also locations affording air-drainage and soils suited to commercial peach-growing. On the whole, however, this region will be found best adapted to truck-farming. Some crops, like onions, spinach, and kale, may be planted here in the fall months. Figs, Japanese persimmons, pecans, and some varieties of grapes offer good opportunities, while selected varieties of most north-temperate fruits may be grown successfully for home use.

The principal horticultural industry is the production of winter apples. The leading counties are Benton, Washington and Madison in northwest Arkansas. Transportation facilities have been an important factor in stimulating development. Other counties in the Ozarks equally good for fruit lack railroad transportation and for this reason are less developed horticulturally. Quantities of second-grade apples go to driers or are converted into vinegar. Some fifty-six varieties of apples have originated in Arkansas, some of them being of great commercial value, not only in this state, but elsewhere. A recently introduced variety is the King David which originated in 1903 near Durham, Washington County. Formerly about 95 per cent of plantings were Ben Davis. More recently there has been a noticeable tendency to plant varieties of better quality. Leading winter varieties of apples at present are Ben Davis, Gano, Black Ben, Winesap, Jonathan, Arkansas, York Imperial, Grimes Golden, Ingram, Givens, Collins, Beach, Stayman's Winesap, Delicious and King David.

For the past several years, increased attention has been given summer apples. These are grown with success southward as well as in the hill country. Leading varieties are Maiden's Blush, Duchess, Horse, Buckingham, Summer Champion, Red June, Red Astrachan and Yellow Transparent. While an excellent market variety, the last is very subject to "twig-blight," especially in the lower part of the state.

Second only to the apple-orchard interests is the commercial production of peaches. To S. B. Wing and his brother belong the credit of having shipped the first carload of Elberta peaches out of Arkansas. Thus began the commercial peach industry which has assumed such vast proportions in the state in the past ten years. The Elberta is not so reliable in the higher districts as in some of the counties lying along the southern slopes of the Ozarks and Ouachita Mountains. Here the air-drainage, soil and other conditions are such as to be especially favorable for almost annual crops and peaches of splendid color and quality. The record in Crawford County is about seven crops in ten years. In 1911, orchards in Pike and Sevier counties were practically the only peach orchards in the United States which produced crops. The fruit from these orchards brought probably the highest prices on record for peaches in carlots. The two first cars shipped to New York brought $2,080 a car, and later averaged $1,500 a car. Extensive peach-orchard interests have in recent years developed rapidly in Pike County. Commercial plantings are chiefly Elbertas. The shipping season follows that of Texas and Georgia when the markets are slack, which proves to be a great advantage. Very early peaches for shipment have not proved profitable. Northwest Arkansas will have to find a variety hardier in bud than Elberta. Champion, Carman, Slappy, Belle of Georgia, Madison County Mammoth, General Lee, Crosby, and possibly some others are much more reliable varieties for northwest Arkansas, although not so satisfactory for shipment as the Elberta.

Pears are not receiving much attention on account of their susceptibility to "fire blight." Kieffer, Garber, LeConte, Winter pear (Sand pear), Seckel and Duchess are among the varieties least susceptible to blight.

Cherries are of comparatively little commercial importance at present. The sour cherries are the most satisfactory. There are but few large cherry orchards in the Ozark region. Leading varieties are English Morello, Early Richmond, Montmorency and May Duke.

Plums were represented in 1909 by 731,276 bearing trees. Leading varieties are Burbank, Red June, Gold, Wild Goose, Poole's Pride, Damson, German Prune.

Pecan trees are found growing wild in abundance in the cotton section of the state, especially in river-bottoms. The interest in pecans has rapidly increased in the past three or four years. Some recent single plantings contain as high as 400 acres of grafted trees. Some pecans are being grafted on the common hickory. Such trees are known to thrive and bear as well as on their own roots. The Schley and Moneymaker are known to do well in the state.

English walnuts are receiving practically no attention. How well they would succeed remains to be determined. The black walnut and hickories are common growing wild and occasionally large sweet chestnut trees are found, although the chinquapin is much more frequent. Some attempts have been made to use the latter as a stock for the sweet chestnut with good success, especially in the case of the large Japan chestnut.

Grapes thrive in Arkansas. The output of vineyards at present is used chiefly for wine. The Cynthiana, a variety of native origin, is the most highly valued wine-grape. Saline County some years ago was an important grape- and wine-producing county, the industry being conducted chiefly by German citizens. Owing to state laws against the sale of alcoholic drinks, the industry declined. At present the law allows the producer to sell native wine in quantities of not less than five gallons, not to be consumed at the place where sold, nor sold in the localities having the "five-mile" law or local prohibition. The bottling of unfermented grape-juice offers excellent opportunities. Grapes receive special attention at Tontitown, Altus, Silver Springs, Highland and other points. In the past few years extensive plantings have been made at some points southward. Joseph Bachman, of Altus, has been the originator of several varieties of great merit (Sunrise, Banner, Stark's Star and others).

Strawberries have been commercially grown in a large way for many years in northwest Arkansas, as well as in counties southward. George P. Murrell, of Austin, shipped the first crate of strawberries to St. Louis some forty years ago. Mr. Bauer, of Judsonia, was also one of the pioneer growers. About 1893, C. H. Gregory commenced the strawberry industry in Crawford County, and it has extended northward along the Frisco and Kansas City Southern Railroads in northwest Arkansas and has become one of the most important branches of fruit-growing in the Ozarks. Leading varieties at present are Excelsior, Klondyke and Aroma.

Blackberries are canned extensively and grown throughout the state for home use. While shipped to some extent, they are not important as a commercial crop. Currants seem not to thrive. Of gooseberries, Smith and Houghton only prove satisfactory, and these only in the mountain region.

In the west where irrigation is necessary, orchards are planted in the valleys. In the Ozarks where the rainfall is ample for the needs of crops, apple and other fruit trees are planted mainly on the slopes and higher lands where, owing to air-drainage, the fruit is less subject to damage by spring frosts than in the valleys. Although there is a critical frost period the latter part of April, properly located and cared-for orchards escape injury except occasionally. A typical Ozark orchard of 40 acres under good care has borne during the past seventeen years fourteen good crops of apples, two light crops, and has had but one total failure. Another apple orchard has had in seven years six fair to large crops and but one very light crop. Experiments indicate that orchard-heaters are not necessary in well-located and well-cared-for apple orchards in the Arkansas Ozarks except occasionally, or at intervals of four or five years. Like spraying, it is a kind of insurance and some growers have provided heaters for a part of their orchards as a safeguard against the occasional frost-damage. The higher parts of the state are not so well suited to the Elberta peach as lands southward on the southern slopes of the highlands where the elevation ranges from 300 to about 800 feet. In both sections peaches are damaged more frequently by winter injury to the flower-buds than by spring frosts. Orchard-heaters are practical and successful in raising the temperature in the orchard sufficiently, under usual conditions, to save the crop, but careful attention to location, air-drainage, and proper care are more important.

Many of the fruit and other trees planted are purchased from nurseries outside the state, and planters have suffered frequent loss from trees proving untrue to name, infested with San José scale and diseased by crown-gall. In 1911 only twenty nurseries in the state called for official inspection. The growing of ornamentals is represented in the state by a few nurseries only. There is an extensive greenhouse establishment at Little Rock and several smaller establishments which at other points supply the local demand. The forcing of flowers and vegetables under glass receives but little attention and only for the supply of local trade at a few of the large towns.

Tomatoes are grown extensively throughout the state; string beans also, for shipment and canning. Asparagus thrives throughout the state. Onions have not received much attention commercially, probably because Texas has the advantage in earliness and produces such large quantities. Rhubarb is grown and shipped to a limited extent in northwest Arkansas. It does not succeed southward. Melons are an important commercial crop. Both the watermelons and cantaloupes grown are of high quality. Many hundreds of carloads are shipped northward in their season, from a few shipping-points. The Arkansas Gems reach the markets some weeks in advance of the well-known Colorado melons. Watermelons evidently were introduced into the state at a very early day, since it is said that the Indians treated to watermelons the remnants of La Salle's band when they were passing through the state in 1687.

Irish potatoes are grown extensively throughout the state. Red Bliss is the leading variety grown. Early Ohio, Irish Cobbler, Sunlight and Burbank are also grown. In 1909, counties leading in production were: Sebastian, 101,328 bushels; White, 91,231 bushels; Washington, 67,739 bushels; Pulaski, 62,253 bushels; and Crawford, 46,492 bushels.

Sweet potatoes find congenial conditions in all parts of the state and yield well under fair treatment, yields ranging from 200 to 600 bushels an acre.

Many of the orchard-owners have evaporators for utilizing the second-grade apples. Towns in the several orchard districts have one to several evaporating plants of large capacity which make a business of producing evaporated apples. Culls, cores and peelings are converted into vinegar.

Before the National Pure Food Law was passed (1906), little cider vinegar was produced in a commercial way. At present there are large and well-equipped plants at Rogers, Siloam Springs and other points. There are also large apple-brandy distilleries at Rogers and Bentonville, the latter being the largest in the world.

Home canners have become common in connection with fruit-growing and truck-gardening in order to utilize surplus fruit for home use and local markets. There are large well-equipped central plants at Prairie Grove, Bentonville, Fayetteville, Decatur and some other points.

Public-service agencies for horticulture.

Horticultural instruction is given as a part of the Agricultural College work at the State University at Fayetteville. It is also provided for in each of the four Agricultural High Schools by legislative enactment in 1907, and opened for instruction two years later. These schools are located at Russellville, Jonesboro, Monticello, and Magnolia. Extension work is carried on by the college.

There are local horticultural societies at a number of points where such interests are important or being developed. Springdale and Bentonville have very successful societies. The latter has been in existence for many years, and is well known beyond the confines of the state for its useful work.

Coöperative fruit-marketing associations exist at most of the important shipping-points. These, when independent, compete with each other more or less by shipping to the same markets. The Ozark Fruit-Growers' Association is a general organization formed in 1904 to handle the output of the numerous local associations of the Ozark region.

The Arkansas State Horticultural Society was organized in 1879. Among the original organizers, S. H. Nowlin, W. S. Thomas, E. F. Babcock, Jos. W. Vestal, W. K. Tipton have all rendered valuable services to horticulture. Judge I. B. Lawton, for years secretary of the Benton County Horticultural Society, also deserves special mention. Recently the fruit-growers of northwest Arkansas have organized "The Northwest Arkansas Fruit Growers' Society," as a branch of the State Society. The sweet potato growers have also organized a society as a branch of the State Society.

Statistics (*Thirteenth Census*).

The approximate land area is 33,616,000 acres of which 51.8 per cent, or 17,416,075 acres, are in farms. The percentage of the farm land that is improved is 46.4, or 8,076,254 acres. The farm land in woodland is 8,511,510 acres, and the unimproved land in farms numbers 828,311 acres. There are 214,678 farms in the state, the average size of which is 81.1 acres. [The total area of Arkansas is 53,335 square miles.]

The leading agricultural crops are cereals, hay and forage, cotton, and forest products. In 1909 the value of the cereals was $31,262,922. The acreage was 2,564,898 in 1909, a decrease of 13.9 per cent since 1899, when it was 2,980,684. The acreage of hay and forage, in 1909, was 435,915, an increase of 82.1 per cent over the acreage in 1899, when it was 229,426. The value of the hay and forage products in 1909 was $4,887,139. In 1909 cotton contributed 52.9 per cent of the total value of all crops. The value of cotton products in 1909 was $63,155,683. The acreage of cotton in 1909 was 2,153,222, as compared with 1,641,855 in 1899, an increase of 31.1 per cent. The value of the forest products in Arkansas for 1909 was $6,914,262.

The leading horticultural crops are fruit, vegetables, small-fruits, nuts, flowers, plants and nursery products. In 1909 the value of the fruits and nuts was $3,142,891; of vegetables, $7,641,102; of small-fruits, $601,722; and of flowers, plants and nursery products $352,000.

The principal orchard-fruits are apples and peaches, which in 1909 produced more than one-half of the total quantity of orchard-fruits. The number of apple trees of bearing age in 1910 was 7,650,103; the apple trees not of bearing age numbered 3,940,089. The quantity produced in 1909 was 2,296,043 bushels, valued at $1,322,785. The peach trees that were of bearing age in 1910 numbered 6,859,962; those not of bearing age, 2,884,927. The production of peaches was 1,901,647 bushels, valued at $1,502,996. The production of the other orchard fruits and their value in 1909 is as follows: pears, 37,547 bushels, valued at $38,140; plums and prunes, 194,649 bushels, valued at $137,003; cherries, 5,993 bushels, valued at $8,424; apricots, 1,067 bushels, valued at $1,091; quinces, 680 bushels, valued at $751.

Of nuts the pecans and black walnuts were the most prominent, there being 249,955 pounds of pecans produced in 1909, valued at $17,603; and 514,273 pounds of black walnuts, valued at $7,795. In 1910, the number of pecan trees was 13,958, while the number of black walnut trees was 9,104. In addition to the pecans and black walnuts, Arkansas produced, in 1909, 15,436 pounds of Persian or English walnuts, valued at $1,384, and 3,330 pounds of almonds, valued at $622.

The only tropical fruit of any significance is the fig, of which 80,707 pounds were produced in 1909, valued at $5,953.

The production of grapes in 1909 amounted to 2,593,727 pounds, valued at $97,985, a decrease from 3,621,100 pounds, valued at $104,803 in 1899.

Of the small-fruits, strawberries are by far the most important, with blackberries and dewberries ranking next. The total acreage of small-fruits in 1909 was 8,032; and in 1899, 10,819, a decrease of 25.8 per cent. The production in 1909 was 8,965,572 quarts, as compared with 14,098,000 quarts in 1899. The acreage of strawberries in 1909, was 7,361, producing 8,259,240 quarts, valued at $549,041. The acreage of blackberries and dewberries was 525; the production 587,977 quarts, valued at $40,843. The production of other small-fruits in 1909 are as follows: 96,414 quarts of raspberries, valued at $9,766; 18,168 quarts of gooseberries, valued at $1,630; 3,201 quarts of currants valued at $390; and 288 quarts of cranberries, valued at $26.

In 1909 the total acreage of potatoes and other vegetables was 112,358 and their value $7,643,102. The production from 29,719 acres of potatoes in 1909 was 2,096,893 bushels, valued at $1,439,991. The production from 22,388 acres of sweet potatoes and yams for the same year numbered 1,685,308 bushels, valued at 1,359,669. Other vegetables, excluding potatoes, sweet potatoes and yams, occupied an area of 60,251 acres in 1909, compared with 45,355 acres in 1899, and the value of their products was $4,843,442 in 1909, as compared with $2,245,587 in 1899. The more important of these vegetables in order of value are watermelons, cantaloupes and muskmelons, tomatoes, turnips, cabbage and onions.

The value of the flowers and plants in 1909 was $153,421. The area under glass, devoted to this industry, was 235,134 square feet, of which 224,150 square feet were covered by greenhouses and 10,984 square feet by sashes and frames. The increase in the value of the flowers and plants was 494 per cent, from 1899 to 1909.

The nursery products, in the period from 1899 to 1909 decreased 39.2 per cent in acreage but increased 51.5 per cent in value. The acreage in 1909 was 528; in 1899, 868. The value of the nursery products was $198,579 in 1909, and $131,045 in 1899.

Ernest Walker.

Louisiana.

Louisiana (Fig. 2521) is situated at the extreme lower limit of the great Mississippi system, bordering on the Gulf of Mexico. These bodies of water have an important bearing upon the climate, and make it possible to grow some of the subtropical fruits. The prevailing wind is from the south, somewhat cool and always laden with moisture, and the southern part of the state, being only about 30 feet above the sea-level, receives the heaviest rainfall, 70 inches, while the northern part which is more elevated and farther from the Gulf, has an annual rainfall of 45 to 50 inches. This, as a rule, is well distributed throughout the state, the seasons of greatest drought being early spring and early autumn. The highest recorded summer temperatures run from 98° along the Gulf coast, to 102° in the northern part of the state, while the average winter temperature is 56°.

Occasionally a northwestern blizzard reaches down into the state, causing a heavy fall in temperature, accompanied with sleet, and once in a long time, snow. The lowest recorded temperature on this account was 9° in 1895, and 13 inches of snow. This was an occurrence unheard of by the oldest inhabitants. These occasional blizzards have forced the culture of tropical fruit down to the section immediately bordering on the Gulf. As the soil has such an important bearing upon the character of the fruit, a rough classification of the different kinds is here given.

1. The sandy hills and uplands occupy the northwestern part of the state along with a section in the eastern part, south of the state of Mississippi, constituting about one-half the total area of the state. The lands are characterized by sandy soils, with pine and oak forests, and produce the best stone-fruits and berries.

2. The bluff lands occupy a broken strip, running parallel with the Mississippi, from 30 to 50 miles from its western bank, and disappear near the Gulf in what are known as "islands," such as "Avery's Island" and "Jefferson's Island." There is also another section of these lands on the east bank of the river immediately south of the Mississippi state line. These lands are characterized by a yellow clay loam, very fertile, and by forests of magnolias, gums, oaks, and the like. They produce some of the stone-fruits well, and an abundance of pecans, berries and figs.

3. The prairie lands occupy a part in the central southwestern part of the state, are treeless, low and are also known as rice lands. The soil is poor but improves with cultivation, and gradually the planting of figs, pears, peaches, plums and grapes have been extended.

4. The alluvial lands make up all the other parts of the state not mentioned, including the river-bottoms. The soil is generally dark, ranging from black to light red, very fertile and abounding in an abundant growth of timber. They produce the heavy yields of cotton and corn in the northern part, and the sugar-cane, oranges, lemons, persimmons, figs and bananas, as well as other tropical fruits, in the southern part.

5. The pine flats are found in the western and extreme eastern parts of the state where the hill lands merge into an extended area of level lands which in turn are gradually depressed to the Gulf marshes. This area is naturally wooded with dense forests of long-leaf pine. The soil is not very fertile, but when properly drained and fertilized becomes an excellent soil for strawberries and some small-fruits. Trucking is also highly developed in some parts of the pine flats.

The leading varieties of vegetables are grown in every section of the state, and the home garden furnishes an abundant supply during all seasons of the year, under proper management. Those vegetables most popularly grown for home consumption are as follows: Asparagus (on the sandy soils only), artichokes (both Globe and Jerusalem), beans, beets, cabbage, carrots, collards, corn, cress, cucumbers, cashaw (pumpkin), endive, egg-plants, kohlrabi, leek, lettuce, melons, mustard, okra, onions, parsley, peas, peppers, Irish potatoes (two crops), sweet potatoes, radishes, spinach, tomatoes, turnips and rutabagas. Occasionally there is found the vegetable pear (*Sechium edule*), martynia, brussels sprouts, celery, chervil, garlic, kale, salsify, parsnips, cauliflower, and field pumpkins. Most of these vegetables may be sown several times during the year. Celery and cauliflower, however, are sown early in August in order to mature by the Christmastide.

The commercial truck sections are found in various sections of the state. Along the Illinois Central Railroad a direct line to Chicago from New Orleans, which runs through the warm sandy pine lands, the most extensive truck-farms are to be seen. The vegetables grown are radishes, carrots, beans, cabbage, Irish potatoes, tomatoes, peppers, eggplants, and cauliflower. Hundreds of carloads of these vegetables are sent to the central, northern, and eastern markets during the months of March, April, and May. This section is also one of the largest producing areas of strawberries in the United States. Tangipahoa Parish alone has over 15,000 acres and ships 1,200 to 1,500 or more cars annually. The Klondyke is the variety universally planted. It is a wonderful shipper and is found on the market as far east as Boston, as far north as Canada, and even as far west as Seattle. The value of this crop alone runs into millions of dollars.

On the same railroad, a little above New Orleans, is Kenner, which is noted in the North for its "bunch crops," such as shallots, carrots, beets, turnips, radishes, mustard and spinach. The rich alluvial lands of this section produce these crops to perfection. They are packed in sugar barrels with crushed ice. Quotations on Kenner vegetables are usually above the average on account of their excellent quality and solid pack. Cabbage, lettuce, and snap beans are also extensively grown and shipped from this point.

The largest truck section of the state is found in the vicinity of New Orleans. This city is also the distributing point for large quantities of vegetables grown along the river and bayous southward. Thousands of cars move over the many trunk lines to the North, East, and West. Shallots, turnips, beets, radishes, carrots, mustard, and spinach are extensively grown and shipped in sugar barrels; also lettuce, endive, cabbages, cucumbers, eggplants, peppers, beans, and many other vegetables adapted to the alluvial soils. In this section are found the large commercial orange groves of the state. (See *Orange-culture in Louisiana*, p. 2374.)

Along Bayou Lafourche from Donaldsonville to Lockport, Creole onions are extensively grown as well as Irish potatoes. This section is beginning to plant large quantities of Snowball cauliflower.

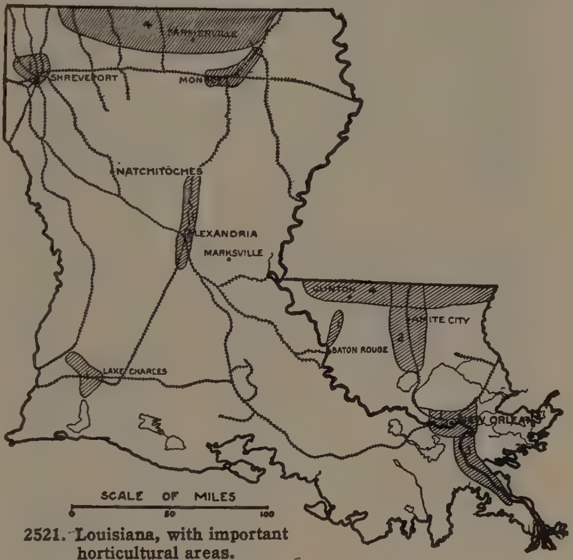
Alexandria is the center of the Irish potato industry. Trainloads of early potatoes from this point move northward during late April and early May.

Early tomatoes are extensively planted at Norwood along the Yazoo & Mississippi Valley Railroad. The warm rolling sandy loams of this section produce a very early fruit of high quality. A very successful coöperative canning factory is being operated to utilize surplus vegetables that cannot be shipped. Hundreds of acres of Cayenne peppers are grown in this vicinity and the product is dried and ground by a local factory.

The varieties of these vegetables grown for the northern markets are as follows: The Acme and Beauty tomatoes, the Chartier radish, the New Orleans Market eggplant, the Peerless and Triumph Irish potatoes, the New Orleans Market and White Spine cucumbers, the Drumheads, Flat Dutch, Succession, All-Seasons and Nonesuch cabbages, the Italian and Bermuda type of onions, the First-and-Best and Alaska peas, the Early Mohawk and Valentine beans. In the northern part of the state large quantities of Irish potatoes are grown, and oftentimes the second crop is very profitable. The first crop is planted in January or February and harvested in May and June. The seed for the second crop is prepared for planting by special treatment, consisting of gradually exposing the tubers to the light and moisture, which matures them and excites the eyes into growth. As soon as this is accomplished they are ready for planting, which is usually during August. They are harvested in November.

Upwards of 5,000,000 bushels of sweet potatoes are grown annually, the varieties best known being Pumpkin, Nancy Hall, Triumph, Creole, California, Bermuda, Red and Yellow Nansemond, Hayman, Providence, Yellow Jersey, Southern Queen and Vineless. The last variety is one of the most desirable of the newer sweet potatoes.

The culture of fruit, other than oranges and strawberries, has been neglected in great measure. Apples do fairly well only in the northern part of the state, the desirable varieties being Smith, Horse, Red June, Mangum, Early Harvest, Cullasaga and Shannon. Grapes are grown but sparingly, as the long, warm, moist season offers the best conditions under which the grape diseases develop, and the daily rains hinder the use of fungicides; however, in the northern and southwestern parts of the state the following varieties have been found desirable: Champion, Diamond, Eaton, Niagara, Concord, Delaware, Brighton, Sweet Mountain, Herbemont and Jacques. Only the Chinese type of pears is at all grown, as it offers more resistance to the blight than the others. The desirable varieties are LeConte, Kieffer, Smith, Garber, Dai Dai, Golden Russet and Mme. Von Siebold. The European varieties of plums do not succeed, but many of the American and Japanese sorts do well. The desirable varieties are Burbank, Abundance, Satsuma, Kelsey, Chabot, Wild Goose, Robinson and a few others. The fig is grown universally in all sections of the state, the best varieties being Celeste, Brunswick, White Ischia, Magnolia, Angelique, Lemon, Mission and Reine Blanche. The Japan persimmons are being set extensively, using chiefly the Hyakume, Kurokume, Nero Zami, Hachiya, Tsuru and Among. These fruits are large, showy, and will stand transportation well. The Elberta, Sneed, Peen-to (in the south) and Chinese Cling peaches prevail.



2521. Louisiana, with important horticultural areas.

The other fruits, grown in a limited way, are quinces, goumi, blackberries, dewberries, a very few raspberries, pomegranates, bananas, jujubes and pawpaws. There are a few other tropical fruits that are grown only for specimens.

Louisiana abounds in beautiful flowering shrubs and wild flowers. The planting of all kinds of ornamentals is very extensive, roses bloom throughout the season, and the camellia finds a congenial home throughout the southern part of the state. In and around New Orleans the finest ornamental plantings will be found.

Although quantities of nursery stock are grown in Louisiana, many trees, vines, shrubs, cuttings and seeds are brought from other states and from abroad. Several kinds of ornamental plants are imported mainly from Europe, these being handled chiefly by florists in New Orleans. Some florists specialize in growing certain ornamentals, and have built up a large trade with such plants as roses, ferns, orchids and cape jessamines, shipping numbers of them to northern points. Outside of New Orleans, but few florists do anything more than a local business.

Besides ornamental plants, including shade trees, the principal nursery stock produced in the state consists of deciduous fruit- and nut-trees, citrus and fig varieties, and strawberry and grape-vines. Of the deciduous fruits, peach is the leading one, being most generally grown in the northern uplands. While blight is a serious drawback to pear-growing, yet the Kieffer succeeds well on nearly all kinds of soil. Plums and rarely apples are planted in home yards, and sometimes the quince may be seen. The mulberry is a common tree, being valued mostly for its shade, while poultry or hogs are usually allowed to feed on its fruit. Excepting the Japanese walnut and chestnut, of which few trees are known to be of bearing age, the pecan is almost the exclusive nut produced as a crop. Numbers of trees grow practically wild as seedlings, yet the select varieties have been widely planted in both yards and orchards, some of the latter covering extensive areas. The chief nurseries supplying all of these desirable trees and other plants in general are located in the northwestern part of the state. The largest producer of stock owns a place near Shreveport and makes large shipments into adjoining states. A great abundance of young pecan trees have been propagated in nurseries on or bordering the alluvial lands along the Mississippi and lower Red River. The propagation of citrous stock is practically confined to the orange belt comprising the delta and inner coastal lands. In the southwestern section about Lake Charles, the fig has proved to be a profitable crop, the Magnolia making a choice preserve, and nurseries and orchards have been planted with this kind of growth in particular. The pomegranate occasionally occupies a place in the yard also. Strawberry plants are sold by most of the leading crop-producers in Tangipahoa Parish, the main region in which the fruit is grown, but deliveries are generally local. A very few growers in the central and southwestern parts attempt to sell plants from their fields. In the north central sections, grape-culture has showed possibilities of expansion, and the established vineyardists supply stock from their nurseries. Blackberries and dewberries run wild to such an extent that little demand is made for these plants.

Public-service agencies for horticulture.

The Louisiana State University and Agricultural and Mechanical College at Baton Rouge has a department of horticulture and forestry with one professor in charge. The Agricultural Experiment Stations of the University (founded 1887) have one member of the staff at Baton Rouge who conducts the investigations and extension work with truck crops, and another member engaged in horticultural investigations at the North Louisiana Experiment Station, Calhoun.

The Louisiana Industrial Institute, at Ruston, the Southwestern Louisiana Industrial Institute, at Lafayette, and the State Normal, at Natchitoches, as well as the agricultural high-schools, offer horticultural instruction in connection with the general agricultural courses.

The entomologist of the experiment stations inspects the nurseries of the state and imported plants for dangerously injurious insects, diseases and other pests.

Statistics (Thirteenth Census).

In 1910 the approximate land area of Louisiana was 29,061,760 acres. Of this acreage, 35.9 per cent or 10,439,481 was land in farms. Of the land in farms, 5,276,016 acres were improved; 4,316,561 acres were in woodland; and 846,904 was the acreage of other unimproved land in farms. The number of all the farms in 1910 was 120,546, the average acreage being 86.6 to a farm. [The total area is 48,506 square miles.]

The leading agricultural crops of the state are cereals, cotton, sugar crops, and hay and forage. The cereals are by far the most important. In 1909, the acreage devoted to cereals was 1,938,357 and the value of cereal products, $24,786,984, or 32 per cent of the total value of all the crops. The acreage occupied by cotton decreased from 1,376,254 in 1899 to 957,011 in 1909, when the value of the cotton produced was $20,274,747. The acreage of sugar crops increased from 277,903 in 1899 to 331,375 in 1909, when the value of the products was $17,787,054. Hay and forage increased in acreage from 97,136 in 1899 to 180,811 in 1909, an increase of 86.1 per cent, when their value was $2,433,101. The value of the forest products of the farms was $3,584,340 in 1909, as compared with $1,381,867 in 1899.

Horticultural crops of the state are fruits and nuts, potatoes and other vegetables, small-fruits, flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $714,269, as compared with $291,587 in 1899. In 1909 the total acreage of potatoes and other vegetables, the most important of the horticultural crops, was 114,829, as compared with 63,098 in 1899, and their value in 1909 was $6,282,904. Small-fruits increased in acreage from 1,408 in 1899 to 3,587 in 1909, when their value was $486,988. Flowers and plants and nursery products increased in acreage from 365 in 1899 to 729 in 1909, an increase of 99.7 per cent, when their value was $213,855.

The total quantity of orchard-fruits produced in 1909 was 392,607 bushels, valued at $314,027, an increase over the value and production in 1899. In 1909 the most important of the orchard-fruits were the peach and nectarine which contributed about three-fourths of the production; pears, apples, and plums and prunes producing most of the remainder. The number of peach and nectarine trees of bearing age in 1910 was 903,352; those not of bearing age, 316,132. The production in 1909 was 290,623 bushels, valued at $228,084. The pear trees of bearing age in 1910 numbered 57,630; those not of bearing age numbered 38,242. The production in 1909 was 35,554 bushels, valued at $31,069. The number of apples trees of bearing age in 1910 was 93,304; those not of bearing age numbered 96,544. The production in 1909 was 33,875 bushels, valued at $28,744. The production of plums and prunes for the same year was 31,473 bushels, valued at $24,641. Small amounts of cherries, quinces, apricots, and mulberries were also produced.

The grape-vines of bearing age in 1910 numbered 31,041; those not of bearing age numbered 20,936. The production in 1909 was 106,595 pounds, valued at $6,099, as compared with $5,927, their value in 1899.

The total production of nuts in 1909 was 796,925 pounds, valued at $73,169. The most important of the nuts are the pecans. In 1910 the pecan trees of bearing age numbered 36,527; those not of bearing age, 119,547. The production of pecans in 1909 was 723,578 pounds, valued at $70,635; that of Persian or English walnuts, 15,173 pounds, valued at $1,446; that of black walnuts, 54,624 pounds, valued at $970; and a small amount of almonds.

Tropical fruits increased in value from $8,727 in 1899 to $320,974 in 1909. The most important of the tropical fruits is the orange, of which, in 1909, there were produced 149,979 boxes, valued at $222,339. The number of orange trees of bearing age numbered 266,116 in 1910; those not of bearing age, 155,016. The fig trees of bearing age in 1910 numbered 71,464; those not of bearing age, 102,043. The production of figs in1909 was 2,025,308 pounds, valued at $87,009. Other tropical fruits produced were: 3,340 boxes of mandarins, valued at $5,945; 1,781 boxes of pomelos (grapefruit), valued at $4,069; 303 boxes of lemons, valued at $713; and 300 boxes of tangerines, valued at $500.

Of the vegetables grown in Louisiana, the sweet potato and yam are of most importance. From an acreage of 56,953, in 1909, there were produced 4,251,086 bushels, valued at $2,357,729. The production of peanuts from 25,020 acres was 412,037 bushels, valued at $422,232; the production of potatoes from 19,655 acres was 1,183,525 bushels, valued at $924,311. Other vegetables produced were: 1,962 acres of cabbage, valued at $208,678; 2,909 acres of onions, valued at $147,377; 515 acres of lettuce, valued at $94,321; 1,278 acres of watermelons, valued at $69,386; and sweet corn, 1,218 acres, valued at $62,060. Vegetables of less importance were green beans, beets, cantaloupes and muskmelons, carrots, cucumbers, okra, parsley, green peas, green peppers, radishes, spinach, tomatoes and turnips.

The acreage devoted to the production of flowers and plants increased from 89 in 1899 to 227 in 1909. The total area under glass in 1909 was 347,473 square feet, of which 260,711 were covered by greenhouses and 86,762 by sashes and frames. The value of the products in 1909 was $126,212, as compared with $76,628 in 1899.

The acreage occupied in the production of nursery products increased from 276 in 1899 to 502 in 1909, an increase of 81.9 per cent. The value of the products for the same time increased from $63,593 in 1899 to $87,643 in 1909.

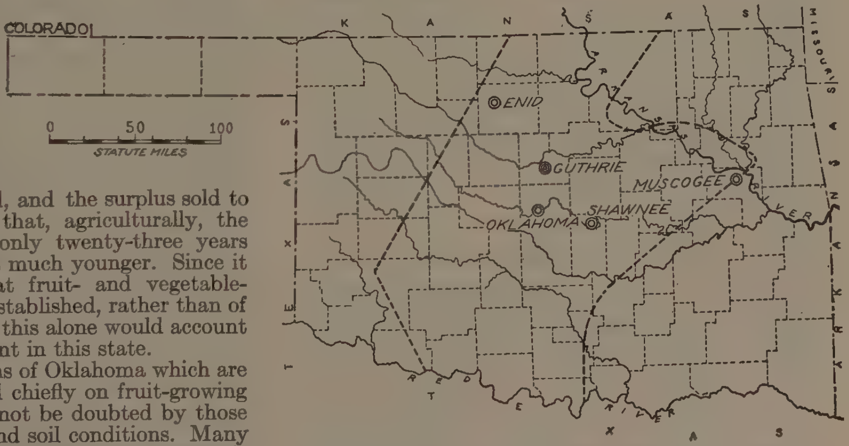
George L. Tiebout.†

Oklahoma.

At present, the horticulture of Oklahoma (Fig. 2522) is but poorly developed. The reason for the state being backward in fruit-growing and vegetable-raising is because of the short length of time since the commonwealth was first settled. The first part of Oklahoma was thrown open to settlement in 1889. Other sections adjoining were opened to entry from time to time until 1908, when the old territory of Oklahoma was combined with Indian Territory to form the present state. Even today, much of the Indian land is still held in reserve, but is gradually being allotted, and the surplus sold to white settlers. This means that, agriculturally, the oldest part of Oklahoma is only twenty-three years old, and that the remainder is much younger. Since it is a well-recognized fact that fruit- and vegetable-growing are industries of old established, rather than of young pioneer neighborhoods, this alone would account for the lack of this development in this state.

That there are many sections of Oklahoma which are destined eventually to depend chiefly on fruit-growing as a means of livelihood will not be doubted by those who investigate its climatic and soil conditions. Many neighborhoods in those parts of Arkansas, Missouri, and eastern Kansas which lie contiguous to Oklahoma are notably well adapted to fruit-growing, and there is every reason for presuming that neither soil nor climate varies materially on crossing the state line. Many of the fruit sections of Oklahoma are embraced in the old Indian Territory, and are consequently the newest part of the state.

It is manifest from the above statements that no Census reports of crops produced in this state are of any present value, except that of 1910, and that this is only of limited application.



2522. Oklahoma, showing horticultural divisions of the state.

There is little question but that Oklahoma is on the southern border of the apple-growing region. While one would not wish to say that it is impossible for market varieties to be produced which will be adapted to this southern country, they are unknown today. The pressing need of the apple-growers is for later and better-keeping varieties. Sorts like the Ben Davis, Jonathan, Missouri Pippin, and other standards of Kansas, Missouri and Illinois, ripen in late September or early October there, but in Oklahoma they are fully mature in early September. At this time the weather is still very warm and decay will frequently set in at once. This means that the Oklahoma grower must either depend on cold storage from the start or else confine himself wholly to the local market. On this account, apple-growing has hardly reached a commercial phase in any part of Oklahoma, although there is no question but that there are certain neighborhoods in the eastern part of the state which are very well adapted to the production of this fruit.

Commercial peach-growing is much more promising than the growing of any other fruit. It is difficult to say exactly where the peach districts are. In very favorable years, good crops of this fruit are secured in sections well into the western part of the state. These western neighborhoods, however, are not as certain producers of peaches as those farther east. It is probable that the eastern and southeastern part of Oklahoma comprises most if not all of the sections which are so well adapted to peach-raising that this will become the predominant industry. This is not only because this region has the characters that adapt it to the growing of peaches, but also because it has not the characters which make it good for general farming. For it has been observed everywhere that no country goes into fruit-raising so unreservedly as those which cannot make a good living any other way. Much of the land in the eastern part of Oklahoma belongs to what is known as the Ozark country. These Ozarks are a rough tableland, characterized generally by a rather thin soil. This thinness of soil, combined with the roughness, puts the grain-raiser at a disadvantage as compared with the raiser of fruit. This is the newest part of Oklahoma and much of it is still in the hands of the Indian owners, and some of the most interesting orchards belong to these people. It only needs the presence of experienced fruit-growers to change many of these neighborhoods from poor one-horse grain- and pig-farming sections to profitable fruit-raising districts. Unfortunately, during the last few years, when this country has been settling, fruit-raising has been so profitable in other states that there has been but little inducement for experienced growers to come into Oklahoma. Most of the peach-growers here at present have picked up the business, and have acquired such knowledge as may be gained by experience alone, without any training, and without learning the details of the business in some other section. This means that there is no system either to the methods of raising or of marketing peaches in this state at present. Some orchards are cultivated, but more are not cultivated. The same thing is true of all other peach-orchard operations. In marketing there is the same lack of uniformity. Peaches are shipped in all sorts of receptacles, from the four- and eight-basket crate to a bushel basket. The flaring top basket of the East is practically never seen.

Pears do not seem to be a very promising commercial proposition, except possibly in the southern and eastern counties. The reason for this is generally blight and lack of fruitfulness. There are many neighborhoods in which, in most years, pears may be raised for home use or local market with considerable success.

The status of plum- and prune-raising is practically the same as that of pears. The European or domestica plums do not seem to be well adapted to the mid-western conditions. The native varieties do well, but are not well adapted to commercial uses on account of their softness and a lack of demand on the part of the public. From the standpoint of home consumption, however, the plum is well to the front. Trees of the native varieties thrive, and in spite of the depredations of curculio and black-knot, usually bear. On account of their early fruiting, they are usually the first fruit that the new settler secures for his table. This is particularly true of the *Prunus Watsonii*, or sand-hill plum, a dwarf species inhabiting the western part of the state.

Cherries are raised only for home use, and in most years hardly enough for that. The cherry is rather exceptional in that the middle counties of the state appear to suit this tree better than those of the east. In Oklahoma, however, as in most other states, the cherry is one of the favorite yard trees, and there is probably more of this fruit raised than the Census figures would indicate.

The apricot is in much the same condition as the cherry. The central and south-central counties, although there are few or no apricot orchards, raise much of this fruit in yards and roadsides. The apricot is a much surer crop in this state than in any of the northern states, and the trees seem resistant to all the vicissitudes of our seasons.

Grapes are raised to a considerable extent for home eating, but there are practically no commercial vineyards. Although the grape is found native in nearly every part of the state, it is confined chiefly to the streams, and it by no means necessarily follows that the cultivated uplands are adapted to this fruit. That the common commercial varieties, composed, as they are, chiefly of Labrusca blood, suffer from the heat and droughts of our season, is unquestioned. In spite of this, the most commonly raised varieties belong to this Labrusca class. This is probably owing to the Oklahoma public having become accustomed to the taste of these grapes, and hence preferring them to the fruit from the stronger vines of the æstivalis and riparia class.

While the development of strawberry-growing is very small, there is every reason to believe that this will eventually become a large industry in the eastern and northeastern parts of the state. This part of the commonwealth has a climate and soil which is almost identical with the nearby strawberry regions of Missouri.

Blackberries and dewberries do very well in Oklahoma, and the only reason that there are not more commercial plantings is on account of the lack of insistent demand for the fruit. The dry winters of the prairies winter-kill the vines somewhat, but they are a comparatively sure crop, even in this part of the state.

Raspberries, currants, and, to a considerable degree, gooseberries, are apparently not adapted to the climate here. Most of the growers have abandoned these fruits, and many of them report absolute failure, after repeated efforts.

The growing of pecans is attracting very much interest in the state, chiefly on account of the immense profits reported from the South, and the fact that the trees grow wild over a large part of the state. So far as tested, the named Gulf coast sorts have proved tender to our winters, although not nearly all of these Gulf coast varieties have been tested. At present there is considerable money being made in some neighborhoods by selling the fruit from the wild trees, and some of the growers have been cutting out the trees bearing the smaller and poorer nuts and retaining those bearing the larger and thinner-shelled nuts. There is considerable overflow land in the state which seems to suit pecans particularly well, and to be adapted to but little else. It is probable that pecan-growing will occupy a prominent place in the ultimate agriculture of the state, although it will be slow in coming.

Of vegetables, there are only two grown in this state in sufficient quantities to attract the attention of the census enumerator and deserve mention here. They are the potato and the sweet potato. Although both these vegetables are raised more or less all over Oklahoma, they become commerical propositions only in the lighter soils, contiguous to the Canadian and Arkansas rivers. The growing of potatoes is chiefly the producing of early potatoes for the late June and July market. During the last few years, owing to the very high prices asked for the northern potatoes shipped into Oklahoma in the fall, the Oklahoma growers have been striving to raise late potatoes as well. In many sections, the growers raise two crops a year, digging the first crop about the first of July, when the second crop is at once planted. The yields here are not nearly so large as in the northern potato regions, but the prices are very much higher than are ever known in that section. The growing of early potatoes is an apparently stable industry, for there are few other parts of the South so favorably situated for producing early potatoes as the above-mentioned parts of Oklahoma. The growing of late potatoes, however, depends apparently on the railroads. As long as rates remain so high that fall potatoes from the North bring over $1 a bushel in this state, there will be a profit in raising them in Oklahoma. This is true in spite of the fact that analyses have shown that our southern-grown potato is not so rich in starch as those from farther north. On occasional years, early hot winds will seriously damage this crop.

There is no doubt of the adaptability of sweet potatoes to the climate of this state, and to much of the soil. Perhaps it is partly on account of the large contingent of northern farmers that the growing of sweet potatoes is not a more prominent industry than it is. The acreage of this vegetable is much less than of Irish potatoes. The sweet potato sections are practically the same as for the potato, except that the Red River Valley is also a contributing factor. The price of sweet potatoes, in the towns of Oklahoma, is usually good at all seasons. But few of the growers are familiar with any reliable methods of keeping the potatoes, so that generally the supply is confined to the fall months. Sweet potatoes are nearly, if not quite, immune to all the vicissitudes of the Oklahoma climate, but commercially they are confined to the sandy bottoms.

There are many other vegetables which grow well enough in this state to be promising commercial undertakings, but they have not yet been tested in any except the most primitive way. Some of these are muskmelons, watermelons, onions, peanuts, and possibly beans. Here, as with potatoes, the railroad factor has been an important one. This and other difficulties in marketing are preventing a greater development of these industries.

Public-service agencies for horticulture.

The Land-Grant college of Oklahoma, known as the Agricultural and Mechanical College, was established in 1890 at Stillwater, in Payne County. There are three members of the horticultural staff.

The State Experiment Station is also at Stillwater, and is run in connection with the College. There are two members on the horticultural staff. Between twelve and fifteen bulletins and circulars have been issued on horticultural subjects.

There are no schools in the state giving particular attention to horticulture. A few schools are teaching a limited amount of horticulture along with the agricultural work.

Inspection of nurseries is conducted by the State Nursery and Orchard Inspector, who is the entomologist of the Experiment Station.

Statistics (*Thirteenth Census*).

The approximate land area of Oklahoma in 1910 was 44,424,960 acres. The land in farms was 65 per cent of the land area, or 28,859,353 acres. Of this land in farms, 17,551,337 acres were designated improved land in farms; 3,568,910, woodland; and 7,739,106 as other unimproved land in farms. The number of farms in Oklahoma in 1910 numbered 190,192, 151.7 being the average acreage to a farm. [The total area is 70,057 square miles.]

The leading agricultural crops of the state are cereals, cotton, including cotton seed, hay and forage, and broom-corn. The acreage devoted to cereals increased from 4,431,819, in 1899, to 8,248,653 in 1909, when the production was valued at $71,798,662. Cotton, including cotton seed, increased from an acreage of 682,743, in 1899, to 1,976,935 in 1909, when the production was valued at $41,187,408. Hay and forage increased in acreage from 1,095,706, in 1899, to 1,347,598 in 1900, when the production was valued at $9,638,648. Broom-corn increased in acreage from 12,763, in 1899, to 216,350 in 1909, when the production was valued at $2,559,235. The value of forest products of the farms in 1909 was $1,602,720, as compared with $456,240 in 1899.

Horticultural crops grown in Oklahoma are fruits and nuts, small-fruits, potatoes and other vegetables, flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $1,127,710, as compared with $518,502, in 1899. Small-fruits increased in acreage from 1,388, in 1899, to 2,745 in 1909, when the production was 2,310,367 quarts, valued at $202,291. The total acreage of potatoes and other vegetables in 1909 was 88,362, and their value, $4,210,844. Excluding potatoes, the acreage of other vegetables increased from 33,463, in 1899, to 51,011 in 1909, when the production was valued at $2,610,239. Flowers and plants and nursery products increased in acreage from 813, in 1899, to 897 in 1909, when the production was valued at $263,968.

The total quantity of orchard-fruits produced in 1909 was 1,137,288 bushels, valued at $943,464. Apples contributed nearly two-thirds of this quantity, and peaches and nectarines most of the remainder. The apple trees of bearing age in 1910 numbered 2,955,810; those not of bearing age, 2,060,384. The production in 1909 was 742,182 bushels, valued at $573,076. The number of peach and nectarine trees of bearing age in 1910 numbered 4,783,825; those not of bearing age, 2,574,680. The production in 1909 was 357,644 bushels, valued at $326,315. The production of plums and prunes was 25,916 bushels, valued at $28,134; that of pears, 7,450 bushels, valued at $9,248; that of cherries, 2,372 bushels, valued at $4,393; that of apricots, 1,123 bushels, valued at $1,270; and that of quinces, 601 bushels, valued at $1,028.

The production of grapes in 1909 was 3,762,727 pounds, valued at $122,045. The production in 1899 was 6,344,031 pounds. The grape-vines of bearing age in 1910 numbered 2,388,213; those not of bearing age, 447,489.

The total production of nuts in 1909 was 1,019,238 pounds, valued at $62,168, as compared with 45,330 pounds produced in 1899. The production in 1909 consisted of 894,172 pounds of pecans, valued at $59,481; 94,659 pounds of black walnuts, valued at $1,591; 6,700 pounds of Persian or English walnuts, valued at $489; and 21,250 pounds of hickory-nuts, valued at $485.

Blackberries and dewberries are the most important of the small-fruits, with strawberries second in importance. The acreage of blackberries and dewberries increased from 683, in 1899, to 1,792 in 1909, when the production was 1,366,497 quarts, valued at $119,654. The acreage of strawberries increased from 626, in 1899, to 825 in 1909, when the production was 830,404 quarts, valued at $71,296. Raspberries and loganberries increased in acreage from 43 in 1899, to 85 in 1909, when the production was 74,104 quarts, valued at $6,851. Other small-fruits produced were 31,024 quarts of currants, valued at $3,559, and 8,276 quarts of gooseberries, valued at $923.

The acreage of potatoes increased from 15,360, in 1899, to 32,295 in 1909, when the production was 1,897,486 bushels, valued at $1,250,052. Sweet potatoes and yams increased in acreage from 3,576, in 1899, to 5,056 in 1909, when the production was 359,451 bushels, valued at $350,553. Other leading vegetables produced in 1909 were: 5,923 acres of watermelons, valued at $165,725; 386 acres of onions, valued at $29,143; 655 acres of cantaloupes and muskmelons, valued at $23,438; 315 acres of tomatoes, valued at $19,295; 548 acres of sweet corn, valued at $9,138; 137 acres of cabbage, valued at $9,510. Vegetables of less importance were green beans, pop-corn, green peas, and rhubarb.

The acreage devoted to the production of flowers and plants increased from 9, in 1899, to 40 in 1909. The area under glass in 1909 was 158,515 square feet, of which 148,737 were covered by greenhouses, and 9,778 were covered by sashes and frames. The value of the flowers and plants produced in 1909 was $92,016, as compared with $6,644 in 1899.

Nursery products increased in acreage from 804, in 1899, to 857 in 1909. The production in 1909 was valued at $171,952, as compared with $103,264 in 1899.

N. O. Booth.

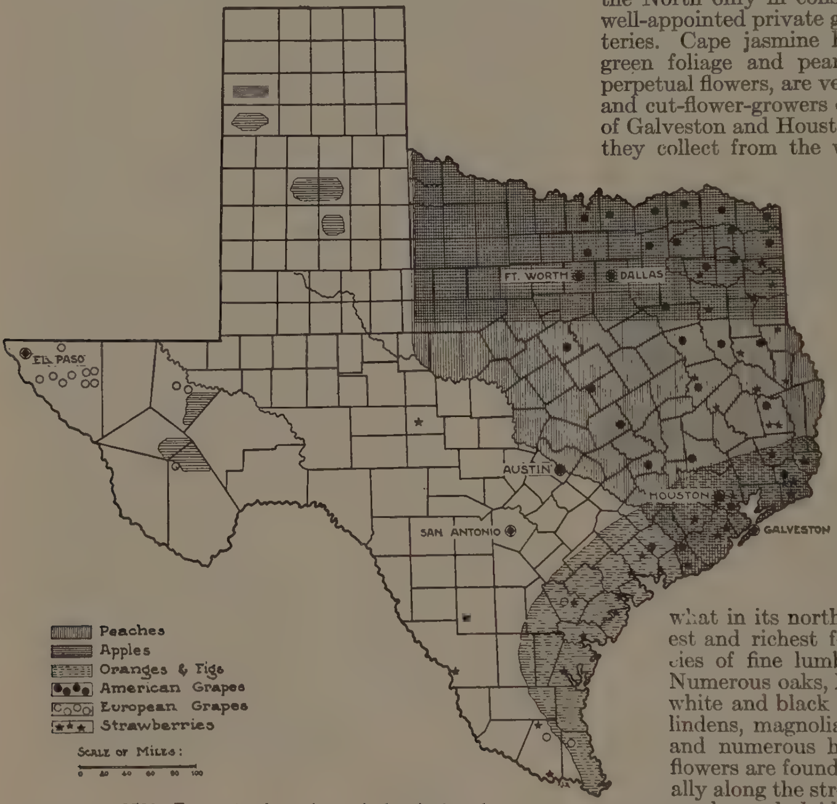
Texas.

Texas (Fig. 2523) extends in north latitude from 26° to 36½°, and in west longitude from 93½° to 106½°. Its altitude varies from sea-level, for over 400 miles along the Gulf coast, to 9,000 feet in Mt. Guadalupe, west of the Pecos River. It has a greater area of arable land in proportion to its entire area than any other state in the Union, except, perhaps, Illinois and Iowa. In 1912 it had about 4,000,000 population, but its rich soils and other natural resources can sustain, in comfort, a greater population than has Germany. There are no less than eleven rivers wending their way through the state, or by it, from northwest to southeast, the shortest of which is at least 400 miles long. It has no lakes worthy of mention, but has connected large bays, or sounds, land-locked by long islands, next the Gulf, along its entire coast, navigable for sloops and steamboats. The climate is healthful and invigorating.

The climatic belts of the state are distinctly marked and extremely different in character one from another They may be designated as follows

(1) The Gulf Coastal Plain; (2) The East Texas Forest region; (3) The Red River Valley; (4) The Black Waxy Prairies; (5) The Brown or Chocolate Plains; (6) The Staked Plains; (7) The Pecos Valley; (8) The Rio Grande Valley; (9) The Mountain region.

The Gulf Coastal Plain, extending out 50 to 75 miles from the Gulf of Mexico, varies in altitude from a few feet along the low sandy beach, to 50 and rarely 100 feet inland. Its surface in places is timbered with live-oak and pine, but mostly it is a level, black-sandy prairie. The streams are bordered in southeastern Texas with timber and undergrowth of many species, including the grand magnolia, holly, palms and many other beautiful flowering trees, shrubs, and perennial herbs. The rainfall in the southwestern extension of this belt is much less than in the eastern, where it averages about 50 inches annually, and the growth and cultural conditions vary accordingly. In trucking, celery, cabbage, strawberries, tomatoes and melons are the leading items. On the southern end of Padre Island, near Brownsville, bananas, oranges and pineapples are grown to some extent. Oranges were successfully grown and fruited along the Gulf coast for several years, but in November, 1911, a severe freeze occurred, before the wood was ripe, and killed all the trees back to the hardy trifoliata stock, where not protected by a mound of soil. Those mounded-up were uninjured below the soil, and made fine growth the summer following. This promised to be an important industry in southern Texas, but will be checked somewhat in its progress by this disaster. To permit of mounding-up safely, growers recommend budding and grafting not over 2 or 3 inches above ground, but never below, as the Satsuma would get onto its own root, and be more tender. Figs flourish everywhere in the coast country. The canned-fig industry is developing and promises to become very profitable. Dewberries grow to perfection, and wild varieties are marketed in considerable quantities. The Le Conte, Kieffer, and Garber pears do better in this region than elsewhere. Some of the Chinese Cling group of peaches, also the Honey and Peen-to types, succeed well. Japanese plums, persimmons, and various American and foreign grapes also succeed, the latter requiring to be grafted on phylloxera-resistant roots, which are found in the numerous wild vines of the state.



2523. Texas, to show the main horticultural areas.

Ornamental horticulture, in all its branches, is here characterized by a profusion and luxury of growth in foliage and flower of a semi-tropical nature. Ever-blooming roses continue to flower most of the winter. Broad-leaved evergreen trees and shrubs, known in the North only in conservatories, are here seen in all well-appointed private grounds, and in parks and cemeteries. Cape jasmine hedges, with their dark glossy green foliage and pearly white, camellia-like, sweet perpetual flowers, are very popular. Commercial plant- and cut-flower-growers do a good business in the cities of Galveston and Houston. During the winter holidays they collect from the woods great quantities of long ("Spanish") moss, holly, magnolia, mistletoe, palmetto, smilax, and the like, and ship to northern cities for decoration purposes. In May and June they send to northern florists great numbers of cape jasmine and magnolia flowers.

The great East Texas Forest region lies just north of the eastern end of the Coastal Plain, the city of Beaumont being situated in its southern extremity. Extending westward from the Sabine River on the east to the Navasota River on the west, over 150 miles, and northward to Red River about 300 miles, narrowing somewhat in its northern parts, is one of the grandest and richest forests in America. Three species of fine lumber pines are most abundant. Numerous oaks, hickories, elms, maples, beeches, white and black walnuts, gums, poplars, pecans, lindens, magnolias, holly, persimmons, sassafras, and numerous handsome shrubs and perennial flowers are found almost everywhere, but especially along the streams. The soil is generally very sandy, underlaid with red and yellow clay, and well adapted to fruits of almost all kinds. The altitude varies from 100 to 600 feet. The rainfall is ample—from 40 to 60 inches annually—and the climate is very mild. Owing to the great lumber-mill interests and lack of market facilities, nearly all horticultural pursuits have been overshadowed until recently. But at Palestine, Tyler, Troupe, Longview, Nacogdoches and some other points, large commercial peach orchards, berry plantations and canneries have been in very successful operation for a number of years and these interests are rapidly increasing. Railway facilities are growing, and altogether east Texas has a very bright horticultural future. Trucking of nearly all kinds, and fruit-growing, with berries, peaches, plums, apples (especially in northern parts), and pears, could hardly ask for better natural conditions.

The Red River Valley is a long extension to the westward—some 250 miles—of the soil, climatic and forest conditions of east Texas, excepting the pines, gums, and some other trees in its western parts. But, as the Red River runs eastward in a broad, deep, heavily timbered valley, its southern bluffs, some 5 to 10 miles wide, enjoy peculiar immunity from late frosts. Here apples flourish about as well as in northern Arkansas, and peaches have not failed entirely in fruit in almost forty years.

With the exception of a few of the tenderer shrubs, everything is grown here as well as in east Texas, and apples, grapes and some other fruits grow better and acquire higher color and flavor, owing to a less humid atmosphere. In this belt belong the cosmopolitan little cities of Texarkana, Paris, Sherman, Denison and Gainesville, in which are found many beautiful residences and grounds, many orchards, vineyards, and berry plantations. Railway facilities are excellent, and good markets lie in every direction. Trucking also is extensive. Cut-flower and general nursery business flourish in the places named.

Similar conditions prevail in some parts of the Trinity River Valley as along Red River, especially about Dallas and Fort Worth; also on the Brazos at Waco, but more of the southern type. These three cities nestle in the heart of the next great division.

The Black Waxy Prairie region of Texas lies next to east Texas on the west and to the Red River Valley on the south, extending west to about 98° and south to within 150 to 100 miles of the Gulf, a broken irregular arm of the east Texas region extending southwestwardly between it and the Coastal Plain. This region has an altitude in its southern parts of 400 to 500 feet and rises in the northwest to 1,000 feet or more. The rainfall varies from 50 inches or more in its eastern parts to 30 inches in the western parts. The foundation is white chalky lime-rock, the soil very black, sticky and exceedingly rich, highly adapted to grains, grasses and cotton, but not suitable for most fruits. The stone-fruits and blackberries do best. Onions are largely grown in Collin County of which McKinney is county-seat. Most shrubbery does well. The Bermuda-grass flourishes in Texas wherever grass can grow and is the almost exclusive lawn-grass. Very handsome yards are made by some of the farmers and many who live in the towns and cities; but most farmers in Texas have done little or nothing to beautify their homes horticulturally.

The Brown, or Chocolate Plains region of Texas, devoted principally to grazing and small grains, lies to the westward of the Black Land Region, is about 200 miles wide by 600 long, extending from Oklahoma on the north to the Rio Grande on the south, running from 1,000 feet altitude on the south and east to 3,000 feet on the west, where it ends suddenly against the cliffs of the still higher Staked Plains region.

Horticulture is in its infancy in all this vast semi-arid, high, rolling prairie country, and can do little without irrigation. Yet many wealthy stockmen there have beautiful grounds surrounding their homes, and grow their home supplies of very fine fruits. Of commerical horticulture there yet is none. The same may be said of the Staked Plains region, but its soil is dark rich loam, the country almost a dead level, except where cañons have cut into it, its altitude from 3,500 to 4,500 feet, its climate dry and very salubrious. Irrigation-horticulture in a small way is sustained from driven wells, which strike plenty of water at 10 to 30 feet. Stock-grazing is the chief commercial occupation, small grain coming next. Five or six counties northwest from Austin, in the central parts of the Chocolate Belt, are very broken, hilly and picturesque, well adapted to fruits. Nearly every home there is supplied with fruits.

The Pecos Valley lies just west of the Staked Plains, and east of a spur of the Rocky Mountains. In places it is irrigated, as at Roswell and Carlsbad, New Mexico, and Pecos City and Stockton, Texas. Commercial fruit-growing is considerable in this valley, especially at Roswell and Pecos City. At the latter place is a vineyard of 40 acres of the vinifera varieties, planted twenty years, doing finely on their own roots and very profitable, as the fruit goes to market in northern cities before any grapes are ripe in California. The Stockton region is largely irrigating and planting vinifera grape, pears, alfalfa and so on.

The Rio Grande Valley is much warmer in the same latitude than the Pecos Valley, otherwise the horticultural conditions are much the same. At El Paso and Ysleta, a little way south on the Texas side, considerable quantities of vinifera grapes of table varieties are grown under irrigation and shipped to other parts of Texas and to northern cities in August and September. Pears and plums are also grown to some extent. Farther down on the Rio Grande, at Del Rio, Eagle Pass and Laredo, grapes, figs and onions are considerably grown and shipped to the larger Texas cities and the North. The grapes are of the Old World varieties, and ripen in June; consequently they have no competition and bring fine prices. The conditions are such that immense quantities of as fine grapes of this class can be grown in this part of Texas as in the best regions of California, and the cost of getting to market is not more than half as much. Undoubtedly the triangular region between San Antonio, Laredo and Del Rio will in the near future have extensive commercial vineyards of vinifera grapes.

A vast mountainous and dry-plains region extends from the Pecos to the Rio Grande, devoted to goats, sheep and cattle; yet at Fort Davis, on a beautiful mesa, some 5,000 feet altitude, among mountains 2,000 to 4,000 feet higher, are a good many very beautiful homes, and fruits do finely, as there is sufficient rainfall and the air is very pure, so that diseases are almost unknown.

The Spanish taste in home grounds among the wealthy of southwestern Texas, who are chiefly stock-growers and merchants, is sometimes seen. It consists of a plaza, or open square in the center of the residence, having fountains (where water is to be had abundantly), and borders, beds and vases of rare tropical and subtropical flowers, shrubs and fruits. Around this highly artistic garden the house is built, often of adobe, sometimes of stone, cut and carved, in large rooms adjoining and opening into each other, all on the ground-floor and one large door opening out to the street or small front yard from a big hall, sometimes having grand arches and marble columns. No windows are in the outside walls, except perhaps in the front, the rooms all being lighted from within the plaza. Thus great seclusion is secured and a perpetual conservatory scene is had from every room. Paved walks, usually covered, run around the plaza next the rooms and similar walks cross through the plaza. This style has given way to American styles. The plaza-park prevails also in the finer hotels, as seen in some at San Antonio; and these, on an enlarged scale at various places in the denser parts of the city, give a very refreshing appearance. In the central and western parts of the state the northern and eastern style of park, cemetery and private grounds decoration is mostly copied, as is also the architecture. Some very creditable examples are seen in Dallas, Waco, Austin, Paris, Sherman, Gainesville, Fort Worth and other places.

There are numerous small, and a few fair-sized nurseries scattered over the state. Plant and cut-flower business is developing rapidly in the larger cities.

Seed business is almost entirely commercial or jobbing, few being engaged in growing seeds of any kind as a business, and the supply comes from northern and eastern growers except the grains.

The following persons, now deceased, have occupied a prominent place in the development of Texas horticulture: T. V. Munson, Denison; H. M. Stringfellow; Wm. Watson; A. M. Ramsey, Austin; C. Falkner, Waco; E. H Adams, Bonham; J. C. Newberry, Pilot Point; J. T. Whitaker, Tyler.

Public-service agencies for horticulture. (E. J. Kyle.)

The legislature of Texas, in an act approved April 17, 1871, provided for the establishment of the Agricultural and Mechanical College of Texas, which was located at College Station in Brazos county. The College was formally opened for the reception of students October 4, 1876. The Horticultural Department of the College now has four members on its instructional staff.

The Federal Experiment Station is located at College Station. The horticultural work in the Station is in charge of two men. The Station has published twenty-nine horticultural bulletins and two circulars.

Elementary courses in horticulture are taught in a number of high-schools in the state. There is a considerable amount of extension work done by members of the horticultural teaching staff and members of the extension service. Some of the societies advancing the cause of horticulture in Texas are the Texas State Horticultural Society, Texas Nut-Growers' Association and Texas Nurserymen's Association. There are also several local horticultural societies and many fruit- and truck-growers' associations for commercial purposes.

In the State Department of Agriculture at Austin, considerable time is devoted to the inspection of nurseries, and the eradication of insect pests and diseases.

Statistics (*Thirteenth Census*).

The approximate land area of Texas in 1910 was 167,934,720 acres. The land in farms was 67 per cent of this area, or 112,435,067 acres. Of this land in farms, the improved land numbered 27,360,666 acres, the woodland 27,658,413 acres, and other unimproved land in farms 57,415,988 acres. The number of all the farms in 1910 was 417,770, and the average acreage to a farm 269.1. [The total area is 265,896 square miles].

The leading agricultural crops of Texas are cotton, including cotton seed, cereals, and hay and forage. The acreage devoted to the production of cotton increased from 6,960,367 in 1899 to 9,930,179 in 1909, when the production was valued at $188,673,954, which was 63.3 per cent of the total value of all crops. Cereals decreased in acreage from 6,932,791 in 1899 to 6,716,304 in 1909, when the value of the production was $67,109,923. Hay and forage increased in acreage from 938,024 in 1899 to 1,311,967 in 1909, when the production was valued at $12,824,433. The value of the forest products of the farms in 1909 was $8,925,662, as compared with $3,520,033 in 1899.

Horticultural crops grown in Texas are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $1,824,543, as compared with $1,563,745, in 1899. Small-fruits increased in acreage from 3,904 in 1899 to 5,053 in 1909, when the production was 6,182,742 quarts, valued at $480,331. The total acreage of potatoes and other vegetables in 1909 was 202,792, and their value $12,122,255. Excluding potatoes and sweet potatoes and yams, the acreage of the other vegetables increased from 111,899 in 1899 to 124,690 in 1909, when the production was valued at $8,099,306. The acreage of flowers and plants and nursery products increased from 2,260 in 1899 to 4,182 in 1909, when the production was valued at $1,727,470.

The total production of orchard fruits in 1909 was 1,090,233 bushels, valued at $1,060,998. Peaches and nectarines contributed about two-thirds of this quantity, and apples, pears, and plums and prunes most of the remainder. The peach and nectarine trees of bearing age in 1910 were 9,737,827; those not of bearing age, 2,958,813; and the production in 1909 was 729,631 bushels, valued at $703,649. Apple trees of bearing age in 1910 numbered 1,138,852; those not of bearing age, 1,127,573, and the production in 1909 was 168,008 bushels, valued at $160,655. Pear trees of bearing age in 1910 numbered 558,478; those not of bearing age, 448,899, and the production in 1909 was 110,967 bushels, valued at $114,279. Plum and prune trees of bearing age in 1910 numbered 1,020,339; those not of bearing age, 327,765, and the production in 1909 was 75,222 bushels, valued at $77,925. Other orchard-fruits produced in 1909 were: 1,839 bushels of apricots, valued at $2,364; 1,635 bushels of mulberries, valued at $723; 1,869 bushels of quinces, valued at $740; and 1,062 bushels of cherries, valued at $663.

The production of grapes in 1909 was 1,802,618 pounds, valued at $78,325. The grape-vines of bearing age in 1910 numbered 712,201; those not of bearing age, 297,869.

The production of nuts in Texas in 1909 was 5,945,932 pounds, valued at $562,542. The pecan is by far the most important nut, the production of pecans alone being 5,832,367 pounds, valued at $556,203. The other nuts produced were: 40,658 pounds of Persian or English walnuts, valued at $3,703; 16,932 pounds of almonds, valued at $1,618; and 55,446 pounds of black walnuts, valued at $995.

Tropical fruits were produced in Texas in 1909 to the value of $122,678. Figs and oranges contributed the greater part of this quantity. Fig trees of bearing age in 1910 numbered 230,171; those not of bearing age, 585,396. The production of figs in 1909 was 2,411,876 pounds, valued at $97,078. Orange trees of bearing age, in 1910 numbered 42,384; those not of bearing age, 867,407. The production of oranges in 1909 was 10,694 boxes, valued at $22,090. Other tropical fruits produced were: 1,175 bushels of Japanese persimmons, valued at $2,136; 488 boxes of pomelos (grapefruit), valued at $866; and 224 boxes of lemons, valued at $469.

Of the small-fruits produced in Texas, strawberries are by far the most important, with blackberries and dewberries ranking next. The acreage of strawberries increased from 1,361 in 1899 to 2,161 in 1909, when the production was 4,207,056 quarts, valued at $334,651. Blackberries and dewberries increased in acreage from 2,394 in 1899 to 2,773 in 1909, when the production was 1,868,119 quarts, valued at $138,557. The other small-fruits produced in 1909 were: 97,652 quarts of raspberries and loganberries, valued at $6,302; 4,873 quarts of currants, valued at $496; and 5,042 quarts of gooseberries, valued at $325.

Of the vegetables produced, the sweet potatoes and yams, the potato, and peanut are the most important. The acreage of the sweet potato and yam decreased from 43,561 in 1899 to 42,010 in 1909, when the production was 2,730,083 bushels, valued at $2,197,799. Potatoes increased in acreage from 21,810 in 1899 to 36,092 in 1909, when the production was 2,235,983 bushels, valued at $1,825,150. Peanuts increased in acreage from 10,734 in 1899 to 64,327 in 1909, when the production was 1,074,998 bushels, valued at $1,075,110. Other vegetables of importance, that were produced in 1909, were: 5,170 acres of onions, valued at $820,972; 6,035 acres of tomatoes, valued at $597,038; 18,466 acres of watermelons, valued at $539,313; 4,462 acres of cabbage, valued at $382,349; 1,784 acres of beans, valued at $95,474; 1,685 acres of cantaloupes and muskmelons, valued at $83,363; and 1,256 acres of cucumbers, valued at $52,667. Turnips were produced to the value of $39,290; green peppers, to the value of $18,807; green peas, to the value of $17,685; sweet corn, to the value of $13,882; beets, to the value of $9,420; and asparagus amounted to $5,372 in value. Vegetables of still less importance were carrots, cauliflower, pop-corn, eggplant, lettuce, okra, pumpkins, radishes, spinach, and squash.

The acreage devoted to the production of flowers and plants increased from 167 in 1899 to 335 in 1909. The total area under glass in 1909 was 986,070 square feet, of which 907,615 were covered by greenhouses, and 78,455 by sashes and frames. The value of the flowers and plants produced in 1909 was $474,360, as compared with $120,249 in 1899.

The acreage devoted to nursery products increased from 2,093 in 1899 to 3,847 in 1909, when the value of the nursery products was $1,253,110, as compared with $314,511 in 1899.

T. V. Munson.

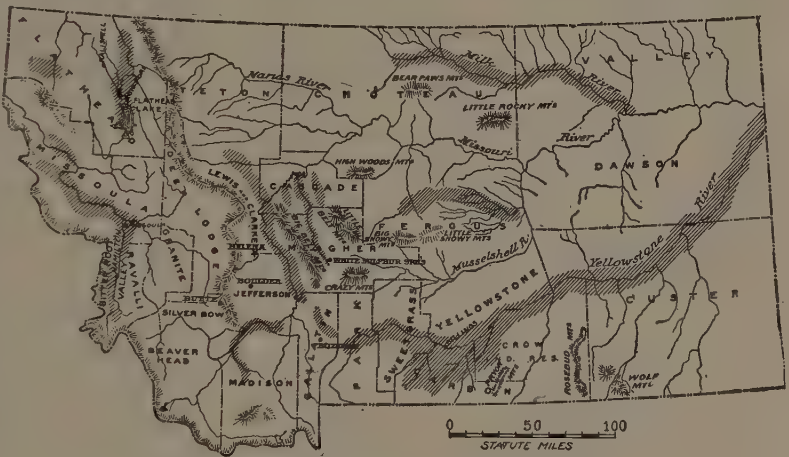
MOUNTAIN STATES.

Montana.

Montana (Fig. 2524) is the third largest state in the Union, Texas and California being first and second respectively. The eastern part of Montana is undulating plains country, with a mean average altitude of 2,800 feet above sea-level. In a mountainous state covering over 145,000 square miles, there are possibilities for great local variations, and Montana is not an exception. From east to west the average length is 535 miles, while from north to south it measures 275 miles. Of the land surface, about 30,000,000 acres are mountainous. The forest reserve embraces over 20,000,000 acres, including some which have agricultural possibilities. About 6,000,000 acres of the tillable lands are under irrigation, or are possible of irrigation, and about the same acreage is possible of cultivation under the dry-farming system.

Along the southern boundary, about 125 miles west of the state line, are the Wolf Mountains; west of these the Rosebud and Pryor mountains; toward the northern boundary and 175 miles west of the state line are the Little Rockies; west of these the Bear Paws; while dotted over the eastern and central part of the state are the Moccasins, and the Big and Little Snowies, the Belts, the Highwoods, and the Crazies. These, with the exception of the Belts, are isolated from other mountains, or detached spurs from the main range, and abound in the exceptional advantages which arise from good soil, favorable exposure, and convenient means for irrigation. About the center of the southern state line the main range of the Rockies is encountered. This range traverses the state from this point in a northwesterly direction. The summits of the main range vary from 7,500, to 10,000 feet above sea-level, and present mighty barriers to the winter storms which sweep over the country to the east and south of Montana, often bringing intensely cold weather in their wake. The climate of the state is also sensibly affected by chinooks, those much misunderstood currents of warm air which rob winter of its terrors in regions visited by them. The botanist and horticulturist have much to learn, as yet, concerning the effect of altitude upon plant growth. In a general way, it is supposed that 9,000 feet is the so-called limit of timber, although, as a matter of fact, it often happens that above this point the crowns of the mountains are composed of living rock devoid of soil and other needed adjuncts of tree growth. Illustrations of the unwillingness of plant growth to be circumscribed by altitudinal lines are found in the city of Denver, which lies 5,000 feet above sea-level. There many trees have been successfully transplanted from their natural habitat at sea-level along the shores of Puget Sound to a point nearly a mile aloft, and into a climate as naturally dissimilar as could well be found. In Cheyenne, Wyoming, there is a luxuriant development of the black locust at an elevation of 6,100 feet. This is a tree that has to be most carefully handled to avoid winter-killing in Minnesota, 5,500 feet nearer sea-level.

In the sugar-beet chart of the Department of Agriculture, a great variation of altitude will be found. It is designed to show the extent of the country in the United States adapted to beet-culture. This starts at the Atlantic coast at sea-level, extending due westward to the limit of Wisconsin. From there it jumps to Colorado, California, and also embraces the Yellowstone Valley, which is one of the most prolific sections in the beet area, considering tonnage and sugar-content. One of the largest sugar-beet factories in the United States is located at Billings, which is the largest city in the Yellowstone Valley.



2524. Montana, with regions best adapted to horticulture.

Horticulturally, Montana presents conditions for the growing of a large list of fruits, excepting the citrous and other subtropical fruits. Some scientific experiments have been conducted to determine the species adapted, and much is now being done to determine the varieties of species best suited to Montana's conditions. Observation teaches that all western sections should be carefully studied regarding the presence of alkali, as fruit-trees will not thrive in alkali soil. It is not usually a hard matter to determine such conditions, as irrigation or natural water-fall brings the salts to the surface where they rapidly crystallize. On the benches near the mountains, which are the desirable fruit-lands, alkali is seldom found.

The natural conditions for fruit-growing in Montana have been such that if trees were planted, a bountiful harvest, in due time, was assured, but with the evolutionary changes of conditions which always follow development, today the degree of success is measured by the skill and aptitude of the grower. Water for irrigation is to be found in abundance. Under irrigation, during the growing season, the moisture-content of the soil is under absolute control, which, combined with the bright sun and the clear atmosphere, makes for a strong normal growth, and by proper regulation of cultivation and irrigation, this growth is properly matured and ripened for the winter.

The lay of the valleys between the mountain ranges, and the frequency of the cañons which open out upon the benches and plains below, create air-currents which are almost a guarantee against frost-injury. These currents can be noticed long distances from the mouths of the cañons, and especially on the benches. They also prevent frosts, which gives the fruit more time for maturity than in the open country, or on level areas.

Pioneer orcharding was started with many obstacles.

Trees were freighted long distances, which made prices almost prohibitive. Seeds were brought across the plains and planted, and, when the trees were of sufficient size, cions came by mail and were grafted into them. In 1864, trees were planted in the Missouri Valley by John G. Pickering, some of which are still bearing. There are bearing orchards in Madison, Clarks Fork, Flathead, and other valleys, that were planted in the early seventies. In 1864, T. W. Harris planted the first apple tree in the Bitter Root Valley, on the bench tributary to Three Mile Creek. He brought the tree by horseback from Walla Walla, Washington. In 1870, the Bass Brothers planted the first commercial orchard in the valley near Stevensville, and in 1898 they marketed about 10,000 boxes of Transcendent crabs. The first McIntosh Reds were planted near Stevensville by Amos Buck in 1877; these trees are still strong, healthy, and productive. This variety early demonstrated its adaptability to Montana conditions, and has proved very remunerative. Early recognizing this fact, and the high quality it develops in Montana conditions, D. E. Bandman planted one of the first commercial orchards near Missoula which consisted of 1,500 McIntosh Reds, and a few other mixed sorts.

The Bitter Root Valley has a mean altitude of 3,300 feet. It is about 100 miles long, lying in the southwestern part of the state, east of the Bitter Root Range. It varies in width from 1 to 20 miles, and is traversed its entire length by the Bitter Root River which empties into the Missoula River near Missoula. The bitter-root flower is very abundant in the Bitter Root Valley and the Missoula Valley. This valley has seen the greatest horticultural development of any section in the state, the Flathead Valley ranking next in order of development; after which come the Missoula Valley, the Plains Valley, the Yellowstone, including its tributary Clarks Fork, Jefferson and South Boulder. The Bitter Root Valley represents as many orchard acres as do the other sections combined. It has a soil especially adapted to apples, cherries, pears, plums, and small-fruits, while in some favored locations grapes and peaches thrive. Sweet cherries, particularly the varieties Bing, Lambert, and Royal Ann, develop a high degree of perfection. The soil is a decomposed granite with a liberal amount of loam, and almost a total absence of alkali. To one unfamiliar with the formation it seems a gravelly, stony, almost worthless combination, but when the cultivator is put into action, water and systematic operations applied, its productive powers are wonderful. The benches, which are the desirable fruit areas, are so fertile that there is a tendency for an overgrowth of tree, and abnormal fruitage. The soil has a liberal mixture of clay, but not sufficient to cause it to bake after irrigation. The orchardists of the Bitter Root Valley have learned that excessive watering has injured more trees than has any other operation. The theory advanced that fruit grown under irrigation is inferior to that grown with a natural rainfall has long since been exploded. The necessary amount of moisture, which can be absolutely controlled under irrigation, coupled with the clear atmosphere, and bright sun, develops a color, and with that goes quality unexcelled. Such conditions can only be found in similar altitudes under irrigation, or systematic frequent, cultural methods. The orchards in the Bitter Root Valley range in size from the home orchard, consisting of about 100 trees including many varieties, to commercial orchards of 100 to 2,000 acres each containing only a few varieties. Many of the large tracts are subdivided. During the past five years, the orchard development has been very rapid, there being an average of 1,000,000 trees planted annually. Varieties in the orchards planted by the pioneers were principally the hardy sorts, as hardiness was considered to be the necessary element of the tree. This filled the valley with apples of an inferior quality, but later developments demonstrated the fact that the conditions were favorable for the growing of higher grade fruit, hence the young orchards are planted with up-to-date, standard varieties.

Some varieties of grapes are proving very satisfactory in the state, and the time is near at hand when Montana grapes will occupy a prominent place in her list of fruits.

Although there is none of the nut-bearing trees indigenous to Montana, yet black walnut, butternuts, English walnuts, chestnuts, filberts and hickories thrive when planted in the state, and where sufficiently old they are producing annual crops of nuts.

Small-fruits are grown in all parts of the state with unparalleled success. Every ranch home in the state can be supplied with small-fruits from the home patch, if the proper varieties are selected and given good care.

Great success has been achieved in the growing of vegetables wherever it has been tried. In all of the newly settled parts of the state, as well as in the older developed valleys, wherever locations are carefully selected for the orchard and garden, fruits and vegetables can be grown to supply the home needs, and in the valleys especially adapted in the different parts of the state, commercial enterprises are profitable.

The growing of the smaller vegetables, such as peas, beans, and the like, is being stimulated by the establishment of canning factories. A very large one, located at Bass Spur in the Bitter Root Valley, is handling peas, beans, pumpkins, squash, tomatoes, and all of the different fruits. The cantaloupe and watermelon industry is becoming a prominent factor in the Yellowstone Valley near Billings. Cucumber-growing for pickles is a leading branch of the vegetable-growing in the Yellowstone Valley. A pickle factory at Billings consumes the product from a large acreage.

The growing of vegetable seed is becoming one of the leading industries in some parts of the state. Seed pea-growing has been especially remunerative in valleys where tried. The growing of alfalfa seed is a leading enterprise in many of the dry-land sections in the eastern part of the state. Montana alfalfa seed always stands foremost in the markets.

A rapidly growing demand for the winter flowers to supply the Pacific coast trade has induced the leading florists in the important cities to increase their output until it has become one of the leading branches of the florists' trade. New plants have been built for this purpose and many of the older ones have been enlarged.

There is a great increase in the demand for ornamentals in the cities and towns, and also in the country districts. Some of the nurserymen are catering to this branch of trade almost exclusively, only growing fruit-trees sufficient to supply local demands.

Bees and honey are profitable side issues with many farmers and fruit-growers. Good honey always finds a ready market and the quality of Montana honey is unsurpassed. In the extensive alfalfa and orchard sections, bees find extensive range for ideal feeding-grounds. Good prices are always paid for Montana comb or strained honey.

Among those influential in developing Montana horticulture may be mentioned Daniel Bandmann of Missoula, one of the early planters of McIntosh Red apples, and M. H. Pierce of Plains, one of the pioneer planters of the commercial orchard in Montana.

Public-service agencies for horticulture.

The Land-Grant college of Montana is located at Bozeman, and was established in 1893. There are two members of the horticultural staff.

The Experiment Station is located at Bozeman and there is also a sub-station at Victor in the Bitter Root Valley. About thirty horticultural bulletins have been issued.

The Extension Department of the College holds schools in different sections of the state. There is no horticulture taught in the public schools.

The inspection services come under the direction of the State Board of Horticulture, through the State Horticulturist. The fruit sections are divided into districts and an inspector is provided for each district.

Statistics (*Thirteenth Census*).

The approximate land area of Montana in 1910 was 93,568,640 acres, including 115,840 acres in Yellowstone National Park. The land in farms was 13,545,603 acres, or 14.5 per cent of the land area. Of these 13,545,603 acres in farms, 3,640,309 were improved; 595,870 were woodland; and 9,309,424 were other unimproved land in farms. The total number of farms in 1910 was 26,214. The average acreage to a farm was 516.7. [The total area is 146,997 square miles.]

The leading agricultural crops are hay and forage, and cereals. The acreage devoted to hay and forage increased from 875,712 in 1899 to 1,135,376 in 1909, when the value of the production was $12,344,606, which was 41.5 per cent of the total value of all crops. The acreage of cereals increased from 254,231 in 1899 to 635,807 in 1909, when the value of the cereals produced was $12,251,345, or 41.2 per cent of the total value of crops produced. Sugar crops increased in acreage from 2 in 1899 to 8,821 in 1909, when the value of the products was $547,178. The value of forest products in farms in 1909 was $541,800, as compared with $176,134 in 1899.

Horticultural crops produced are fruits, small-fruits, vegetables including potatoes, and flowers and plants and nursery products. The value of fruits produced in 1909 was $609,095, as compared with $59,587 in 1899. Small-fruits increased in acreage from 554 in 1899 to 562 in 1909, when the production was 766,791 quarts, valued at $86,586. In 1909 the total acreage of potatoes and other vegetables was 28,010, and their value $2,227,736. Excluding potatoes, the acreage of vegetables increased from 4,272 in 1899 to 7,300 in 1909, when the value of the production was $928,906. Flowers and plants and nursery products increased from 79 acres in 1899 to 361 acres in 1909, when the value of their products was $279,028.

The total quantity of orchard-fruits produced in 1909 was 591,088 bushels, valued at $609,078. Apples contributed more than 95 per cent of this quantity, the production being 567,054 bushels, valued at $566,938. The number of apple trees of bearing age in 1910 was 696,753; those not of bearing age, 1,308,066. The cherry trees of bearing age in 1910 numbered 19,938; those not of bearing age, 24,237. The production in 1909 was 7,497 bushels, valued at $17,985. The pear trees of bearing age in 1910 numbered 10,297; those not of bearing age, 12,806. The production was 7,543 bushels, valued at $12,008. Plums and prunes of bearing age in 1910 numbered 21,140; those not of bearing age 15,001; and the production in 1909 was 8,777 bushels, valued at $11,642. Peach and nectarine trees of bearing age in 1910 numbered 538; those not of bearing age, 3,386; and the production in 1909 was 128 bushels, valued at $235. Apricots were also produced in 1909 to the value of $269.

Grapes are of comparatively no importance, as are also nuts, there being a production of grapes valued at only $17, while no value was placed upon the small quantity of nuts produced.

Strawberries are by far the most important of the small-fruits, with raspberries and loganberries second in importance and currants, third. The acreage devoted to the strawberry decreased from 281 in 1899 to 265 in 1909, when the production was 406,038 quarts, valued at $46,870. The acreage of raspberries and loganberries increased from 80 in 1899 to 113 in 1909, when the production was 165,473 quarts, valued at $19,732. Currants decreased in acreage from 120 in 1899 to 115 in 1909, when the production was 123,031 quarts, valued at $12,195. There were also produced 36,321 quarts of blackberries and dewberries, valued at $4,020 and 35,896 quarts of gooseberries, valued at $3,765.

The acreage devoted to potatoes increased from 9,613 in 1899 to 20,710 in 1909, when the production was 3,240,696 bushels, valued at $1,298,830. The more important of the other vegetables produced in 1909 were: 359 acres of cabbage, valued at $56,210; 119 acres of onions, valued at $15,310; 164 acres of sweet corn, valued at $13,692; 11 acres of celery, valued at $4,800; 34 acres of rutabagas, valued at $3,960; and 69 acres of turnips, valued at $3,858. Vegetables of less importance produced in 1909 were green beans, beets, cantaloupes and muskmelons, carrots, cauliflower, horseradish, tomatoes, and watermelons.

The acreage devoted to the production of flowers and plants increased from 17 in 1899 to 20 in 1909. The total area under glass was 308,939 square feet, of which 289,024 were covered by greenhouses and 19,915 by sashes and frames. The value of the flowers and plants produced in 1909 was $104,601, as compared with $33,630 in 1899.

The acreage devoted to nursery products increased from 62 in 1899 to 341 in 1909. The value of the nursery products in 1909 was $174,427 as compared with $17,825 in 1899.

M. L. Dean.

Idaho.

The state of Idaho (Fig. 2525), lying west of the Rocky Mountains, is of vast extent and wide diversity of topography. It has a range north and south of approximately 485 miles, extending from the 42nd to the 49th parallels of latitude. Its breadth east and west, at its widest point, is about 310 miles. Taking the state as a whole, the altitude ranges from that of central and northern Indiana to more than 5,000 feet above the highest peaks of the Appalachian system.

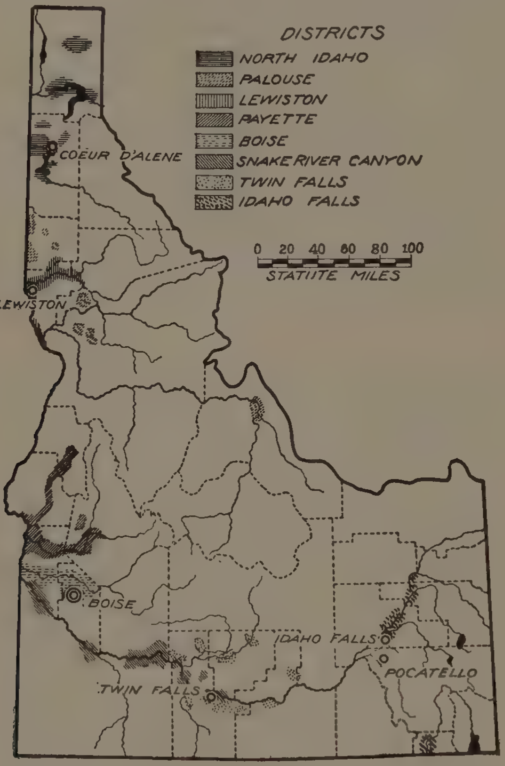
Some of the salient features of Idaho are its sage-brush plains, high snow-capped mountains and timbered plateaus. Along the eastern border of the state lie the Cœur d' Alene, Bitter Root, Cabinet and many other ranges of mountains. The Owyhee Mountains lie in the southwest corner and their lateral spurs extend almost to the Snake River. The native vegetation of the whole of the southern part of the state, as far north as the middle of Washington County, is sage-brush. This entire area is a vast agricultural region, having at the present time 1,843,039 acres of irrigated lands. South Idaho is an arid region, the rainfall for that part of the state being from 8 to 15 inches. The timbered plateau extends over most of the northern and central parts of the state. The principal trees found in this area are yellow pine, red fir, and white pine. The northern part of the state is humid, the annual precipitation varying from 20 to 25 inches. The agricultural lands lie mostly near the western border. The state is entirely drained by the Snake River and other tributaries of the Columbia.

The development of the fruit industry in Idaho is interesting. In the year 1836, H. H. Spaulding started an orchard on the Clearwater River, a few miles above Lewiston, at a place now known as Joseph. Later plantings were made in the southern part of the state in the year 1862. Two small orchards were set out on the Snake River near the Brown Lee country. Small plantings were also made on the Payette River in 1863 and near Boise in 1865. From these small plantings, the fruit industry has developed until now there are over 120,000 acres planted to orchards.

Owing to differences in altitude and climatic conditions, the state may be divided horticulturally into several distinct districts.

The North Idaho or Panhandle district includes the timbered territory of northern Idaho and especially the country around Cœur d'Alene, Hayden Lake, Pend Oreille Lake, Sandpoint, Bonners Ferry, Clarks Fork, Rathdrum, and Post Falls. It includes all of Bonner County and parts of Kootenai, Shoshone, Latah, Clearwater and Idaho counties. It is a large district and there is considerable variation in the conditions in different parts of it.

The soils of the northern part of the state vary in texture from silt loams to sandy loams and in color from red to black. The climate is mild in summer and not severe in winter. The elevation varies from 1,500 to 2,500 feet. The annual precipitation is from 20 to 25 inches and is sufficient to mature horticultural crops although irrigation is practised in several localities.



2525. Idaho, with most important horticultural parts.

While a large number of varieties of apples are grown in this district, the Wagener is apparently the leader. Northern Idaho is, however, much more of a natural pear than apple district. The growers have less trouble with blight than in some other sections of the state. This is not a peach nor a grape district and practically none of these fruits is grown. In favored localities, a few early peaches, such as Hale Early, and early grapes such as Moore Early, might be grown. All sour cherries do well, and in parts of the district excellent sweet cherries are raised. All the other small- and tree-fruits are grown successfully. Some growers report that loganberries cannot be raised, while others state that they do very well.

The local conditions, such as soil, air-drainage, elevation and slope are important considerations in the establishment of an orchard in this district.

The Palouse district includes all of the typical rolling wheat-growing region, known as the "Palouse country." The commercial orchards are mostly located around the towns of Viola, Moscow, Potlatch, Genesee and Princeton. As conditions are very similar on the "Camas prairie" which lies in Idaho, Lewis, Clearwater, and Nez Perce counties, it is also included in the Palouse district. The larger plantings of fruit on "Camas prairie" are found in the vicinity of the towns of Grangeville, Cottonwood, and Nez Perce.

Irrigation is not necessary in this district, the rainfall being from 20 to 25 inches, which is sufficient to grow crops successfully, although a good dust-mulch is essential in order to obtain size of fruit. The deep, friable soils are of basalitic formation, very fine in texture, and hold moisture remarkably well. The elevation varies from 2,000 to 3,500 feet.

The proper choice of a site is very essential to successful orcharding. The orchard should be located on a slope and the lower side should be at a somewhat greater elevation than the bottom of the valley. This insures air- as well as good soil-drainage. As cold air settles to the lower levels, low places are subject to frost and for that reason low-lying basins or pockets should be avoided for orchard purposes.

Experiments have shown that greater color may be secured on apples in this district by summer pruning.

Pear-growing is rapidly gaining prominence in certain parts of the Palouse district. All sweet cherries do exceptionally well. The Bing is the leader, although the Royal Ann and Lambert are excellent. The sour cherries also find here soil and climate congenial to their growth. The Italian prune does not attain the size which it reaches in some of the the irrigated sections of the state, but the quality is excellent. Peaches are nearly always killed by frost and practically none is raised in the district; the same is true of grapes.

The strawberry is one of the most popular fruits grown. It thrives well in practically all parts of the district. The Clarks Seedling is a favorite on account of its superior shipping qualities, its flavor and its yield. Very few loganberries are raised although they apparently do very well. All other small-fruits grow well when cared for in a proper manner.

The Lewiston district includes the territory around the town of Lewiston in the Lewiston Valley. It extends up the Clearwater Valley to Stites; up the Potlatch Creek Valley to Kendrick; and south from Lewiston along the Snake River. The average elevation is low. It varies from 700 feet to about 2,000 feet at the upper end of the Potlatch Creek Valley. The annual precipitation ranges from 12 to 20 inches. Irrigation is practised in the Lewiston orchards as well as in parts of the Clearwater and Snake River valleys. Practically all kinds of fruits of excellent quality are raised here. In a few favored localities, European grapes, such as Flame Tokay, Muscat, and the like are grown successfully. A large percentage of the fruit in this district is grown on a bench about 3 miles southeast of Lewiston at an approximate elevation of 1,500 feet, known as the "Lewiston orchards." In these tracts there are about 6,000 acres. A few varieties of fruit are grown in this locality that do not do well in other parts of the state, among them being the Spitzenberg and Yellow Newton varieties of apples.

The Payette district includes the territory along the Payette River from its mouth to the Horseshoe Bend and Brown Lee country; along the Snake River from Weiser to Payette; and along the Weiser River from Weiser to the Council Valley. A large percentage of the fruit is planted around the towns of Payette, Fruitland, New Plymouth, Emmett, Woods Spur, Jonathan and Weiser. This is the largest fruit district of Idaho, calculated on the basis of the acreage planted to fruit. The soils are volcanic ash and vary in texture from light sandy loams on the uplands to heavy dark loams in the valleys. The annual precipitation ranges from 10 to 15 inches. Irrigation is necessary.

The Council Valley section is located along the upper Weiser and Council rivers. Its elevation varies from

3,000 to 4,000 feet. The protection is very good and fruit of fine quality is grown. Approximately 3,000 acres are in fruit at the present time.

Almost all kinds of fruit of excellent quality are grown in the Payette district. However, at the present time, apples and prunes are the leaders in importance from a commercial standpoint. Blackcap raspberries are also of some importance commercially. Almost all kinds of apples grow well. The Arkansas Black is one of the best money-makers, with the Rome Beauty a close second. The acreage in Jonathans is large.

Pears are not grown extensively at the present time in the Payette Valley. Very fine peaches are grown, also all kinds of cherries, Italian prunes, plums and practically all of the small-fruits and American grapes.

The "Emmett bench," being farther up the Payette River valley, presents conditions slightly different. The protection is better and there is a longer growing season. In this section, all American varieties of grapes mature well and are of excellent quality. In favored situations, the European varieties, especially the Malaga, Sweetwater, Cornichon, Muscat and Thompson Seedless, are grown. The Tokay is also grown, although it does not always mature properly.

The Boise Valley district includes the entire Boise Valley with Boise at one end and Parma at the other. It is about 35 miles long and varies in width from 2 to 10 miles. While fruit is raised in the entire valley, most of the commercial orchards are found in the country around the towns of Boise, Eagle and Star, Parma, Collister and Middleton on the north side of the River, and Meridian, Nampa, Caldwell and Roswell on the south side. There are approximately 25,000 acres and it is the second largest fruit district in Idaho. While many varieties of apples do excellently in this district, the Rome, according to many of the growers, is the most profitable. However, the growers are almost unanimous in agreeing that the Italian prune is the leading money-maker in the Boise Valley at the present time. The sloping ground nearer the mountain ranges is best adapted to the growing of peaches, sweet cherries and grapes commercially. In the lower elevations, there is great danger of frost. Sour cherries succeed well in the level, open country. Berries of all kinds succeed well and there is seldom a failure, although strawberries are sometimes affected by a late spring frost. The soils of the Boise Valley are very rich. The elevation varies from 2,000 to 3,000 feet. The annual precipitation is from 10 to 15 inches. Irrigation is depended upon to mature crops grown in the valley.

The Snake River Cañon district consists of: (*a*) The Homedale section, which includes Indian Cove, Central Cove, Sunnyside, Fargo and Peaceful valleys. All of these are coves along the Snake River. This section is well adapted to fruit as the climate is excellent for fruit-growing purposes. However, trees should not be planted on the adobe land on the floor of the river valley. There are about 2,000 acres in this section, which are distributed along the Snake River for 30 miles. (*b*) The Upper Snake River Cañon section which consists of Grand View, Medbury Valley, Glenns Ferry, King Hill, Swiss Valley, Hagerman Valley, Crystal Springs, Niagara Springs and Blue Lakes. This is approximately 100 miles long and is a narrow cañon varying in width from 1 to 4 miles. The fruit is planted in spots.

The entire district is located directly along the Snake River. The hills or cañon walls on each side of the river afford an excellent protection, although there is a wide variation. At Blue Lakes, the cañon walls of the river are very steep and about 800 feet high, while in the Homedale section, the valley is much wider and the hills not nearly so abrupt nor high. This entire area has a mild climate and long growing season, well adapted to the growing of fruits, and there are localities where even tender fruits, such as European grapes, are grown successfully. Apples thrive well and are grown commercially. Peaches, sweet cherries, grapes, and the like, have the advantage of a good local market, due largely to the fact that they ripen earlier than those grown outside of the cañon district. Sour cherries are excellent and sweet varieties succeed well. Prunes, plums, strawberries and all of the small-fruits grow well and produce abundantly.

The Twin Falls district includes: (*a*) The territory known as the North Side Twin Falls section and the surrounding country where the conditions are similar, especially the vicinity around the towns of Ticeska, Bliss, Jerome, Gooding, Wendell, Shoshone and Richfield. In this entire section, there are approximately 6,000 acres in fruit. (*b*) The South Side Twin Falls section, especially the area surrounding the towns of Hansen, Kimberly, Twin Falls, Filer, Buhl, Minidoka, and Burley. Minidoka and Burley are located on the Minidoka project and at the present time very little fruit is grown in this vicinity. In this section there are about 19,000 acres in fruit. (*c*) The Salmon Tract is a flat, irrigated country located to the east of Salmon River and watered by the Salmon River and Deep Creek. There are approximately 3,000 acres in fruit.

The average elevation of this district is rather high, varying from 3,500 to 4,500 feet. The soil is a clay loam and is excellent for the production of fruit. Throughout the entire district, irrigation must be practised in order to produce crops. Peaches and American grapes are grown to a limited extent, although these are much later than those grown in the cañon district nearby. Few sweet cherries are grown. Apples are the leading commercial fruit, although sour cherries, prunes, plums and all the small-fruits will grow to perfection. Occasionally a late frost affects the berries. This district is still very young from a horticultural standpoint as most of the land was first irrigated about ten years ago.

The Blackfoot and Idaho Falls district consists of a strip of land running from Blackfoot through Idaho Falls and on to St. Anthony, being approximately 80 miles long and 30 miles wide. The average elevation is about 4,700 feet. There is a gradual rise in elevation from Blackfoot to St. Anthony of about 13 feet to the mile. In general, the soil is excellent The area planted to fruit in this district is small compared with some of the other fruit districts of Idaho. There are some favored localities where commercial plantings have been made. Sour cherries, dewberries, blackberries and blackcap raspberries are grown on a small scale. Prunes and plums succeed well while strawberries, red raspberries, gooseberries and currants grow to perfection.

Public-service agencies for horticulture.

The University of Idaho was established in 1889, by an act of the Territorial Legislature, at Moscow. The College of Agriculture was established in 1891, by order of the Board of Regents, as one of the colleges of the University. The horticultural staff consists of four members.

The Experiment Station is a regularly constituted department of the University, and was also established in 1891. The gardens and orchards, consisting of 45 acres, give ample room for all research work, which is being carried on at the present time. Since the establishment of the Experiment Station, twenty-seven bulletins and circulars have been published, having a direct bearing upon horticultural subjects.

The Extension Department of the University was established in 1912, with headquarters at Boise.

The Horticultural laws of the state of Idaho provide for a State Horticultural Inspector, whose jurisdiction shall extend throughout the state. To render more efficient service, the state has been divided into fourteen districts, a deputy horticultural inspector being placed in charge of each district.

Statistics (*Thirteenth Census*).

The approximate land area of Idaho is 53,346,560 acres, which includes 32,640 acres in Yellowstone National Park. Of the total land area, 5,283,604 acres or 9.9 per cent is in farms, of which 52.6 per cent or 2,778,740 acres are improved; 584,556 acres are in woodland; and 1,920,308 acres are classified as other unimproved land in farms. There are in the state 30,807 farms, the average acreage of which is 171.5 acres. [The total area is 83,888 square miles.]

The leading agricultural crops are cereals, hay and forage, sugar crops, and forest products of the farm. The cereals in 1909 occupied 847,138 acres as compared with 369,788 acres in 1899. This showed an increase in acreage of 129.1 per cent for the period. The value of the cereals in 1909 was $16,026,676 or 46.4 per cent of the total value of all crops. Hay and forage increased in acreage 42.7 per cent for the same period, the acreage being 513,656 in 1899 and 732,886 in 1909. The value of the hay and forage for 1909 was $12,099,963, or 35.2 per cent of the total value of all crops. The percentage of improved land occupied by the cereals and hay and forage was 30.5 and 26.4, respectively, in 1909. Sugar crops, in 1909, occupied 15,630 acres as compared with 21 acres in 1899 and the value of the sugar products in 1909 was $815,068. The value of the forest products of the farms in 1909 was $1,280,512, as compared with $315,821 in 1899.

Horticultural crops grown are fruits and nuts, vegetables including potatoes, small-fruits, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $882,526, as compared with $371,273 in 1899. Small-fruits increased in acreage from 957 in 1899 to 1,673 in 1909, when the value of their products was $201,525. Vegetables lead in value of the horticultural crops grown in Idaho. In 1909 the total acreage of potatoes and all other vegetables was 38,371 and their value $2,591,199. Flowers and plants and nursery products increased in acreage from 120 in 1899 to 548 in 1909, when their value was $186,548.

The total quantity of orchard-fruits produced in 1909 was 924,223 bushels, valued at $863,516. Apples contributed more than two-thirds of this quantity; plums and prunes most of the remainder. In 1910, there were in Idaho 1,005,668 apple trees of bearing age and 1,539,896 apple trees not of bearing age. The production in 1909 was 659,959 bushels, valued at $610,504. Plum and prune trees of bearing age in 1910 numbered 302,855; those not of bearing age, 98,017. The production in 1909 was 179,027 bushels, valued at $132,804. Peaches and nectarines are of interest for while the number of trees of bearing age numbered only 73,080 in 1910, those not of bearing age numbered 212,995. The production in 1909 was 18,734 bushels, valued at $28,149. In 1909 the production of pears was 42,649 bushels, valued at $48,045; that of cherries 22,609 bushels, valued at $41,766; and that of apricots 1,108 bushels, valued at $2,034. The production of quinces and mulberries was of little importance.

The grape-vines of bearing age in 1910 numbered 68,269; those not of bearing age, 124,806. The production in 1909 was 604,227 pounds, valued at $18,814.

Nuts are of little or no importance in Idaho. The nut trees of all varieties in 1910 of bearing age numbered only 1,379 and those not of bearing age, 3,495. The production in 1909 was 3,328 pounds, valued at $196.

Strawberries are by far the most important of the small-fruits raised in Idaho, with raspberries and loganberries ranking next. The acreage of strawberries increased from 239 in 1899 to 698 in 1909, when the production was 953,723 quarts, valued at $92,904; the acreage of raspberries and loganberries was 496 in 1909 and the production was 575,209 quarts, valued at $59,854. Other small-fruits produced were: 249,984 quarts of blackberries and dewberries, valued at $24,688; 161,230 quarts of currants, valued at $13,760, and 130,987 quarts of gooseberries, valued at $10,317.

Of the vegetables, the potato was by far the most important. The acreage increased from 9,313 in 1899 to 28,341 in 1909, an increase of 204.3 per cent. The value of the 4,710,262 bushels produced in 1909 was $1,583,447. The most important of the other vegetables grown in 1909 were: 289 acres of cabbage, valued at $43,517; 213 acres of cantaloupes and muskmelons, valued at $15,407; 165 acres of watermelons, valued at $15,016; 85 acres of onions, valued at $17,065; and 42 acres of tomatoes, valued $8,840. In 1912, beans were valued at $210,000 and peas at $725,000. There were also grown in smaller quantities, carrots, celery, sweet corn, cucumbers, and turnips.

The acreage devoted to flowers and plants increased from 5 in 1899 to 18 in 1909. The area covered by glass was 59,477 square feet, of which 58,727 were covered by greenhouses and 750 by sashes and frames. The value of the flowers and plants produced in 1909 was $43,314, as compared with $2,805 in 1899.

The growing of nursery products was of more importance than the growing of flowers and plants. The acreage occupied by nursery establishments increased from 115 in 1899 to 530 in 1909, an increase of 360.9 per cent. The value of the nursery products in 1909 was $143,234, as compared with $38,431, the value in 1899.

C. C. Vincent.

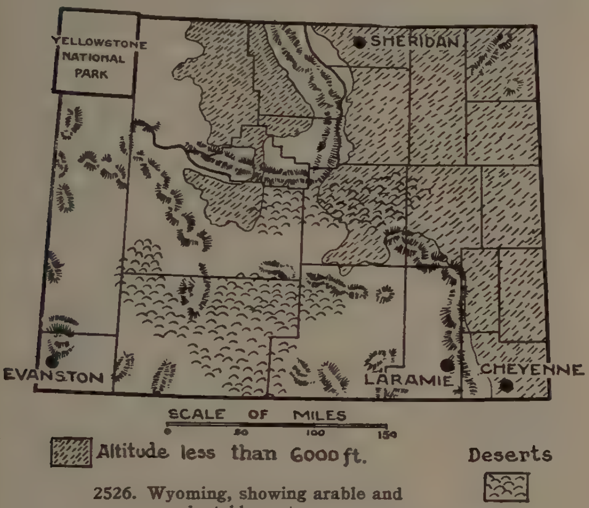
Wyoming.

The agricultural land in Wyoming (Fig. 2526) is at a higher average altitude than that in any other state. Broadly speaking, the range is from about 3,500 feet to twice that height. In a few protected valleys a limited agriculture is practised at even greater elevations, but most of the recognized districts lie below 6,000 feet. Taking the state as a whole, more than one-half the total area is above 6,000 feet. This includes the high mountain ranges which, as a rule, are forest-covered and included in the National Reservations. The conservation policy has nowhere been better exemplified than in Wyoming, where its beneficent results are seen not only in the husbanding of the timber resources, but also and more particularly in the equalized water-flow in the streams, and the larger, safer and more equitable use of the forests as grazing-lands. Perennial streams flow in every direction from the mountains and furnish enough water for the irrigation of very extensive tracts. In the course of time, when provision shall have been made for the impounding of all of the flood-waters, the areas thus reclaimed will be much greater than at present. It has been estimated that there is a sufficient water-supply to reclaim about 12,000,000 acres, only about one-fourth of which is now under canals.

Wyoming extends some 355 miles from east to west, and 276 from north to south, embracing something more than 97,000 square miles. It lies in the very heart of the Rocky Mountains, three great river systems, the Missouri, the Columbia, and the Colorado arising within its boundaries. As would be expected, there is great diversity of climate, soil and vegetation (indigenous and introduced). There are protected valleys, bench-lands, and fertile foothills; semi-arid plains, bleak plateaus, and saline deserts; forested slopes and snow-capped mountains. These are further diversified by marshlands in the valleys and occasional alkali ponds on the plains, and splendid fresh-water lakes in the mountains, thus preventing even a semblance of monotony in the geographical configuration. A physical environment so complicated readily accounts for the fact that Wyoming's native flora is far richer in the number of species than any of the other states, except possibly two or three of the other and larger mountainous ones, notably California and Colorado. The mean annual temperature varies from less than 40°F. to about 50°.

The rainfall is as little as 4 to 6 inches per annum in the Red Desert and reaches a maximum of 30 inches or more on the higher mountains. The average for the irrigated agricultural districts is probably less than 12 inches, while in certain localities where "dry-farm" methods are proving successful it may be as much as a third more. In the eastern part of the state, particularly in Crook, Weston, Niobrara, Goshen, and Laramie counties, many new communities have been established in the last decade where general farming is practised, the natural rainfall being sufficient in average years to grow profitable crops if the water be wisely conserved by the new approved methods of tillage.

The last decade has seen also the breaking up of many of the great stock ranches and ranges into smaller holdings. The marked increase in the state's population is due primarily to the settlement of some of the agricultural lands by farmers from the older commonwealths. Wyoming has therefore entered upon a new era,—a time when it will be seen that a diversified agriculture is the basis of an enduring prosperity. The natural conditions make the live-stock business of paramount importance. The soil is cultivated principally, in most parts of the state, to increase the amount of stock-food, and little intensive farming has been inaugurated. Some of the ranches that extend for miles along the streams have not yet known the use of a plow except in the construction of the ditches to irrigate the native meadows. This condition of things is, however, rapidly passing. The large holdings are being broken up into irrigated farms, thus supporting scores of families instead of a few non-resident owners of the incorporated live-stock companies. Progress in the direction of home-building has also been promoted by the great government projects in conservation and irrigation, as for example the Pathfinder and the Shoshone dams, the canals from which are reclaiming hundreds of thousands of acres. The coming in of the sugar-beet industry, with its factories, is further adding to the population.



2526. Wyoming, showing arable and adaptable parts.

The state as a whole will not reach great commercial importance because of its horticultural products, but certain rather extensive districts, primarily parts of Big Horn, Fremont, Natrona, Goshen, Sheridan, and Washakie counties, have lands that will be worth more as apple and plum lands than for any other purpose. Some of the hardy fruits have been grown in every county in the state and in most of them there are many locations in which astonishingly satisfactory results have been attained.

Commercial orchards are being established in a few localities, some of which are now coming into bearing. They vary in size from 10 acres to even 100 acres or more. The very remarkable activity, however, along horticultural lines has expended itself, in large part, upon the home orchard. During the last few years, the growing of fruit for the family table has been attempted for the first time in Wyoming, upon thousands of homesteads. New settlers from the states to the eastward come with definite notions of what they will attempt and they are meeting with a substantial degree of success both upon the irrigated and the "dry farms."

The agricultural land along the water-courses naturally were the first areas to be brought under cultivation, since the canals necessary to bring the water to the soils could be easily and cheaply constructed. The bench areas, or uplands, however, have better drainage both for water and air, and are more likely to be free from injurious late and early frosts. These are now being brought under cultivation and are well adapted for fruit-growing, though it should be said they are no better than certain of the bottom lands and foothills locations. Warm, sandy loams in protected places, whether on the stream bank or in the valleys among the foothills, may be depended upon. On the open plains and table-lands, in most parts of the state, it is necessary to provide windbreaks to protect both tree and fruit against stiff storms and desiccating winds.

The great diversity of soil and climate and the differing degree of protection, gives a gradually diminishing list of fruits that are hardy and adapted. Beginning with the most favored localities, tender vegetables, like tomatoes, melons, cantaloupes and sweet potatoes, are grown successfully on a commercial scale. Under these conditions all the hardy fruits that will mature in a growing season of 150 to 180 days are standard. As the lands lie at successively higher elevations and with less favorable exposures or with less natural or artificial protection, the reliable varieties shade down to a few of the so-called "iron-clad" ones. At 6,000 to 8,000 feet, light frosts occasionally occur, even in July and August. It is, however, a matter of common observation that with increasing altitude the effect of frost is less and less marked, so that tender vegetation which goes down under 1° or 2° of frost at sea-level, at 8,000 or 9,000 feet will stand untouched when night temperatures are several degrees below the freezing-point. Potatoes, in the mountain valleys, will bend under the dense hoar-frost night after night without injury. Another physiological phenomenon is borne out by common observation, viz., that plants in the high altitudes "learn to hurry." The identical species that in the lower altitudes take the whole growing season will reach maturity in the successively fewer growing days of the season at higher levels.

During the past few years, the State Board of Horticulture, the State Horticultural Society, and the Superintendent of the Horticultural Experimental Farm have coöperated in compiling a list of the fruits that may be relied upon. This tentative list stands as below. It is to be remembered that Wyoming is, horticulturally speaking, very young and therefore further observation and experiment will no doubt add to and subtract from this.

For altitudes above 6,000 feet.—Apples—Transparent, Duchess, Tetofsky, Wealthy. Crabs—Siberian, Transcendent, Florence. Cherries—Compass cherries only. Plums—Sapa, Opata, DeSoto. Currants—Red Dutch, Fay's Prolific, Champion. Gooseberries—Houghton, Industry. Strawberries—Dunlap, Crescent.

For altitudes above 4,500 and under 6,000 feet.—Apples, fall—Transparent, Duchess, Tetofsky; late fall and winter—Wealthy, Longfield, Patten. Crabs—Transcendent, Whitney, Florence. Pears—Douglas, Idaho, Flemish. Cherries—Compass, Richmond, Plums—Cheney, Wolf, Hanska, Opata. Raspberries—Sunbeam, King, Turner. Currants—Victoria, Red Dutch, White Grape. Gooseberries—Houghton, Industry, Carrie. Strawberries—Dunlap, Bederwood, Warfield, Jessie. Grapes—Beta.

For altitudes below 4,500 feet.—Apples, summer and fall—Transparent, Duchess, Tetofsky, Charlamoff; late fall and winter—Wealthy, Wolf River, Northwestern Greening, Windsor, Fameuse, McIntosh, Banana, Jonathan. Crabs—Transcendent, Whitney, Bailey. Pears—Douglas, Idaho, Flemish. Cherries—Morello, Richmond, Suda, Etopa, Compass. Plums—Wolf, Cheney, Burbank, DeSoto, Sapa, Opata, Hanska. Raspberries—King, Turner, Herbert, Ranere. Currants—Victoria, Red Dutch, White Grape, Champion. Gooseberries—Houghton, Industry, Carrie. Strawberries—Dunlap, Bederwood, Warfield, Gandy. Grapes—Beta, Concord (with protection). Dewberries—Lucretia (with protection).

The state maintains an experimental fruit farm at Lander. The altitude there is about 5,500 feet,—about midway between the lowest and the highest points at which fruit-growing is attempted.

The number of plantings at that farm is 2,420 trees, distributed as follows: Apples, 160 varieties, of which forty-eight have fruited; crabs, twenty varieties, all of which have fruited; pears, fourteen varieties, five of which have fruited; plums, twenty-four varieties, sixteen of which have fruited; cherries, fifteen varieties, five of which have fruited; prunes, two varieties, one of which has fruited; apricots, two varieties, one of which has fruited.

Based upon the results thus far attained, the following list of apples is a suggestion from which planters may select, the arrangement being in the order of hardiness or adaptability to Wyoming conditions: Summer varieties—Transparent, Charlamoff, Linfield, Duchess, Whitney No. 20, Enormous, Utter, Astrachan, Okabena, Hutchins, Hibernal, Patten Greening and Grundy; winter varieties—Wealthy, Peter, Gideon, Fameuse, McIntosh, Northwestern Greening, Pewaukee, Scott, Windsor, York, McMahon, Wolf, Gano.

Trucking is developing satisfactorily in the vicinity of several of the larger towns and cities. Everything, however, is for the home market exclusively, no shipments being made out of the state. Most of the vegetables grown are delivered fresh and direct to the consumer from the producer's wagon. The principal items are lettuce, radishes, peas, beans, beets, carrots, parsnips, turnips, cabbage, cauliflower and, in fact, all of the usual hardy vegetables.

Public-service agencies for horticulture.

The schools for higher education are all located at Laramie. These include the State University, with its several schools and departments, the State Normal School, the Agricultural College, the University Extension Department, and the State Experiment Station. The University was opened in 1887 and the Agricultural College was an integral part of it from the beginning, but the work in agriculture was scarcely organized till 1891, when the Experiment Station was established. Since that time, courses in horticulture have been offered in connection with the work in other departments. At present, the Experimental Fruit Farm at Lander is coöperating closely with College and Station. Only a few horticultural bulletins have been issued, and these are now out of print.

The chief agency for promoting horticultural work in the state is the State Board of Horticulture, organized in 1905. The work of the Board of Horticulture may be divided into two categories: (1) the enforcement of quarantine regulations and the inspection of nursery stock and orchards; (2) the promotion of horticultural development along all lines by the dissemination of information that will help to safeguard the industry, and of literature calculated to encourage the growers. Since the primary object has been to encourage production for home consumption along safe lines, the problems connected with packing and marketing are yet to be considered. The publications of the Board are appearing in two series, the biennial reports, of which five have been issued, and special bulletins.

A State Horticultural Society was organized in 1907. The Society maintains a horticultural department in the "Wyoming Farm Bulletin," a monthly journal issued by the Experiment Station.

Statistics (Thirteenth Census).

The approximate land area of Wyoming in 1910 was 62,460,160 acres. The land in farms was 13.7 per cent of the land area, or 8,543,010 acres. Of this land in farms, the improved land numbered 1,256,160 acres; the woodland, 252,152 acres; and other unimproved land in farms, 7,034,698 acres. The total number of farms in 1910 was 10,987, and the average number of acres to the farm was 777.6. [The total area of the state is 97,914 square miles.]

The leading agricultural crops of Wyoming are hay and forage, and cereals. Hay and forage increased in acreage from 380,769, in 1899, to 585,386 in 1909, when the production was valued at $6,077,354, or 60.6 per cent of the total value of all crops. Cereals increased in acreage from 50,528, in 1899, to 186,947 in 1909, when the production was valued at $2,744,502, or 27.4 per cent of the total value of all crops. The value of the forest products of the farms in 1909 was $104,259, and in 1899, $14,700.

Horticultural crops grown in Wyoming are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $39,806, as compared with $1,470 in 1899. Small-fruits increased in acreage from 37, in 1899, to 106 in 1909, when the production was 96,883 quarts, valued at $13,984. The total acreage of potatoes and other vegetables in 1909 was 11,266, and their value $856,639. Excluding potatoes, the other vegetables increased in acreage from 1,431, in 1899, to 2,933 in 1909, when the production was valued at $332,120. Flowers and plants and nursery products decreased in acreage from 7, in 1899, to 6 in 1909, when the products were valued at $13,960.

The total quantity of orchard-fruits produced in 1909 was 18,586 bushels, valued at $39,774. Apples contributed about 96 per cent of the quantity, the production of apples in 1909 being 17,836 bushels, valued at $37,580. Apple trees of bearing age in 1910 numbered 27,773; those not of bearing age, 84,024. Plum and prune trees of bearing age in 1910 numbered 4,564; those not of bearing age, 7,475. The production of plums and prunes in 1909 was 659 bushels, valued at $1,842. Cherry trees of bearing age in 1910 numbered 919; those not of bearing age, 4,025. The production of cherries in 1909 was 68 bushels, valued at $251. The value of peaches and nectarines, pears, and apricots produced in 1909 was $30, $65, and $6, respectively.

Grapes are of practically no importance, the production in 1909 being only 159 pounds, valued at $32. The vines of bearing age in 1910 numbered 74; those not of bearing age, 1,147. The production of nuts is a negligible quantity.

The most important of the small-fruits grown in Wyoming in 1909 were currants, the acreage increasing from 8, in 1899, to 41 in 1909, when the production was 38,833 quarts, valued at $4,378. Strawberries increased in acreage from 19, in 1899, to 24 in 1909, when the production was 20,895 quarts, valued at $3,820. The production of blackberries and dewberries was 149 quarts, valued at $29; that of raspberries and loganberries 15,213 quarts, valued at $2,910; and that of gooseberries 21,513 quarts, valued at $2,819.

Potatoes, the most important of the vegetables, increased in acreage from 2,809, in 1899, to 8,333 in 1909, when the production was 932,162 bushels, valued at $524,489. The more important of the other vegetables produced in 1909 were: 32 acres of cabbage, valued at $6,289; 16 acres of onions, valued at $3,260; 33 acres of turnips, valued at $2,839; 44 acres of sweet corn, valued at $1,815; 5 acres of tomatoes, valued at $1,324; 9 acres of watermelons, valued at $1,150; and 5 acres of cucumbers, valued at $700. Small amounts of green beans, beets, carrots, celery, parsnips and pumpkins were also grown.

The land devoted to the use of flowers and plants increased from 5 acres, in 1899, to 6 acres in 1909. The area under glass in 1909 was 33,034 square feet, of which 31,584 were covered by greenhouses and 1,450 by sashes and frames. The value of the flowers and plants produced in 1909 was $12,280, as compared with $2,480 in 1899.

The value of nursery products in Wyoming for 1909 was $1,680, as compared with $215 in 1899.

Aven Nelson.

Colorado.

The state of Colorado (Fig. 2527) includes the territory lying between the parallels 37° and 41° north latitude, and between the meridians 102° and 190° west longitude. Its surface is diversified by mountains, high tablelands, plains and valleys, with a range above ocean-level from 3,400 feet on the eastern border to over 14,000 feet in many of the higher peaks. It is traversed in a generally north and south direction by the great Rocky Mountain range, and is thus divided into two well-marked, though unequal, divisions. The main continental divide is supplemented by several well-defined ranges and by numerous mountain spurs, between which at altitudes ranging from 5,000 to 10,000 feet lie four large and several small parks and valleys, which were originally utilized as hay-ranches and for stock-ranges. At present, many of these mountain valleys are the most important farm lands of the state.

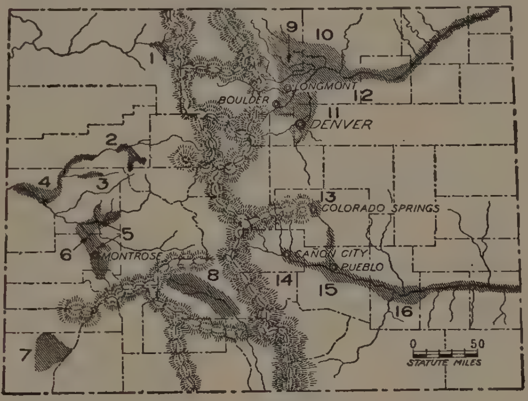
The tillable lands of the state are scattered more or less over the mountainous areas, as well as in the valleys of the Great Plains region. As the rainfall over the tillable area of Colorado is, for the most part, not above 13 to 15 inches, the larger part of the important agricultural production is by irrigation. Irrigation being a necessity, the lands useful for horticultural purposes are those which are reasonably level, either in the bottom-lands or on the mesas bordering the valleys, and which were at one time the bottom-lands along the streams. The first ditches were constructed cheaply and for the irrigation of bottom-lands only. Later, the idea of utilizing the higher mesas gave rise to great canal systems and made productive vast tracts of fertile soil both in the plains district and in the great basins of the mountain districts.

The main horticultural developments of Colorado are shown in the outline map, Fig. 2527, as follows: (1) strawberries; (2) potatoes; (3) dewberries; (4) orchard-fruits; (5) orchard-fruits and potatoes; (6) orchard-fruits, potatoes, onions; (7) apples, peaches; (8) potatoes; (9) apples, cherries, plums; (10) vegetables; (11) orchard-fruits; (12) raspberries; (13) greenhouse interests; (14, 15) fruit and vegetables; (16) apples, cherries, cantaloupes.

Owing to differences in latitude, altitude, and climatic conditions, the irrigable regions of the state are naturally separable into three divisions. These divisions are the Northern, which embraces the drainage basin of the South Platte and its tributaries, including Clear Creek, Boulder Creek, St. Vrain, Big and Little Thompson, and the Cache la Poudre. The Southern, or Southeastern, embraces the valleys of the Arkansas and its tributaries. The Western and Southwestern, which are more or less the same, embrace the valleys of the Grande and its tributaries, the Uncompahgre and Gunnison in Mesa Delta and Montrose counties, and a great tract of land extending from Montrose around the spur of the San Juan Mountains, including the valleys of the San Miguel, Dolores, Mancos, La Plata, Animas, Florida, Pine, Rio Piedra, and the San Juan. These rivers drain the territory included in western Montrose, San Miguel, Dolores, Montezuma, La Plata, and Archuleta counties.

Other horticultural regions that are still largely undeveloped are the valleys of the Yampa or Bear River in northwestern Colorado and the White River in Rio Blanca County.

The apple is the leading fruit of the northern Colorado district. All the standard varieties are grown, though probably there are more Ben Davis trees than any other one variety. The cherry is the fruit of next importance and gives promise of becoming the leader, as the sour cherry is adapted to the conditions in northern Colorado and is more successfully grown without irrigation than any other fruit. The estimated acreage of fruit in this district is 15,000 acres. Plums are more or less successfully grown in northern Colorado. Of these, the so-called native plums, or those varieties derived from *Prunus americana*, are most hardy and successful; many varieties of *Prunus domestica* are also grown.



2527. Colorado, with the parts developed in horticultural products.

In the Southern district the counties most prominent in fruit-culture are Fremont, which is at the base of the mountains in the Arkansas Valley, Pueblo, and Otero. Fremont County is one of the oldest and most important fruit districts of the state. What are supposed to be the oldest orchards of the state are located near Florence. In this district the apple is the most important fruit, followed by the cherry and plum, as in northern Colorado, and some peaches are grown in Otero County by protecting the trees during the winter. This protection is given by laying down the trees and covering with soil. The total area in fruit in the Southern district is approximately 25,000 acres.

In area devoted exclusively to fruit-growing and in importance of the product, the west slope easily leads other parts of the state. The largest solid areas devoted to fruit-growing are in Mesa, Delta, and Montrose counties in the valleys of the Grand, the Gunnison and Uncompahgre rivers. In these districts there is a great range of altitude, as fruit is grown as low as 4,500 feet at Grand Junction and at as high an altitude as 7,000 feet at Paonia and Cedaredge. In the narrow cañon at Palisade is one of the most remarkable peach districts of the country. Here in a cañon with walls on the north 2,000 feet high, peaches are grown at their best. The areas of fruit-production in these districts are rapidly increasing. The Gunnison Tunnel, an irrigation project in the Uncompahgre Valley, furnishes water for 65,000 acres of land. Other ditches and projected canals in the Grand Valley are still more extensive, so that all told, the irrigated area of these three river basins approximates 300,000 acres.

The leading fruit of the west slope, as of other districts, is the apple. All varieties are grown, although the Jonathan, Rome Beauty, Winesap, Gano or Black Ben Davis, are coming to be the leading varieties. Pears are grown extensively in this district, except where the blight has destroyed the trees or made pear-growing unprofitable. Both the sweet and sour cherries are grown successfully. Of these, Montmorency and English Morello are the leaders among the sour cherries and Napoleon and Black Republican, of the sweet cherries. Peach-growing is largely limited to the Palisade and the so-called North Fork districts in the neighborhood of Paonia. The Elberta is at present the leading variety. Plums, both the American and European species, are grown extensively.

The fruit districts of the southwestern part of the state have not developed so rapidly as those of the western slope, largely owing to a lack of railroad facilities. Montezuma County has for several years been renowned for its excellence of fruit, and large plantings are being made there. The area adapted to fruit-growing in this Southwest district, which is from 100,000 to 200,000 acres, is as yet largely undeveloped and will require immense irrigation projects to bring it up to its possibilities of production. The area of the West and Southwest District approximates 65,000 acres planted to fruit.

Owing to the remarkable diversity in altitude, precipitation, soils, temperatures and exposures incident to its mountainous surface, Colorado has developed many peculiarities in horticultural crops. One of the most marked of these is the strawberry-growing industry of the Steam Boat Springs district of the northwestern part of the state. The climate is normally cool and the winter snowfall is heavy, lying on the ground from early fall till late spring. This gives perfect winter-protection to the plants. Their growth during the short, cool growing-season is remarkable. The fruit, which is abundant, large and of good quality, begins to ripen July 1 to 10 and continues well into August. At present there are only a few hundred acres of strawberries in the district, but the planting is rapidly increasing.

In the Plateau Valley, a few miles above Grand Junction, under climatic conditions somewhat similar to those of the Steam Boat Springs district, there has developed a rather unique industry in the way of dewberry-growing. There in the deep, rich, cool soils the dewberry attains a remarkable degree of excellence and productivity. Distance from railroad and the perishable nature of the fruit have prevented this crop from assuming extensive proportions, although the work has been profitable to a few individuals.

The red raspberry has been a profitable crop in various fruit districts of Colorado, particularly in the vicinity of Loveland. The strong, fertile soils, congenial climate, and moisture supplied by irrigation, combine to make a luxuriant growth of vines and heavy yields of fine fruit. In order to avoid the drying and killing effects of the arid winters, the practice is followed of laying down the canes and covering them with soil during the dormant season.

The potato is in point of value, with the possible exception of the apple, the most important of the horticultural crops of Colorado. There are many peculiarities in its adaptability to the conditions of soil and climate and the distribution of its production over the state. The climate and soil of the higher mountain valleys are exceptionally congenial, possibly because they are similar to its habitat in the high altitudes of the Andes Mountains of South America. One species, *Solanum Jamesii*, is native to the mountain plateaus of Archuletta and La Plata counties in southern Colorado. Only a small part of the irrigated land of Colorado, however, is adapted to the growing of potatoes and but relatively small sections outside the high mountain valleys can produce potatoes at all successfully. For some reason, as yet not understood, the potato cannot be depended upon to make tubers on a large part of the best lands of the lower altitude districts. The more important potato-growing areas, in point of total production, are: the Greeley district, with a normal acreage of 35,000 to 40,000 acres, in the plains territory of northern Colorado; the Carbondale district at the junction of the Roaring Fork and the Crystal rivers in Garfield County; the Uncompahgre and North Fork valleys in Montrose and Delta counties; and the San Luis Valley, a mountain valley above 7,000 feet in altitude, comprising more than 3,000,000 acres in the southern part of the state. Other small valleys in the mountain areas are equally important in respect to yields and quality of product. No district in the United States gives greater average yields than are obtained by some of the better growers in these mountain valleys. From 300 to 400 bushels an acre on large fields are not uncommon average yields, and this without the use of any fertilizer. A large part of the available potato lands of these high mountain valleys are as yet undeveloped and the acreage planted to this crop is rapidly increasing.

The cantaloupes grown at Rocky Ford and other points along the Arkansas Valley in Colorado have brought that district to the attention of the whole country. The natural adaptability of the soils and climate is such that the cantaloupe has become the leading "hoed" crop in general rotation with grain and alfalfa, over a large area of land. Thousands of cars of cantaloupes are shipped each year from the Rocky Ford territory and the market extends over all parts of the United States. The cantaloupe is also grown, for distant markets, in the Grand Junction district on the West Slope and, for local markets, in the Greeley district.

Cabbage-growing, on the East Slope, for distant markets is an industry of increasing importance. The northern Colorado irrigated district, with Greeley as a center, is now producing heavy yields of cabbage that are shipped to markets in the cotton- and grain-belt states. Wakefield and Winnigstadt are grown for early shipments, while Scott's Cross, Flat Dutch and Ballhead are the most common late varieties. The high-altitude mountain districts are also well adapted to the growing of heavy yields of good-quality cabbage, but the transportation facilities are such that no considerable industry in cabbage-growing has been developed.

The onion is grown, not only for home use and local markets, but its production as a crop for shipping into distant markets has in several districts become of considerable commercial importance. The districts where onion-growing has become established as a permanent industry are Greeley, Pueblo and Cañon City on the East Slope, with Olathe as a center in the Uncompahgre Valley in the western part of the state.

One of the vegetable crops to which the irrigated lands of Colorado are admirably adapted is celery. This vegetable is being grown for local consumption in all parts of the state. The growing of celery for distant markets is steadily on the increase, and is being found generally profitable, in the region above Denver, Pueblo and near other towns where stable manure can be procured for fertilizing the land.

Peas grow well in all the higher parts of the state. In the San Luis Valley, the Canada field pea is grown extensively as a field crop for feeding sheep and hogs. The garden pea is grown for the canning industry in the vicinity of Longmont, Loveland, Greeley and Ft. Lupton, at which places canneries are located. Other canning crops are also grown in these same districts, as beans, tomatoes and the like, but the pea is by far the most important.

Another horticultural crop that gives promise of future importance in Colorado is cauliflower. This vegetable, like the cabbage, thrives better as the altitude becomes higher, and is grown to perfection at 7,000 to 9,000 feet. Growers in the high altitudes frequently grow individual "flowers" weighing from six to ten pounds, perfect in every way, and many growers claim that a yield of 20,000 pounds an acre is not difficult to obtain.

The florist and forcing industries of the state are limited for the most part to the growing of flowers and vegetables for local trade only. Each city or small town has one or more greenhouse plants and the larger cities of Denver, Pueblo and Colorado Springs have extensive forcing and greenhouse establishments.

The larger part of the flowers and shrubs common to the northern sections of the United States must be included in the list of outdoor plants for Colorado. Their use, however, is limited largely to the home and town or city parks. Most biennials and herbaceous perennials that are grown in the North grow well in Colorado at the altitude of Denver and in many cases at much higher altitudes, though some shrubs need more or less winter protection to prevent killing back to the ground. Many ornamental shrubs and trees that are native to the mountains of Colorado are used as ornamentals both in Colorado and elsewhere. The arid lands of the plains and mountains abound with many beautiful trees, shrubs and plants which would be of value for transplanting as ornamentals but for their tendency toward slow growth, which has made it possible for them to exist under the arid conditions of that climate.

Most vegetables, fruits and flowers that are adapted to a cool climate are at their best in the larger part of the irrigated sections of Colorado. Eighty-five per cent of all the days of the year are cloudless and in the cool dry air, fungi are not generally troublesome as compared with the more humid parts of the United States. Plants that require a warm climate or a long season, as the tomato, cucumber and sweet potato, are grown successfully in the warmer parts of the state, but for the most part such crops have not made the marked showing that has been made by the fruits and vegetables adapted to a cooler climate.

Few individuals stand out prominently as having been especially instrumental in the development of Colorado horticulture. Jesse Frazier, of Florence, was one of the first men of the state to plant apples extensively. In 1864 he brought trees from Missouri and his orchard still bears evidence to the care and skill with which it has been handled. Capt. B. F. Rockafellow, of Cañon City, whose orchard of apples and cherries, planted about forty years ago, is still producing profitable crops, was also instrumental in the development of fruit-growing in that district. J. S. McClelland, of Fort Collins, was one of the earliest and most successful nurserymen and orchardists of the state. His trials of varieties and methods of culture did much to make fruit-growing a success in that region. W. S. Coburn, of Paonia, who was for several years president of the State Horticultural Society, was one of the first of the West Slope growers to plant heavily, as was also Mr. Steele who planted one of the first orchards in the Grand Junction district.

Public-service agencies for horticulture.

The development of all the different horticultural activities in a climate totally different from that of the older parts of the country, necessitated the solution of many new problems. From time to time public-service agencies have been created to take care of these problems. In 1879 an act of the State Legislature created a Board of Agriculture whose duties were largely to organize and control a State College of Agriculture. The same year, the College was established at Fort Collins in northern Colorado, according to the Land-Grant Act of Congress of 1862. The College, together with the State Agricultural Experiment Station which was organized in 1887 and established at the same place, has done much for the horticultural interests of the state. The numbers of the horticultural staff of the College and Station has varied with the support given the institution by the state. At present it comprises four men, all located at Fort Collins. Up to the present time fifty-six bulletins have been issued by the Experiment Station that relate to or have a direct bearing on the horticultural problems of Colorado.

Instruction in horticulture is given among the farmers of the state through the agency of farmers' institutes, and one-week short courses in horticulture are held in the various horticultural centers of the state. Horticulture is also taught in many of the graded and high-schools of Colorado.

A State Horticultural Society was organized in 1880 which is still active. In 1903 a bill was passed by the Colorado Legislature establishing a Board of Horticulture, the object of which was similar to that of a State Horticultural Society. The 1913 Legislature abolished this Board and created in its stead the office of State Horticulturist. By the provisions of this act, the Horticulturist of the State College is State Horticulturist and his duties are to assist the horticulturists of the state by giving them advice or investigating such problems as may arise.

An act of the Legislature of 1909 made the Entomologist of the State Agricultural College, ex-officio, State Entomologist. The duties of this office are to inspect all nursery stock grown or shipped into the state and to destroy or reject all found infested with injurious insects or fungous diseases.

Statistics (Thirteenth Census).

The approximate land area of Colorado is 66,341,120 acres. Of this area, there are 13,532,113 acres in farms, or 20.4 per cent of the land area; 31.8 per cent of the farm land, or 4,302,101 acres, are improved; 891,698 acres are in woodland, and the unimproved land in farms totals 8,338,314 acres. The number of all the farms in 1910 was 46,170. The average acreage to the farm was 293.1. [The total area is 103,948 square miles.]

The leading agricultural crops are cereals, hay and forage, sugar crops, and broom-corn. The acreage of cereals in 1909 was 1,057,905, as compared with 525,299 in 1899, showing an increase of 101.4 per cent. The value of the cereals in 1909 was $14,787,519. Hay and forage in 1909 occupied 1,285,064 acres, as compared with 952,214 acres in 1899, an increase of 35 per cent. The value of hay and forage produced in 1909 was $17,282,276. Sugar crops are significant in that the acreage has shown an increase of 9,615.7 per cent in the period from 1899 to 1909. The acreage in 1909 was 111,251; in 1899, 1,145. The value of the sugar crops in 1909 was $6,104,672; in 1899, $27,818, showing an increase in value of 21,844.8 per cent. The acreage of broom-corn in 1909 was 5,631; in 1899, 1,241, showing an increase of 353.7 per cent. The value of forest products from the farms in 1909 was $305,719; in 1899, $113,055.

The leading horticultural crops of the state are fruits and nuts, vegetables, including potatoes, sweet potatoes and yams, flowers and plants and nursery products, and small-fruits. The value of all fruits and nuts in 1909 was $4,680,142, or 9.2 per cent of the total value of all crops grown; vegetables in 1909, including potatoes, sweet potatoes and yams, were valued at $6,058,939, or 11.9 per cent of the total value of all crops. Flowers and plants and nursery products in 1909 were valued at $540,775 as compared with $264,415, their valuation in 1899. The acreage of small-fruits in 1909 was 2,829, an increase of 20.5 per cent since 1899, and their value $398,836.

Apples are the most important of the orchard-fruits, with peaches and nectarines ranking second. In 1910, the apple trees of bearing age numbered 1,688,425; those not of bearing age, 1,972,914. The production of apples in 1909 was 3,559,094 bushels, valued at $3,405,442. The peach and nectarine trees of bearing age in 1910 numbered 793,372; those not of bearing age, 606,001. The production in 1909 was 692,258 bushels, valued at $764,561. The other orchard fruits and their production and value of their products in 1909 follow: pears, 132,536 bushels, valued at $210,685; plums and prunes, 81,539 bushels, valued at $81,354; cherries, 88,937 bushels, valued at $173,895; apricots, 11,403 bushels, valued at $15,658.

The number of grape-vines of bearing age in 1910 was 254,292; those not of bearing age, 101,332. The production in 1909 was 1,037,614 pounds, an increase of 77 per cent over the production in 1899. The value of the grape products in 1909 was $28,026.

The quantity of nuts produced in 1909 was 7,796 pounds, valued at $324. The nuts included in this grouping are Persian or English walnuts, black walnuts, almonds, chestnuts, pecans, Japanese walnuts, hickory-nuts, filberts, hazelnuts, and others.

Of the small-fruits grown, raspberries and loganberries are the most important in value, with strawberries second. Considered from the standpoint of production this order is reversed. The acreage of strawberries in 1909 was 1,326, producing 1,674,923 quarts of berries, valued at $156,059. The acreage of raspberries and loganberries in 1909 was 801, producing 1,650,785 quarts of berries, valued at $156,668. Other small-fruits, their production and value were, in 1909: blackberries and dewberries, 227,598 quarts, valued at $27,833; currants, 493,726 quarts, valued at $39,935, and gooseberries, 247,956 quarts, valued at $18,341. The acreage in each case in 1909 was, 195, 226, and 122 acres respectively.

Of the vegetables, the potatoes, sweet potatoes and yams were the more important. The acreage of the potatoes, sweet potatoes and yams in 1909 was 85,860, an increase of 94.7 per cent since 1899. The production was 11,783,501 bushels, valued at $3,709,305. Other vegetables in 1909 occupied 32,422 acres, producing products valued at $2,349,634. The acreage and value of the more important vegetables in 1909 follow: 2,568 acres of cabbage, valued at $180,964; 3,970 acres of cantaloupes and muskmelons, valued at $334,291; 357 acres of celery, valued at $110,114; 577 acres of onions valued at $64,665; and 1,646 acres of tomatoes, valued at $138,339. Other vegetables grown are asparagus, green beans, sweet corn, cucumbers, lettuce, green peas, turnips and watermelons.

The acreage devoted to the growth of flowers and plants in 1909 was 154; in 1899, 137. The area under glass was, in 1909, 1,340,824 square feet, of which 1,244,425 were covered by greenhouses and 96,399 by sashes and frames. The total value of flowers and plants produced in 1909 was $468,685.

The acreage occupied by nursery establishments was 241 in 1909, as compared with 497 in 1899, showing a decrease of 51.5 per cent. The value of the nursery products, however, increased 9.3 per cent during that time, from $65,936 in 1899 to $72,090 in 1909.

E. R. Bennett.

New Mexico.

New Mexico (Fig. 2528), though rich in mineral resources and in its salubrious climate is, nevertheless, an agricultural commonwealth. Because of its location in the southwestern part of the United States, it is sometimes thought by persons not familiar with its topography and other physical conditions that it must have a tropical or at least a semi-tropical climate. This would probably be true if it were not for its great elevation. The high altitude gives New Mexico a temperate zone climate suitable for temperate zone fruits and other plants. New Mexico is mostly a country of mountains, valleys and prairies. Spurs of the Rocky Mountain system extend from north to south through the central and western parts of the state. The extreme eastern part, with an altitude varying from about 3,000 feet in the extreme southeast corner to about 5,000 feet in the northeast part, partakes more of the nature of a prairie country. This part has a larger average rainfall than the central and western agricultural valleys and during the last ten years it has developed extensively into a dry-farming section. The rainfall, however, is not enough to insure satisfactory results in the growing of fruits and vegetables, particularly on a commercial scale.

Some of the higher horticultural districts in which many fruits and vegetables succeed, range from 6,000 to 7,500 feet. This is the altitude of such places as Santa Fe, Mountain Park, Cimarron, Las Vegas and Taos; while the Roswell, Carlsbad, Las Cruces, Socorro, Albuquerque and Deming districts, in which horticulture has developed into a high state of cultivation, have altitudes varying from 3,100 at Carlsbad to 5,000 feet at Albuquerque. Perhaps the average height of New Mexico valleys and irrigable areas varies from 4,000 to 5,500 feet.

New Mexico is a large state, ranging fourth in size. On account of its being practically in the center of the arid section of the United States, however, it is impossible to utilize all of its large acreage for agricultural purposes. Only the places which can be irrigated, in the extreme eastern part of the state and any parts in between the mountains which get a fairly large amount of rain can be brought into cultivation. Out of its large acreage, it is now pretty well known that about 3,500,000 acres are irrigable and that 10,000,000 acres are claimed to be adaptable for dry-farming crops.

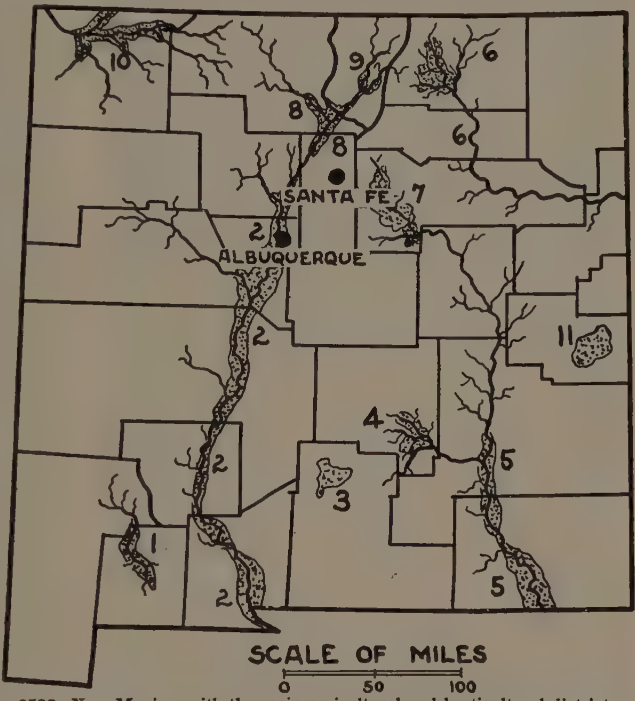
Since practically all of the truck and fruit crops have to be raised under irrigation, this discussion will be limited to those agricultural districts which are being developed by irrigation. Wherever water for irrigation may be had, either from rivers, reservoirs, springs, or wells, it is reasonably safe to expect good results from certain horticultural plants. Almost every county in the state has one or two districts in which horticultural operations may be conducted very successfully. The accompanying map gives the larger fruit-growing districts in the state, eleven in number. District No. 1 takes in part of Grant and Luna counties; district No. 2 takes in all of the Rio Grande Valley from Santa Fe down to the Texas line; district No. 3 is found mostly in Otero County around Alamogordo, extending somewhat into the mountains; district No. 4 includes all of the little mountain streams in Lincoln and Chaves counties; district No. 5 includes all of the Pecos Valley; district No. 6 takes in all of the mountain streams in northern New Mexico, mostly in northwestern and southern Colfax County; district No. 7 is found in Mora and San Miguel counties, in the southern and northwestern parts; district No. 8 includes parts of Santa Fe and Rio Arriba counties along the Rio Grande Valley and mountain streams; district No. 9 includes the old Taos Valley and the little mountain streams in Taos County; district No. 10 is located in the northwestern corner of New Mexico, mostly in San Juan County; district No. 11 is the Portales district in Roosevelt County, being developed by pumping.

At the present time the leading horticultural industries are fruit-growing and truck-gardening, fruit-growing being the leading and most important one. The horticultural districts in New Mexico, on the whole, are better suited for fruit-growing than for truck crops. The leading fruits are apples, peaches, pears, plums, and grapes. Some cherries and quinces are also grown. In the last ten years, much interest has developed in apple-growing. Many large apple orchards have been and are being planted in practically all of the horticultural districts. From all indications, it is safe to say that New Mexico will yet be an apple-producing state, though pears and peaches will also be grown on a large scale. The principal apple-growing sections at the present time may be found at Roswell, Dexter, Artesia, Hope, Mountain Park, Three Rivers, Cimarron, Taos, Española, Santa Fe, Albuquerque, Socorro, Las Cruces, Mesilla Park, Aztec, and Farmington.

New Mexico has many different kinds of climate and soil and for this reason it is impossible to make any definite statements as to the adaptability of varieties to all of the horticultural districts. As a matter of fact, it is found that certain varieties do better in certain parts of the state than in others. The most widely grown varieties in the state seem to be, at the present time, Red June, Early Harvest, Yellow Transparent, Maiden's Blush, Ben Davis, Mammoth Black Twig, Gano, Black Ben Davis, Winesap, Jonathan, Arkansas Black, Rome Beauty, and White Winter Pearmain. In the lower and warmer parts of the state, the Jonathan, King David, Ben Davis, Gano, Black Ben Davis, Winesap, Mammoth Black Twig, and Arkansas Black are among the leading varieties. In the cooler and higher altitudes these same varieties are popular, with the exception of the Mammoth Black Twig, King David and Arkansas Black. In place of these, Stayman Winesap, Delicious, Grimes' Golden and White Winter Pearmain are used. In the lower and warmer valleys, the Delicious apple varies very materially from the original Delicious type.

There are not so many pears being grown as there are apples, but in some of the horticultural valleys there is a marked interest being taken in growing this fruit. At the present time in district No. 2, particularly in the Mesilla Valley, many orchards are being planted to the Bartlett pear. So far this fruit has not been threatened by the dreaded pear-blight. The climatic and soil conditions seem to be particularly well suited to the pear in some of the lower and warmer districts. In 1914 the first two carloads of fancy Bartlett pears were shipped to New Orleans markets from young orchards in district No. 2. This industry promises to become a very important one. Aside from the Bartlett, the Doyenne d'Ete, Howell, Clapp Favorite, Flemish Beauty, D'Anjou, Winter Nelis, and Winter Bartlett comprise a good list of varieties of pears to plant in New Mexico. So far the Bartlett orchards have not shown any indications of trouble due to self-sterility of the variety. However, to be on the safe side, there should be at least two varieties used with the Bartlett, if for no other purpose than for cross-pollination. These varieties may be the D'Anjou, the Winter Bartlett, or Winter Nelis.

The peach probably holds second place among the orchard-fruits grown in the state at the present time. In the lower and warmer valleys this species grows very well and blooms very heavily. The greatest drawback to the peach is the injury to the blossoms or young fruit from the late spring frosts. This injury may be mitigated to some degree by the proper and judicious use of smudge pots. Peach-growing is conducted on a comparatively large scale in districts Nos. 2, 3, 5, and 10. The largest commercial peach orchards are to be found at Carlsbad, Tularosa, Las Cruces and Farmington. Most of the varieties that have been tried seem to do well, but the following is a list which has become somewhat popular and the varieties are given in the order of their ripening,—Alexander, Hynes' Surprise, Texas King, Mamie Ross, Carman, Elberta, Late Crawford, Crothers, and Salway. The Alexander and Hynes' Surprise are the latest-blooming varieties and are the earliest to ripen. Because they are very late in blooming they are, as a rule, the surer bearers. The Texas King, Mamie Ross and Crothers are medium late in blooming and, as a rule, are sure bearers. In this class, so far as blooming is concerned, may be listed the Late Crawford and Salway. The earliest blooming commercial variety is the Elberta, and this peach fails oftener to bear than any other variety. Experiments show that it is not safe to count on more than one full crop in five years. The new peach, the J. H. Hale, which is very promising in many respects, appears to be an early bloomer, blooming as early, if not earlier, than the Elberta.



2528. New Mexico, with the main agricultural and horticultural districts. (Irrigated districts.)

The apricot is one of the hardiest and most resistant fruit-trees to unfavorable conditions, but all of the varieties tried bloom entirely too early to escape the late spring frosts, and for this reason it is not considered a profitable fruit to grow.

Districts Nos. 1, 2, 3, 4, 5, 8, and 10 seem to be well suited for plum-growing. Almost any variety of plums seems to grow well in most of these districts. Varieties of the European group are best suited for New Mexico conditions, as they are extremely late bloomers. As a rule they bloom as late, and in some cases later, than the apples. Coe's Golden Drop, Jefferson, Imperial Gage, Green Gage, Pond's Seedling, Yellow Egg, Shippers' Pride, Robe de Sargent, German prune and French prune are among the leading varieties. The Japanese plums bloom entirely too early and for this reason they can hardly be expected to bear a satisfactory crop more than once in every five years. In this group of plums may be found some of the best eating and early ripening varieties. The Japanese plums are not considered profitable to grow. There are a number of satisfactory native plums. In this group may be found a wider range of blooming periods than in any other group. A few of the later blooming varieties are the Wild Goose, Omaha, Wayland, Golden Beauty and Victor.

Cherries are not grown on a large scale at the present time, though trees of the sour varieties may be found growing in almost all of the fruit-growing districts. The sweet cherries do not seem to do nearly so well as the sour varieties. The Ostheim, Early Richmond, Montmorency and English Morello are some of the more popular sour cherries. The cherry trees, as well as the plum trees, are comparatively short-lived and in the lower and warmer valleys they are more or less subject to sun-scald.

The area devoted to grapes is not very large, though favorable climatic and soil conditions may be found in different horticultural districts. In the cooler and higher altitudes, the conditions are favorable for the American varieties, though very few American grapes are, at the present time, being grown in New Mexico. These varieties may be grown very satisfactorily in districts Nos. 1, 4, 5, 6, 7, 8, 9, 10, and 11. More grapes have been grown in district No. 2 than in all of the other districts put together. Varieties of the vinifera grape seem to be very satisfactory. Large vineyards are to be found in this locality, mostly of the old Mission grape. During later years, Thompson's Seedless, Chasselas, Black Hamburg, Muscat of Alexandria, Purple Damascus, Black Cornichon, Tokay, and Black Ferrara have been added to these plantations. The European grape grows and bears very satisfactorily, but it is somewhat tender and is liable to be winter-killed occasionally.

Much has been said about growing the date palm and figs in New Mexico. The winter temperatures are much too low, even in the warmer and lower valleys of the state, for the date palm to grow. The plant makes a good growth in the summer but it cannot stand the winter temperatures. The fig is a little more hardy and will stand zero temperatures frequently in the lower and warmer valleys. While the fig tree cannot be grown on a commercial scale, a few specimens may be planted in home plantations in southern New Mexico. The best results from these trees can be secured when they are planted either on the south or east side of a house or wall. When planted on the north or west side of the house, they are more liable to be winter-killed.

The small-fruits can be grown very satisfactorily. At the present time there are no large plantations in the state. On the whole, the best small-fruits are to be found growing in the higher districts. Strawberries, gooseberries and currants do well in the lower and warmer valleys and at the present time there is considerable interest being taken in strawberry-culture.

While, up to the present time, most of the horticultural industries have been the growing of fruits and vegetables, nursery and floricultural work is now attracting considerable interest. In the last two or three years a few nurseries have been started, mostly in district No. 5. Not much attention has been given, so far, to nut-culture in this state, though a few small experimental orchards of pecans, as well as a number of almond and English (Persian) walnut trees, have been set out.

Many vegetables can be grown satisfactorily. Among the most promising ones are asparagus, cantaloupes, melons, tomatoes, onions, sweet potatoes, red peppers, cauliflower, cabbage, spinach, peas, and beans. Because of the great distance to large vegetable markets, it is necessary to grow those vegetables which are less perishable and can stand shipping a long distance. Spinach in districts Nos. 1, 2, 3, and 5, can be grown very satisfactorily, particularly in the southern parts of districts Nos. 2 and 5. From there it may be shipped to the northern and eastern markets during January, February and March. Spinach in these districts yields from two to four tons an acre.

Sweet potatoes are grown all over the state, wherever irrigation is possible. Such varieties as the Southern Queen and Red and White Bermuda grow very large and produce from 15,000 to 20,000 pounds an acre. The Yellow Nansemond and Yellow Jersey are the best commercial varieties, but they are not so large, yielding about 15,000 pounds an acre.

One of the most promising vegetables that will stand long shipments is the onion. Most of the varieties of onions will grow well; in the higher and cooler districts, varieties of the American type, such as the Brown Australian, Yellow Danvers, Red Weathersfield and White Globe are the most suitable. These varieties are more popular in the local markets than the larger growing kinds, but are not considered so profitable when they have to be shipped to eastern markets. On the other hand, the large-growing and mild varieties, such as the Giant Gibraltar, White Tripoli, and Denias are very suitable for the warmer and lower valleys, particularly in districts Nos. 1, 2, 3 and 5. The Denia onion is being grown in fairly large quantities in these districts.

Chile, or pepper, is a vegetable that has been grown for many years by the Mexican gardeners. It does exceedingly well, particularly in the lower and warmer valleys. The season in the higher altitudes is not long enough for it to ripen satisfactorily. Under favorable conditions it will produce a very large crop. The chile may be used in the green stage or in the red ripe form. It can also be canned in the green stage. The ripe chile may be used in the pod or powder form.

Tomatoes are grown rather extensively in districts Nos. 1, 2, 3 and 5. At Lakewood there is a tomato cannery, which is putting up some very good tomatoes. In the higher altitudes the season is not long enough for tomatoes to ripen satisfactorily.

Many other vegetables can be grown, and many of the more perishable ones are grown by the local truck-growers for local or nearby markets.

One of the first crops that the new farmer usually tries to grow, and the one that he first fails with, is the Irish potato. Unless he is at an altitude of about 7,000 to 8,000 feet, he is not likely to succeed very satisfactorily in the growing of Irish potatoes. For one reason or another, Irish potatoes do not produce satisfactory yields in the lower and warmer parts of the state. The best potato-growing districts in New Mexico are found in the higher and cooler parts. New Mexico grows a large amount of potatoes at these higher altitudes, but practically none is grown in the lower and warmer valleys.

The Catholic priests first set out plantations of Mission grapes up and down the Rio Grande Valley in the early periods. Later such early settlers as T. J. Bull, Thomas Casad, Rafael Ruelas, Rafael Bermudas and Roman Gonzalez were prominent figures in the development of horticulture in district No. 2, while the late Archbishop Lamy and Gaspar Ortiz, James J. Johnson and Major Sena were among the early settlers to take much interest in the horticulture of district No. 8; and W. L. Thomson, and A. Ancheta were the pioneers in horticulture in district No. 1. The first one to start fruit-growing in district No. 5 was the late J. J. Hagerman who became the largest apple-grower in the Pecos Valley.

Public-service agencies for horticulture.

The Land-Grant Agricultural College is located in the Mesilla Valley in south-central New Mexico near Las Cruces, at State College. It was established in 1889. There are four instructors in horticulture on the teaching staff.

The United States Experiment Station is located at the same place as the College. There are eighteen on the station staff.

There are no special schools in the state where teaching in horticulture is undertaken. Some elementary horticulture is taught in some of the high-schools of the state.

Through the Experiment Station and the Extension Department a large amount of extension work in horticulture is going on all over the state.

There has been very little interest taken in the state relative to the inspection of trees for insects and diseases, though there is a state law providing for this work.

There has not been much interest in the state in horticultural organizations. In 1900 a horticultural society was organized with its headquarters at Santa Fe. At the present time there are boards of horticulture in San Juan and Chaves counties.

Statistics (Thirteenth Census).

The approximate land area of New Mexico in 1910 was 78,401,920 acres. The land in farms was 11,270,021 acres, or 14.4 per cent of the land area. Of this land in farms, 1,467,191 acres were improved; 1,491,025 were woodland; and 8,311,805 acres, other unimproved land. The number of all the farms in the state in 1910 was 35,676 and the average acreage to the farm 315.9. [The total area is 122,634 square miles.]

The leading agricultural crops of the state are hay and forage and cereals. The acreage occupied by hay and forage increased from 87,358 in 1899 to 368,409 in 1909, when the production was valued at $4,469,709, or 50.1 per cent of the total value of all crops. Cereals increased in acreage from 96,402 in 1899 to 218,037 in 1909, when the production was valued at $2,382,996, or 26.7 per cent of the total value of all crops. The value of the forest products of farms in 1909 was $253,822, as compared with $34,268 in 1899.

Horticultural crops produced in New Mexico are fruits and nuts, small-fruits, vegetables including potatoes, and flowers and plants and nursery products. The value of fruits and nuts produced in 1909 was $536,165, as compared with $231,211 in 1899. Small-fruits increased in acreage from 48 in 1899 to 66 in 1909, when the production was 76,532 quarts, valued at $9,335. The total acreage of potatoes and other vegetables increased from 5,203 in 1899 to 14,660 in 1909, when the production was valued at $820,497. Excluding potatoes, the acreage of vegetables increased from 4,034 in 1899 to 8,219 in 1909, when the production was valued at $567,154. The production of flowers and plants and nursery products in 1909 was valued at $40,303.

The total production of orchard-fruits in 1909 was 504,059 bushels, valued at $519,677. Apples were the most important of the orchard-fruits, the production in 1909 being 417,143 bushels, valued at $420,536. The number of apple trees of bearing age in 1910 was 542,528; those not of bearing age, 914,254. Peach and nectarine trees of bearing age in 1910 numbered 136,191; those not of bearing age, 184,466, and the production in 1909 was 32,533 bushels, valued at $37,195. Pear trees of bearing age in 1910 numbered 37,220; those not of bearing age, 100,201, and the production in 1909 was 29,435 bushels, valued at $29,688. Other of the orchard fruits produced in New Mexico were: 15,528 bushels of plums and prunes, valued at $17,054; 6,384 bushels of cherries, valued at $10,684; 2,379 bushels of apricots, valued at $3,446; and 657 bushels of quinces, valued at $1,074.

Grapes and nuts are of comparatively little importance in New Mexico. The production of grapes in 1909 was 425,415 pounds, valued at $16,101; and that of nuts, 1,498 pounds, valued at $195. However, the nut industry seems to be on the increase, since the total number of nut trees of bearing age in 1910 was 503, while those not of bearing age numbered as many as 5,199.

Strawberries are the most important of the small-fruits in New Mexico. The acreage increased from 9 in 1899 to 20 in 1909, when the production was 35,634 quarts, valued at $4,086. The production of the other small-fruits in 1909 was: 10,089 quarts of blackberries and dewberries, valued at $1,698; 10,222 quarts of raspberries and loganberries, valued at $1,581; 14,800 quarts of gooseberries, valued at $1,348; 5,523 quarts of currants, valued at $591; and cranberries to the value of $10.

The acreage of potatoes increased from 1,122 in 1899 to 6,230 in 1909, when the production was 295,255 bushels, valued at $234,636. Sweet potatoes and yams increased in acreage from 47 in 1899 to 211 in 1909, when the production was 13,831 bushels, valued at $18,707. Other vegetables of importance produced in New Mexico in 1909 were: 491 acres of cantaloupes and muskmelons, valued at $36,095; 260 acres of green peppers, valued at $17,228; 106 acres of cabbage, valued at $15,034; 287 acres of watermelons, valued at $13,978; 49 acres of celery, valued at $13,500; 97 acres of onions, valued at $8,640; and 24 acres of asparagus, valued at $7,660. Other vegetables produced were green beans, sweet corn, squash, tomatoes, and turnips.

The acreage devoted to the production of flowers and plants increased from 5 in 1899 to 8 in 1909, when the production was valued at $31,121. The total area under glass in 1909 was 87,054 square feet, of which 59,752 square feet were covered by greenhouses, and 27,302 by sashes and frames. The acreage devoted to nursery products decreased from 32 in 1899 to 24 in 1909, when the value of the nursery products was $9,182, as compared with $5,753 in 1899. FABIAN GARCIA.

Arizona.

Arizona (Fig. 2529) is divided nearly equally into two climatic parts by a diagonal line running from northwest to southeast through the state. The region north and east of this line consists largely of plateaus, 5,000 to 8,000 feet above sea-level, diversified by isolated mountains and cut by eroded cañons, including the Grand Cañon. The southwestern half of the state is of comparatively low elevation and is crossed from northwest to southeast by a succession of low mountain chains and wide valleys.

Nearly the whole drainage of Arizona passes by way of the Colorado River to the Gulf of California. The little Colorado drains the northeastern plateau into the Grand Cañon, while the Gila River collects the drainage of the central and southern parts of the state and joins the Colorado just above Yuma.

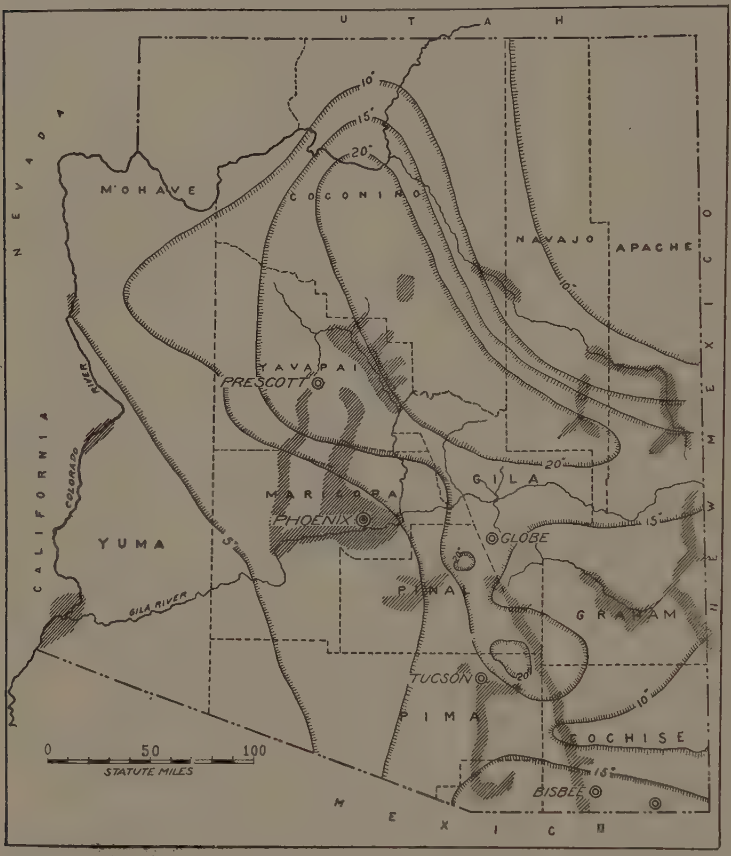
In general, the climate of Arizona combines low rainfall with a very high percentage of possible sunshine, a long hot season, frosty minimum temperatures in winter, and low humidity. With respect to temperature and seasons, the state may be divided into two distinct regions: The northeastern elevated half is comparatively cool, with frostbound winters and temperate summers; the southwestern, and lower, half is arid, subtropical, with long hot summers, but with moderate frosts in winter.

With the help of irrigating waters, temperate-region crops are grown in the northeastern section, while a combination of temperate-region crops in winter and of subtropical crops in summer are grown in the southwestern section.

The daily range of temperature is great, averaging about 30° F., and occasionally reaching as much as 50° F. Relative humidities of less than 10 per cent occur in June; 80 per cent of possible sunshine occurs during the year; average wind-movement ranges from 2 to 3 miles an hour at lower altitudes to 6 to 7 miles at higher altitudes; and the maximum average annual evaporation of 86.51 inches has been observed at Tucson.

The average yearly precipitation in Arizona ranges from 3 to 5 inches along the Colorado River in the west, to as much as 35 inches in the form of rain and snow in the high mountain ranges of the state. The comparatively abundant precipitation of the highlands of Arizona gives rise to numerous never-failing streams, which converge to form the Little Colorado, Salt and Gila rivers. These streams finally empty into the Colorado River of the West, which derives its main flow from the distant watersheds of Colorado, Utah and Wyoming. The Salt, Gila, and other smaller streams, as they flow westward through the arid plains bordering upon the Colorado River, gradually evaporate, or are absorbed, and finally become intermittent in character, floods reaching their mouths only at infrequent intervals.

Numerous storage sites exist which are gradually becoming utilized for the storage of flood-waters, and the ground-waters of the region are being rapidly developed by means of pumping-plants and artesian wells.



2529. Arizona, showing the areas of horticultural development.

In a region where the rainfall is so inadequate for the irrigation of the entire area, horticultural pursuits can only be developed under the constant streams of higher Arizona, and the never-failing Colorado; where flood-waters can be stored, or where ground-waters are available. Only in higher or more favored areas is it possible to cultivate orchards or gardens, depending upon rainfall only. The horticultural districts of the state, therefore, are located almost entirely according to available irrigating water-supply. These districts, so far as they are at all developed, are indicated upon the accompanying map.

Irrigation was first practised at favorable points throughout Arizona by prehistoric peoples, the ruins of whose dwellings and ditches yet exist. Among the crops cultivated by the Indians, are quick-growing varieties of Indian corn, native beans, squashes, pumpkins, martynias, and, in former times, probably, cotton and tobacco. Following the Indians came the Spaniards, from Mexico, who established themselves in the Santa Cruz Valley early in the eighteenth century. The Jesuits at their missions introduced Old World crops, including barley, wheat, apricots, cotton, dates, figs, grapes, melons, olives, onions, citrous fruits, peaches, pears, pomegranate, quinces and vegetable crops.

With the advent of Americans, dating from the Gadsden Purchase in 1854, agricultural and horticultural developments have been rapid, especially in irrigated parts of the state. Improved varieties of the crop-plants introduced by the Jesuits have been developed in large number, and in addition some crops new or previously little known have been imported, among them, alfalfa, apples, sugar-beets, the sorghums, cowpeas, eucalypts, millets, oats, plums, sweet and Irish potatoes, strawberries, tomatoes, and other fruits and vegetables.

Horticulturally, the state is divided into the northeastern elevated portion, best suited to deciduous fruits, summer vegetables and those ornamentals common in temperate climates; and the southwestern half of the state, of low altitude and higher temperatures, in which may be grown those subtropical plants which resist mild frosts and in which winter-growing vegetables and heat-resistant ornamentals thrive.

In the northeast, the leading horticultural products are apples, peaches, pears, plums and grapes. Strawberries, blackberries and a wide range of vegetable crops may also be grown, chiefly under irrigation. The most important of all horticultural crops at the present time is apples, which thrive vigorously at altitudes of 3,000 feet and above. The principal apple-growing districts are irrigated from the Gila River in Graham County and from the Verde and its tributaries in Yavapai County. Occasional orchards are scattered at higher altitudes throughout the state.

In the southwest, a great variety of subtropical and temperate-region crops are possible. Among the more distinctly subtropical plants, resistant to both heat and mild frost, are apricots, dates, eucalypts, figs, olives, oranges, pomelos, lemons, pomegranates and quinces; while many plants common to more temperate regions may be adapted to these lower altitudes, such as grapes, peaches, pears, plums, strawberries, and many vegetables which may be grown during the cooler fall, winter and spring seasons. Among the most important horticultural features of the southwestern half of Arizona, are the olive, the date palm, figs, grapes, and specialties, such as sugar-beets, cantaloupes and winter-grown vegetables. An attractive array of flowers, grown chiefly in the winter season and having commercial possibilities, includes roses, sweet peas, dahlias, and many flowering bulbs.

Various horticultural specialties are possible in Arizona at all seasons of the year. At higher altitudes apples are the most important horticultural crop. Among the most satisfactory varieties grown are Ben Davis, Arkansas Black, Gano, White Winter Pearmain, Jonathan, Limber Twig, and others. Excellent markets for the entire crop are to be found in the populous mining towns of the state; and consequently, practically no outside shipments are made. Peaches and pears are grown to the best advantage in irrigated valleys at higher altitudes, although they will also endure fairly well climatic conditions as low as Yuma. The Elberta peach is probably the best all-round variety for Arizona, although Late Crawford, Salway, Sylphide Cling, and others, do well. Among pears, the Kieffer produces fruit of comparatively fair quality for this variety; while Le Conte, Bartlett, Winter Nelis, and others, may be grown. A great advantage of the Kieffer is its resistance to blight, which badly affects other varieties in the region. Peaches and pears are also locally consumed, not yet being produced in sufficient quantity for outside shipments. Grapes produce abundantly in all sections, American varieties being grown at higher altitudes, while European varieties do best in the lower and warmer irrigated valleys. Raisins may also be manufactured from suitable varieties of grapes in those parts of Arizona sufficiently free from summer rains to permit of outdoor drying. Oranges, including Washington Navel, Valencia, Ruby, St. Michaels, Jaffa, and Mediterranean Sweet, can be grown at higher levels, in irrigated valleys up to 1,200 feet altitude in southern Arizona. Pomelos, including Marsh Seedless, Triumph, Duncan, and Aurantian, produce fruit of superior appearance and good quality. Lemons are profitably grown in the least frosty parts of the citrous districts.

Citrous fruits ripen in Arizona well in advance of the California crop, and as yet, fortunately, the orchards are entirely free from the pernicious scale insects which infest the orchards of California and Florida. These advantages, together with abundant and dependable water-supplies developed by the United States Reclamation Service and other projects in southern Arizona, give the citrous fruit-grower of the region special advantages in supplying eastern markets. Development of the citrous industry is therefore taking place rapidly, and probably will soon be the most important horticultural industry in Arizona.

The olive, which comes from semi-arid parts of the Old World, is at home in the lower irrigated valleys of Arizona. The trees grow vigorously with moderate water-supplies and are entirely free from the black scale which so disfigures the orchards of southern California. The quality of fruit produced is high, and the development of the oil and pickling industries is rapidly taking place at this time. The varieties best suited for pickles are Mission, Manzanillo, Sevillano; those best suited for oil are Mission, Correggiola, Nevadillo, Razza, Pendulina, and others. On account of its drought-resistance, the olive will undoubtedly be developed in parts of southern Arizona not having sufficient water for the more intensively cultivated crops.

The date palm is a very interesting and promising crop for altitudes up to 2,500 feet. In parts of northwest Mexico, resembling southern Arizona in climate, date palms up to 200 years of age, producing heavy crops, indicate a successful outcome for the many trees that are now being planted in southern Arizona. The selection of varieties of dates is exceedingly important because of the great difference in quality, productiveness and time of ripening of the different varieties. Although conditions in southern Arizona generally resemble those in date-growing regions of the Old World, they are sufficiently different in detail to reopen the whole question of the particular sorts best suited to Arizona conditions. At Tempe, 124 varieties of Old World dates have been under trial for fifteen years to determine the types best suited to Arizona conditions. Among the varieties at present approved for Arizona are Hayany, Khadvawi, Kustawi, Maktum, Moltagi, Nazl el Bacha, and possibly Deglet Noor,—the ideal being an early semi-dry cane-sugar date of high quality, ripening on the bunch, as far as possible, at one time.

The palm has many enemies, including rats and gophers, which may be controlled by poison and explosives; and date palm scales from the Old World, which multiply enormously under southwestern conditions. These, however, can be controlled by the blast-torch treatment, and by carbolic sprays. The fruit is damaged by untimely rains, by fruit-eating beetles, and by a spot-fungous disease which thrives in damp weather. To some extent these difficulties may all be overcome by artificial ripening processes, by means of which the mature but not yet soft fruits may be removed in bunches from the trees and artificially ripened by chemical or thermal treatments which hasten the maturing process, in rooms protected from insect pests or weather. Pasteurization of the finished product also kills the maggots and insect eggs which would otherwise in a short time ruin the product.

Many varieties of Adriatic figs are grown at altitudes up to 3,000 feet. Climatic conditions, especially along the Colorado River, are also favorable to the culture and handling of Smyrna figs, which, however, have not yet been developed because of the time required to establish Capri figs suitable for the maintenance of the Blastophaga wasp. Smyrna figs, however, should in time become an important horticultural asset of the region.

Heavy yields of cantaloupes of high quality are of frequent occurrence. Six cantaloupe-growers' associations have been organized in Arizona at different times, and the annual shipments are probably not far from 400,000 crates of melons.

Sugar-beets have been grown as a winter and spring crop, being planted in southern Arizona from December to February and harvested mostly during June and July.

Winter onions produce abundantly, crops of 20,000 pounds an acre of White Bermudas being recorded.

Strawberries produce from February to November in southern Arizona, the Arizona Everbearing being a productive variety originating in the region.

Beginnings are being made in various horticultural industries, such as the manufacture of olive oil and pickles, tomato canning, and the like.

On account of the newness of the region, the nursery business is only in its beginning, the larger part of nursery stock and seeds being imported from other states. Citrous stock for home trade, however, will soon be produced exclusively in Arizona, largely on account of the quarantine regulations established under the Crop Pest Law. The two largest nurseries in the state are located near Phoenix and Safford, respectively, and serve the Salt and Gila River valleys, in which they are located. The opportunity for developing varieties especially adapted to the region is exceptional, experience having shown in other new districts, especially in California, that the best varieties for a region are finally found to be those which originate there.

Public-service agencies for horticulture.

The Land-Grant school of Arizona is situated at Tucson. It was legally established in 1885, but operations did not begin until 1891. There are but two members of the horticultural staff.

The Experiment Station is also located at Tucson, although the cultural work is distributed through the state as follows: gardens and greenhouses at Tucson; experimental farm near Phoenix; date orchards and intensive gardens at Tempe and Yuma; dry farms at Cochise, Prescott and Snowflake. The staff consists of nineteen scientific workers. The number of horticultural bulletins and timely hints for farmers is approximately thirty-three.

The inspection of nurseries and orchards is in charge of the Horticultural Commission, a board of three members.

High-school courses to include the teaching of horticulture and agriculture have been endowed by the first state legislature of Arizona. All high-schools providing facilities for agricultural instruction are entitled to receive to the amount of $2,500 a year. Under the stimulus of this endowment, nine high-schools have installed these courses of instruction.

Associations exist for the marketing of oranges in Salt River Valley, of apples in the Verde and Gila valleys, and of miscellaneous produce in the Yuma and Gila River valleys. For the advantageous marketing of crops, association is necessary in a region somewhat distant from markets, and the movement toward association in connection with all horticultural industries in Arizona is strong.

Statistics (*Thirteenth Census*).

The land area of Arizona is 72,838,400 acres, of which 1.7 per cent, or 1,246,613 acres, is in farms. Of this land in farms, 28.1 per cent, or 350,173 acres, are improved; 100,061 are woodland; and 796,379 unimproved. [The total area is 113,956 square miles.]

The leading agricultural crops are hay and forage and cereals. The hay and forage occupied 102,490 acres in 1909 compared to 92,674 acres in 1899, an increase of 10.6 per cent. The value of hay and forage in 1909 was $2,553,228. The acreage in cereals in 1909 was 75,269; in 1899, 53,958, showing an increase of 39.5 per cent in acreage. The value of cereals in 1909 was $1,570,853. The value of the forest products in 1909 was $45,312; in 1899, $48,877. The value of sugar crops in 1909 was $251,602. The acreage in sugar crops increased 2,656.8 per cent in the past decade, from 183 acres in 1899 to 5,045 acres in 1909.

The leading horticultural crops and their value in 1909 were as follows: potatoes $126,695; other vegetables $379,293; fruits and nuts, $334,598; flowers and plants and nursery products, $15,712; small-fruits, $12,987.

The production of all orchard fruits increased 35.8 per cent in quantity from 1899 to 1909. The value increased from $96,764 in 1899 to $241,110 in 1909. Apples and peaches and nectarines lead in quantity of production and value. The number of bearing apple trees in 1909 was 62,027; of trees not of bearing age 53,884. The production in 1909 was 72,814 bushels valued at $109,395. The number of trees of bearing age in the case of peaches and nectarines was, in 1910, 51,415; those not of bearing age 32,562. The production was 50,102 bushels valued at $80,325. The production and value of the other orchard fruits in 1909 were as follows: pears, 13,289 bushels, valued at $21,331; plums and prunes, 8,420 bushels, valued at $16,261; apricots, 6,849 bushels, valued at $10,053; quinces, 1,815 bushels, valued at $2,805; cherries, 476 bushels, valued at $840.

There were 131,579 vines of grapes of bearing age in 1910 and 84,510 not of bearing age. The production in 1909 was 837,842 pounds and its value $25,371.

The principal nuts grown in Arizona are the almonds and pecans. In 1910, the almond trees of bearing age numbered 6,639; those not of bearing age, 845. The production of almonds in 1909 was 33,759 pounds, and their value $4,193. There were, in 1910, 64 pecan trees of bearing age and 212 trees not of bearing age. The production in 1909 was 1,075 pounds, and value $131.

The number of tropical fruit-trees of bearing age in 1910 were 51,036. They included, 818 pomelos (grapefruit); 1,216 date trees; 776 pomegranates; 9,353 olives; 33,373 oranges; 3,848 figs; and 1,652 lemons. The production and value in 1909 were as follows: pomelos, 820 boxes, valued at $1,508; dates, 6,500 pounds, valued at $96; pomegranates, 23,360 pounds, valued at $477; 264,895 pounds of olives, valued at $3,073; 32,247 boxes of oranges, valued at $52,341; 127,081 pounds of figs, valued at $4,103; and 1,010 boxes of lemons, valued at $2,034.

The total production of all small-fruits in Arizona in 1909 was 112,190 quarts, and in 1899, 129,000 quarts, and their value was $12,987 in 1909, as compared with $12,265 in 1899. The most important of the small-fruits grown in 1909 were strawberries, there being 58 acres devoted to the crop, producing 95,247 quarts, valued at $10,775. The production of blackberries was 13,808 quarts, amounting in value to $1,761. The other small-fruits were raspberries, loganberries, currants and gooseberries.

The leading vegetables were potatoes, sweet potatoes and yams, onions, tomatoes and watermelons. In 1909, from 1,151 acres of potatoes, there were produced 97,141 bushels, valued at $98,597. The acreage of sweet potatoes and yams in 1909 was 200, the production of which was 21,206 bushels, valued at $28,098. The production of onions in 1909 was valued at $11,480, and that of tomatoes $9,239. The value of watermelons from 735 acres, in 1909, was $52,502.

The area of land under glass, in 1909, used for the production of flowers and plants, was 29,810 square feet. Of these, 26,730 were covered by greenhouses and 3,080 by sashes and frames. The value of the products from flowers and plants was $11,177.

As regards nursery products, the value, in 1909, was $4,535, as compared with $2,914 in 1899. From 1899 the area devoted to the production of nursery products increased from 14 acres to 18 acres in 1909.

R. H. Forbes.

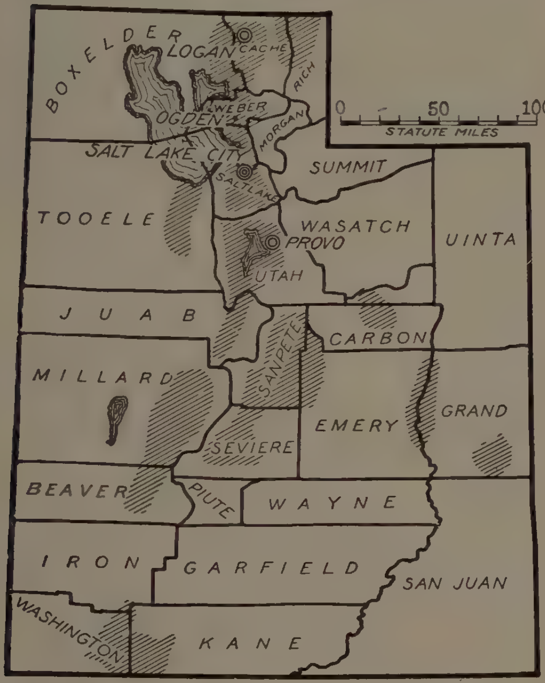
Utah.

The whole state of Utah (Fig. 2530) is cut up with mountain ranges running in a north and south direction. Between these mountain ranges lies the agricultural land of the state. These valleys vary in size from only 1 or 2 miles across, such as Pine Valley, to 30 or 40 miles in length by 8 to 15 miles in width, such as Cache Valley. The deep rich soil in these valleys makes a very intensive type of agriculture possible. The main fruit sections are at an altitude of 4,000 to 4,800 feet above sea-level. This includes the sections around Brigham, Ogden, Salt Lake, Green River, and Provo. At a higher altitude, frost-injury is likely to be experienced except in specially favored spots of limited area. Such small areas are usually at the mouths of cañons. The most desirable orchard sites are situated on the bench-lands and near cañons, thus insuring good air-drainage to ward off the occurrence of late spring frosts. Several extensive observations have been made which show that the average minimum temperature in the valley bottoms is from 8° to 10° F. lower than the bench-lands. The winter temperatures are congenial to apple-, pear,- peach-, plum- and sour cherry-production even in the northern part of the state, whereas apricots, sweet cherries and Persian walnuts thrive along the bench-land from Brigham southward. Almonds are being produced in the favored sections in the vicinity of Salt Lake City.

The average rainfall throughout the orchard sections of the state varies from 8 to 17 inches. With most of the rainfall coming during the dormant season, irrigation is necessary for practically all kinds of fruit-production in the state. The larger part of the orchards receive water from some of the irrigation canal systems. However, many acres of fruit have been developed about Brigham by pumping from wells. These wells vary in depth from 30 to 80 feet. Most of the pumps are operated by electricity which is obtainable at a very cheap rate.

Sagebrush (*Artemisia tridentata*) is the natural vegetation of the best orchard soils. Such soils are generally deep, rich and free from alkali. Greasewood (*Sarcobatus Baileyii*) and rabbit-brush (Bigelovia sp.) are found on soils containing more or less alkali, and perhaps otherwise unfit for fruit land.

The Mormons were the first to grow fruit in the intermountain region. With their first immigration to Utah in 1847, they brought seeds of grains, vegetables, fruit, shrubbery, trees, and vines. In a state thus settled by an agricultural people, fruit-growing became established early in its history, and held a place of importance in the agricultural development of the state. Practically every farm in the early days had its family orchard, consisting of many varieties of apples, peaches, plums, pears and cherries. Many of these trees were grown from seed. The following fruits which are gradually taking an important place in their respective classes originated in the state of Utah: the Poorman gooseberry, the Early Elberta peach, and the Knudson cherry. The planting of mixed orchards for local market purposes was well established as early as 1875. Bancroft, the historian, states that at this time there were from 500 to 600 acres of grapes in southern Utah, and the value of Utah's fruit products of all kinds was estimated at $157,000. The planting of commercial orchards for the general markets began about 1895 to 1900. This industry increased manyfold from 1900 to 1910.



2530. Utah, with important horticultural areas.

With the variations in altitude, soil, and exposure which exist within the state of Utah, it is possible to grow a great variety of fruits. Only the hardier apples, pears and small-fruits are grown successfully in the regions of high altitude, such as Summit and Rich counties, in the northern part of the state, where the altitude is 5,500 to 7,000 feet above sea-level. However, pomegranates, figs, and European grapes are grown to perfection in Washington County in the southwestern corner of the state at an altitude of 2,880 feet.

The chief fruit-growing sections are along the uplands at the foot of the west slope of the Wasatch Mountains from Brigham and vicinity to Provo and throughout the Bear River Valley. Cache County, at the north of the state, has a most favorable climate and soil for apple-production. Peaches and sour cherries are also a success here wherever suitable soil is obtainable. All except the most hardy sweet cherries, such as the Tartarian, are likely to suffer from late spring frosts in Cache County. Small fruit-growing areas have been developed recently in the vicinity of Price, Carbon County, and Green River, Emery County. Washington County is one of the oldest and it is naturally the most favored fruit section in the state. With a semi-tropical climate, this region excels in the production of the stone-fruits, European grapes, figs, pomegranates, almonds and Persian walnuts. Seclusion from railroad transportation has kept this country from developing a world-famous fruit-growing region.

Apples are the chief fruit crop of the state and make up more than half of the total acreage in orchards. With the exception of a few orchards planted for local markets, all commercial orchards are composed of late fall and winter varieties; chief among these are the Jonathan, Winesap, Rome, Ben Davis, Gano, Arkansas, Banana, and Rhode Island.

The peach orchards of Utah have been developed almost entirely to supply the fresh-fruit markets; therefore, the Elberta orchards compose nearly 90 per cent of the total acreage in peaches. Other varieties occasionally found are the Early Elberta, Early Crawford, Late Crawford, Lemon Cling, Tuscan, Champion, Alexander, and Hale's Early.

Cherries are the next most important fruit crop of the state, being produced chiefly around Brigham, Ogden, Salt Lake City and Provo. Most of this crop is sold in the fresh state among the markets of the intermountain region. A very firm high type of cherry is produced. Chief among the varieties are Napoleon, Tartarian, Hortense, Bing, Lambert, Windsor, Morello, Knudson, Double Natte, and Late Duke.

Small-fruits are produced for local markets and markets of the surrounding intermountain states. Strawberries, raspberries, dewberries, currants and gooseberries are readily produced practically throughout the state.

Pears, plums and apricots have been somewhat neglected in developing the fruit industry of the state, and although the nearby markets are partly supplied with Utah fruit of the above sorts, these fruits form a small part of the export trade of the state.

The grape, however, is the most neglected of all fruits in the state. The common American varieties can be successfully produced throughout the northern and central parts, and some of the most hardy European sorts, as the Thompson, can be produced from Box Elder County south to Washington County. Grapes are among the chief fruits in the latter county, where the following vinifera varieties are produced in abundance: Flame Tokay, Cornichon, Thompson's, Black Ferarra, and Muscat of Alexandria.

Utah apples, peaches, pears and cherries are packed almost entirely in boxes. The chief markets for this fruit are in the intermountain and plains states, where stock-raising and grain-production are the chief industries. The southern cotton states are also good markets for Utah fruit. Storage facilities have not been well developed as yet and oftentimes fruit is sold at a moderately low price by being rushed to an overstocked market.

Diversified fruit-growing is often encountered in Utah. Many orchardists grow several kinds of small-fruits as well as stone-fruits. Apples are often grown as one of the principal crops on a general farm. For example, the farmer may have 10 acres of apples, and 20 acres or more of such crops as sugar-beets, alfalfa, or vegetable crops for cannery purposes. With this system of farm management, the cost of production of the fruit crops is somewhat lower than on the more specialized fruit-farms, where the owner's time is not fully occupied throughout the year. Much of the general farm equipment can be used in the orchard, while the presence of live-stock on most of the fruit-farms goes a long way toward solving the question of maintaining soil fertility. Clean cultivation is practised in most of the bearing orchards, although some attention has been directed recently to the sod-mulch system of orchard management. The latter system seems to have considerable promise in the sections where irrigation water is not the limiting factor. While the young orchards are being grown to a bearing age they are usually intercropped with some vegetable or small-fruit crop, as sugar-beets, tomatoes, strawberries, and the like. Cover-crops are the exception rather than the rule, and the application of chemical fertilizers is practically unheard of within the state. Thus far the application of moderate amounts of stable-manure seems to have maintained the plant-food and humus.

Irrigation water is usually applied by the furrow system. The basin system is occasionally used, however, in the case of orchards growing a sod or a cover-crop. The number of irrigations necessary to produce a crop of fruit will vary considerably with the soil conditions and the kind of fruit. Apples on the clay-loam soils are usually watered three or four times during the season of July to September inclusive. Sufficient water is applied to wet the soil down to a depth of 6 or 8 feet.

Peach orchards and the other stone-fruits on gravel-loam soils with only a medium water-holding capacity, are more frequently irrigated than apple orchards, and less water is applied at an irrigation. For the best production of peaches, it is especially desirable to have plenty of water available during the season following the hardening of the pit till harvest time. No amount of water during the early growing season will make up for lack of water during the month preceding the harvest. Early irrigation stimulates vegetative growth and thus causes an even greater demand for moisture later in the season than would otherwise be the case.

The fruit industry of Utah has undergone little or no boom when compared with some other sections. The steady, conservative growth of this industry seems reasonably certain, and future generations may see the horticultural crops of more relative importance than they are at present.

Utah is characterized, as a whole, by farmers owning their own farms, and the fruit industry is no exception to this rule. Land values have remained at conservative levels. The fruit-grower not only owns the orchard in which he works but usually has no desire to sell it.

Truck-gardening has only been locally developed around Brigham, Odgen and Salt Lake City. However, the canning factories have developed profitable and intensive production of tomatoes and peas in various sections throughout the state.

The cut-flower establishments around Salt Lake City and Ogden supply the local markets and export a quantity of flowers to the northwestern states.

Utah is especially free from insects and plant diseases harmful to fruit crops. The arid climate makes an uncongenial home for most of the fungous diseases and only the easily controlled fruit insects are prevalent within the borders of the state.

Very stringent horticultural laws promote the production of clean high-class fruit, as it is a misdemeanor in the state of Utah to sell, ship or offer for sale any fruit infested with insect or plant-disease blemishes.

Utah fruit enjoys a very favorable reputation among local and general markets. Utah Jonathan apples, Napoleon cherries, and Elberta peaches bring the top prices for these varieties, and compare favorably with similar fruit from other fruit-growing sections, wherever comparisons are made. Rich soils, the intense sunshine of an arid climate, and an abundance of irrigation water combine to produce fruit of the very highest quality and color.

Public-service agencies for horticulture.

The Utah Agriculture College is located in the northern part of the state at Logan in Cache County. This institution was established in 1888. The horticultural staff consists of three teaching members.

The Agriculture Experiment Station, organized as a division of the College, has played an important part in helping the fruit-growers to solve their problems. The experimental staff has usually included at least one additional worker to the teaching staff mentioned above.

The following institutions in Utah teach one or more courses in fruit-growing to a large number of students of high-school and college grade: Utah Agriculture College Branch Normal School at Cedar City, Brigham Young University at Provo, Brigham Young College at Logan, Snow Academy at Ephraim, Murdock Academy at Beaver, and St. George Academy at St. George. With the exception of the first-mentioned, which is a state institution, the above schools were established and are now maintained by the Mormon Church. In addition to the above, every high-school in the state teaches at least one course in horticulture except schools located at Salt Lake City and Eureka.

The Utah Horticultural Society was formed in 1905 and has grown steadily in influence and value to the state since its foundation. A State Horticultural Commission was created in 1899, consisting of the Entomologist and Horticulturist of the Utah Agricultural College and three practical horticultural resident citizens of the state, one to be the Horticultural Inspector appointed by the Governor, and the other two to be appointed from the members of the State Horticultural Society.

Statistics (Thirteenth Census).

The approximate land area of Utah in 1910 was 52,597,760 acres. The land in farms was 6.5 per cent of the land area, or 3,397,699 acres. Of this land in farms, the improved land numbered 1,368,211 acres; the woodland, 145,510 acres; and other unimproved land in farms, 1,883,978 acres. The total number of all the farms in Utah in 1910 was 21,676, and the average acreage to the farm, 156.7. [The total area is 84,970 square miles.]

The leading agricultural crops grown in Utah are hay and forage, cereals, and sugar crops. The acreage devoted to the production of hay and forage increased from 388,043 in 1899 to 405,394 in 1909, when the production was valued at $7,429,901, which was 40.2 per cent of the total value of all crops. Cereals increased in acreage from 255,699 in 1899 to 298,613 in 1909, when the production was valued at $6,092,281, or 33 per cent of the total value of all crops. Sugar crops increased in acreage from 7,917 in 1899 to 27,812 in 1909, an increase of 251.3 per cent, when the production was valued at $1,871,478, or 10.1 per cent of the total value of all crops. Forest products of the farms were valued at 6,730 in 1909, as compared with $13,325 in 1899.

Horticultural crops grown in Utah are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $671,165, as compared with $291,902 in 1899. Small-fruits increased in acreage from 1,052 in 1899 to 1,416 in 1909, when the production was 3,118,395 quarts, valued at $217,327. The total acreage of potatoes and other vegetables in 1909 was 21,216 and their value $1,591,847. Excluding potatoes, other vegetables increased from 6,023 in 1899 to 7,006 in 1909, when the production was valued at $717,776. Flowers and plants and nursery products increased in acreage from 250 in 1899 to 597 in 1909, when the production was valued at $269,571.

The total production of orchard-fruits in 1909 was 633,739 bushels, valued at $640,904. Apples contributed more than one-half of this quantity, and peaches and nectarines ranked next in importance. The apple trees of bearing age in 1910 numbered 517,039; those not of bearing age, 789,260. The production in 1909 was 350,023 bushels, valued at $319,691. Peach and nectarine trees of bearing age in 1910 numbered 544,314; those not of bearing age, 651,233. The production in 1909 was 143,237 bushels, valued at $156,451. The production of the other orchard fruits in 1909 was: 68,249 bushels of plums and prunes, valued at $54,040; 21,402 bushels of cherries, valued at $54,170; 38,654 bushels of pears, valued at $44,365; 12,047 bushels of apricots, valued at $12,037; and 118 bushels of quinces, valued at $135.

The production of grapes in 1909 was 1,576,363 pounds, valued at $28,126. Grape-vines of bearing age in 1910 numbered 204,445 and those not of bearing age, 94,043.

The production of nuts in 1909 was 16,649 pounds, valued at $1,547. The nuts contributing to this quantity were 10,664 pounds of almonds, valued at $1,014, and 5,985 pounds of Persian or English walnuts, valued at $533. The production of tropical fruits was valued at $588, of which figs produced $576.

Strawberries are by far the most important of the small-fruits grown in Utah, with raspberries and loganberries ranking next. The acreage of strawberries increased from 345 in 1899 to 719 in 1909, when the production was 1,832,796 quarts, valued at $125,854. Raspberries and loganberries increased in acreage from 284 in 1899 to 374 in 1909, when the production was 758,317 quarts, valued at $54,826. Blackberries and dewberries increased in acreage from 72 in 1899 to 95 in 1909, when the production was 184,140 quarts, valued at $13,447. Currants decreased in acreage from 194 in 1899 to 128 in 1909, when the production was 195,901 quarts, valued at $13,435. Gooseberries decreased in acreage from 110 in 1899 to 100 in 1909, when the production was 147,241 quarts, valued at $9,765.

Potatoes, the most important of the vegetables, increased in acreage from 10,433 in 1899 to 14,210 in 1909, when the production was 2,409,093 bushels, valued at $873,961. Of the other vegetables grown, the more important were: 1,571 acres of tomatoes, valued at $154,455; 210 acres of cabbage, valued at $24,922; 323 acres of green peas, valued at $18,810; 192 acres of cantaloupes and muskmelons, valued at $16,917; 72 acres of onions, valued at $13,394; 137 acres of watermelons, valued at $12,232; 43 acres of celery, valued at $10,835; 99 acres of asparagus, valued at $10,645; and 120 acres of sweet corn, valued at $8,842. Vegetables of less importance were green beans, beets, carrots, cauliflower, pop-corn, cucumbers, squash and turnips.

The acreage devoted to the production of flowers and plants increased from 14 in 1899 to 20 in 1909. The total area under glass in 1909 was 261,292 square feet, of which 249,280 were covered by greenhouses, and 12,012 by sashes and frames. The flowers and plants produced in 1909 were valued at $81,116, as compared with $34,173 in 1899.

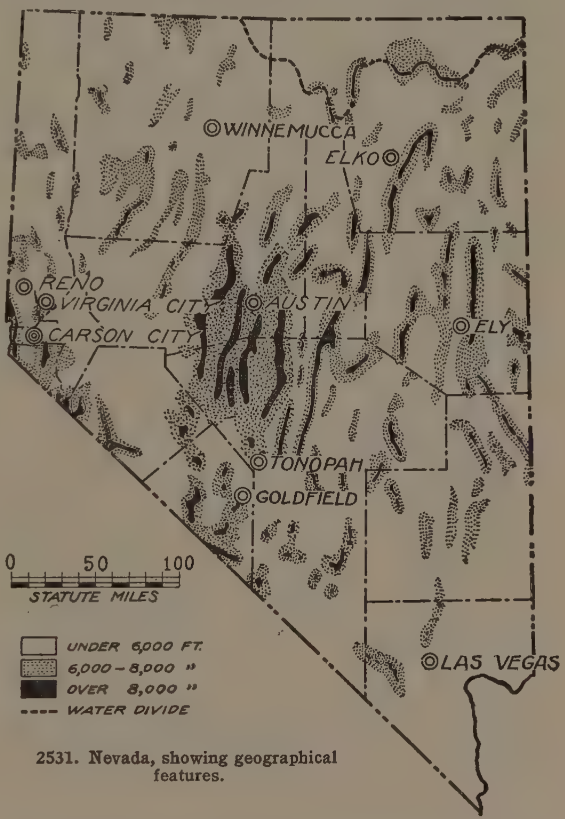
The acreage occupied by nursery products increased from 236 in 1899 to 577 in 1909, when the products were valued at $188,455, as compared with $120,648, in 1899.

L. D. Batchelor.

Nevada.

Nevada (Fig. 2531) comprises the western half of the Great Basin or plateau situated between the Rocky and Sierra Nevada mountain ranges. The general elevation of this plateau varies from 4,000 to 6,000 feet. Within the limits of Nevada there are numerous parallel mountain ranges sheltering approximately 200 valleys.

The climate is comparatively mild and semi-arid. The annual precipitation at the base of the main ranges varies from 10 to 26 inches in the west to 15 inches in the east and is as little as 3 inches in the interior valleys. In southern Nevada, the annual precipitation is 5 to 7 inches. On the mountain ranges the maximum winter precipitation in the form of snow reaches the water equivalent of 30 inches. Since two-thirds of the total annual precipitation occurs in the non-growing season, snow is the main dependence of the state for moisture on both range and farm, and is conserved by the mountains. Of these, the Sierra Nevada, Toyabe, Ruby, and Independence Ranges, three of which attain a maximum elevation of 11,400 to 14,500 feet, are the watersheds of the larger streams from which water for irrigation is derived. These streams, the Walker, Carson, Truckee, Reese, and Humboldt, traverse broad valleys and empty within the state. The Snake and the Colorado, on the northern and southern borders, are of little economic importance. The Muddy and its tributary, the Virgin, which flow into the Colorado, supply a limited area in southern Nevada.



2531. Nevada, showing geographical features.

The mean annual relative humidity is only 50 per cent. The rate of evaporation from water surfaces relative to other parts of the United States is high. Although strong winds occur frequently, destructive or blasting winds are rare. The mean annual velocity of the wind at Reno is 7 miles an hour.

According to temperature, which determines the length of the growing season and the type of products, Nevada is divided into three main divisions: northern and western Nevada, central Nevada, and southern or subtropical Nevada. The mean minimum temperature in northern Nevada ranges from 33.1° F. in the west (elevation 4,500 feet) to 30.2° F. in the east (elevation 6,000 feet); and the mean maximum temperature from 67.4° F. to 60.8° F. In central Nevada (elevation above 6,000 feet), the mean minimum temperature is 31.5° F. and the mean maximum 60.6° F., a condition too precarious for other than home horticulture. In southern Nevada (elevation below 3,000 feet), the mean minimum temperature is 48.9° F. and the mean maximum 81.9°.

An average of fifteen to twenty-five clear days and 74 to 89 per cent of sunshine occurs each month during the growing season. But intense radiation during the night diminishes somewhat the effect of the warm days. In northern Nevada, the growing season fluctuates from 77 to 168 days; in central Nevada from 52 to 139; and in southern Nevada from 130 to 240, the normal in each case lying midway between the two extremes. However, in the latter section the intense heat of the summer retards rather than accelerates growth.

The two great industries of the state are mining and agriculture, with a gross income for the former of approximately $35,000,000 and the latter of $15,000,000.

Irrigation is practised on approximately 90 per cent of the farms in Nevada, and little development of any source of water-supply other than streams has yet been made. Reservoirs still furnish only 5 per cent of the water used. The era of wells is just beginning. Dry-farming, which is necessarily limited to those parts of the state possessing a precipitation in excess of 12 to 15 inches, now embraces at least 4,000 acres.

Because of the preponderence of range land, forage crops have been greatly in excess of intensive crops and fruit, but seem now to have attained their highest acreage until the range is made capable of supporting a greater amount of live-stock, or until dairying and intensive stock-raising are established. The present (1915) value and relative importance of each is as follows:

Forage crops	$5,488,250
Cereals	1,838,400
Intensive crops	1,125,000
Fruit	200,000

On the basis of the forage crops, the intensive and fruit crops represent a value of 20 and 3.6 per cent respectively.

Except in the matter of frost, Nevada is ideally adapted for the growing of fruit; the clear skies and cool climate aid materially in producing fruit of fine external appearance and unusually delicate flavor. In northern Nevada, apples, plums, pears, and the hardier cherries are readily grown, while southern Nevada is congenial to the growing of peaches, pears, apricots, pomegranates, figs, olives, quinces, grapes, and almonds. The growing of citrous fruits is effectually prevented by the temperature of 20° F. that regularly occurs in the winter and by an occasional drop in temperature to 10° or even 9° F.

Seventy per cent of the orchard-fruits and grapes grown in Nevada are produced in three counties: Washoe, in 1910, producing 49.5 per cent; Nye, 12; Elko, 8.5. Lyon and Churchill counties are coming into prominence as potential producers of fruit. All of the standard varieties of apples are found in Nevada.

The frequency and duration of frost varies with elevation. According to a temperature survey of Washoe and Churchill counties, the temperature has been found to vary 8° in a rise of 13.5 feet and only 9.5° in 250 feet, the average variation being probably not more than half of these amounts. It has been found that an increase in elevation of 250 feet is accompanied by a decrease in the number of occurrences of frost of fourteen to five in a season and a decrease in the duration of freezing temperatures from at least forty to sixteen hours.

In the bottom lands of northern and western Nevada, the fruit crop fluctuates approximately as follows: full crop one year in five; total failure one year in five; and three half crops. In the foothills, only one total failure has been recorded in twenty-five seasons. At one point, 1,000 feet above the valley, apricot and almond trees, unknown to produce fruit elsewhere in northern and western Nevada, grow secure from frost. On the average, two heatings a season should save the Nevada crop, except in the coldest spots or in abnormal years.

The bench lands along the Sierra Nevada and the Ruby mountains compare closely in temperature with Provo, Utah, but are inferior to Grand Junction, Colorado. Furthermore, dry orcharding in these lands, as based on a five years' test, with an average annual precipitation of 13.61 inches, has proved successful, Ben Davis apples from the Elko County Dry Farm having received first prize at the State Fair in 1914.

The type of apple best adapted economically to Nevada is a late and long bloomer. Such is the so-called Nevada Sheepnose which has never been known to fail utterly. It is, moreover, a late keeper.

Most of the orchards and orchard land in Nevada are adjacent to railroads, but owing to the uncertainty regarding the crop, little effort is made to keep the orchards free from insect pests or to grade the fruit for marketing. Consequently, even the local markets are controlled largely by the California product. The orchards are usually small. Orchards of 20 to 50 acres are known, but these are very rare. The largest orchard is said to have 160 acres. Pears, plums, and cherries are grown only for family use.

In southern Nevada, apricots find a congenial environment because of the rainless weather at the time of ripening. Shipments of early fruit as well as the evaporated product find a ready market. For the same reason, and also because of a steadily increasing demand, almonds should be an ideal crop. Furthermore, the almond requires less moisture than most deciduous fruits.

The seedless grape industry is limited largely to acre tracts on each farm. One 50-acre vineyard is known. The grapes are shipped as raisins, but no attempt has been made to market them in carlots.

Of lesser fruits, the Mission and White Adriatic figs have been produced for years without a failure, and other varieties show especial promise. The Mission olives also "have withstood all extremes of temperature, and the few trees growing indicate possibilities of a new industry." Pears and quinces thrive in this climate, although the latter are not grown extensively. Peaches, especially the Elbertas, being short-lived, are grown only for home use.

In northern and western Nevada, raspberries, being late bloomers, are an unfailing crop. Currants and gooseberries are usually successful. Strawberries do well on the hill slopes. In southern Nevada, blackberries and dewberries are the most adaptable of the small-fruits; currants, gooseberries, raspberries, and strawberries are grown only with great care.

Owing to the scattered population and the control of the wholesale fruit industry by California companies, it will be difficult to increase the horticultural acreage unless concerted action is taken to develop the home as well as the foreign market. However, the impending increase in the dairy industry with resultant increase in population should stimulate the fruit industry; and since fruit requires, after the root system is developed, from 25 to 50 per cent less water than farm crops, it seems probable that fruit-culture on the higher slopes may become an independent industry, particularly so if combined with other intensive agriculture such as the raising of bees and poultry.

Of intensive crops, potatoes seem to be the coming premier crop in Nevada. Of the 840,000 acres of land now under actual cultivation, at least 150,000 acres are said to be adapted to potato-culture. The Inter-mountain States, because of their porous soils, moderate summer temperature, and control of moisture through irrigation, are well adapted to the raising of excellent potatoes, and Nevada especially so because of its proximity to the markets of California and the low shipping rates via the Panama Canal to New York. Under fair cultivation, five tons or 170 bushels of potatoes to the acre can be grown in Nevada, and under skilful cultivation the output can be increased to twelve tons. The average price is $20 a ton, the price fluctuating between $12 and $25. Early varieties adapted to the state are Early Ohio, Rose Seedling, and Early Rose; the late varieties, White Pearl, Rural New Yorker No. 2, Perfect Peachblow, Great Divide, Burbank, and Peerless. The greater part of the potatoes grown in Nevada come from three counties, Lyon, Washoe, and Elko, the ratio in 1910 being 25.9, 25.7, and 8.5 per cent respectively. In southern Nevada, only early marketing is profitable, for potatoes do not keep well in that climate.

It is probable that the area of potato land can be further increased by the use of dry-farming on the higher slopes of the mountain valleys, where the conditions of rainfall and frost are much more favorable than in the center of the valleys below. The rainfall should be at least 12 inches and preferably 15 to 18 inches, and the slope free from frost after the first of May. The only serious pest is the eelworm, a nematode gallworm, which causes some trouble. This parasite can be partially controlled by planting clean seed and rotating cereal crops with potatoes. Fall plowing and exposure of the soil to the hot sun has been suggested as a feasible method in Nevada where the winter cold is not sufficiently prolonged to destroy the eggs and larvæ.

The culture of onions is highly profitable if they are planted on the best soil, for the dryness and low temperature "make it comparatively easy to keep well-matured bulbs in inexpensive storage-houses until the market becomes favorable, which usually occurs after January 1, when the bulk of the California crop has been marketed." The best fields yield twenty tons an acre, and the normal price is $20 a ton.

The soil of western Nevada is well adapted to the growing of sugar-beets, which attain a general average of 18 per cent sugar. A beet-sugar factory at Fallon (Churchill County) on the Truckee-Carson Project has a capacity of 65,000 tons per annum, but tariff conditions and the difficulty of establishing a local market for beet-sugar have so far seriously retarded the industry.

Since watermelons and cantaloupes are perishable, their commercial cultivation is dependent upon the quality of the product placed on the market. In northern Nevada, they mature late and consequently must come into direct competition with the produce of northern California. In southern Nevada, the cantaloupe is well adapted to the climate and is matured by the middle of July, after the season in Imperial Valley is over and before the season in Utah and Colorado has begun. Consequently, there is a potential market on either side. At present cantaloupes constitute the chief crop of Moapa Valley (Clark County) and vicinity. In 1913, $80,000 or $160 an acre was realized from their sale after transportation charges and commissions were paid. In 1914 the crop was 75 per cent larger, but owing to unfortunate markets the profits were less. The most serious drawback is the melon aphis which is difficult to control. The varieties of watermelons are Kleckley Sweets, Halbert Honey, and Florida Favorite, and of cantaloupes Emerald Gem, New Fordhook, and Rocky Ford.

Celery is still an experimental crop, and in northern and western Nevada, skill is necessary to carry it through the warm summer. The celery is of excellent texture and good flavor, and the crop, although limited, is so valuable that it is shipped even into California, where it sells at a higher price than the local product. Since much labor and care are required in securing a good product, there seems little prospect of over-production.

Asparagus thrives in both northern and southern Nevada and will grow in soils too alkaline for most other crops. Furthermore, little summer irrigation is required. In southern Nevada, it is a poor second to cantaloupes as a commercial crop. It is marketed for six weeks in March and April in Chicago and other eastern cities. A canning factory is essential to care for the output after distant shipments are unprofitable.

The market and home gardens produce practically all of the vegetables grown in temperate climates, particularly beans, beets, cabbage, cauliflower, carrots, corn, cucumbers, garlic, kohlrabi, lettuce, onions, peas, pumpkins, radishes, squashes, sweet potatoes, rutabagas, tomatoes, and turnips. In southern Nevada, tomatoes ripen from late May until late November or December, the crop, however, being very light during the heat of summer. Commercial gardening in western Nevada is mainly in the hands of Italians, and the prices are reasonable. Except in southern Nevada, the market is local and is forced to compete to a certain extent with California. The winter-grown vegetables of southern Nevada find a parcel-post market in Salt Lake City. Lettuce has been shipped in carload lots, but the marketing of it has not always been successful.

Practically all the flowers and shrubs that are grown in the northern part of the United States, as well as the hardy perennials of California, grow well in northern Nevada. Peonies and bulbous plants bloom with only occasional injury from frost, and, owing to the lateness of the Nevada season, would find a ready market in California, if grown commercially. Owing to the dryness of the atmosphere, English holly does not thrive in this climate.

In southern Nevada, such semi-tropical plants as the oleander, the ornamental date palm, and weeping fan palm have been grown successfully. The bamboo and the pampas grass, which find a congenial environment in northern Nevada also, here grow to stately proportions, while the chrysanthemum supplies almost perfect blooms in the garden until after Thanksgiving.

Commercial greenhouse floriculture should be eminently successful, for the percentage of sunshine in the winter in Nevada is far in excess of that in California, and flowers can be grown in one-half the time.

Public-service agencies for horticulture.

The Agricultural College is situated at Reno and was established in 1888. It is an integral part of the University of Nevada. There is one member on the horticultural staff.

The Experiment Station is also at Reno and is a department of the University. The University and the Experiment Station possess two orchards, one exposed to frequent frosts, the other reasonably free from them. Two horticultural bulletins have been published, one on ornamental trees and shrubs, the other on the avoidance and prevention of frost.

A limited amount of extension work in horticulture is given. The Public Service Department of the University maintains an inspection service for plant insects and diseases, but not for fruit-grading.

Statistics (*Thirteenth Census*).

The approximate land area of Nevada in 1910 was 70,285,440 acres. The land in farms numbered 2,714,757 acres, or 3.9 per cent of the land area. The amount of improved land in farms was 752,117 acres; the amount of woodland in farms, 48,209 acres; and there were 1,914,431 acres of other unimproved land in farms. The number of all farms was 2,689 and the average acreage to the farm 1,009.6. [The total area of the state is 110,690 square miles.]

The leading agricultural crops of the state are hay and forage, and cereals. In 1909 the acreage devoted to hay and forage was 350,538, an increase of 20 per cent in acreage since 1899. The value of the production in 1909 was $4,185,071, which was 70.7 per cent of the total value of all the crops. The acreage in cereals in 1909 was 34,958, as compared with 31,075 in 1899; the production in 1909 was valued at $923,763, or 15.6 per cent of the total value of all crops. The value of the forest products of the farms in 1909 was $42,748, as compared with $23,853 in 1899.

Horticultural crops grown in Nevada are fruits and nuts, small-fruits, vegetables, including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $97,128, as compared with $16,752 in 1899, an increase in value of 479.8 per cent. Small-fruits decreased in acreage from 53 in 1899 to 37 in 1909, when the production was 50,287 quarts, valued at $5,683. The total acreage of potatoes and other vegetables in 1909 was 6,822, as compared with 3,164 in 1899; the production in 1909 was valued at $661,803. Vegetables, not including potatoes, increased in acreage from 924 in 1899 to 1,952 in 1909, when their products were valued at $264,122. In 1909, 1 acre was devoted to flowers and plants and nursery products, as compared with 5 acres in 1899, and the value of the production in 1909 was $2,113.

The production of all orchard-fruits in 1909 was 86,576 bushels, valued at $82,695. This production was nearly six times as great as in 1899, when 15,287 bushels were produced. Apples are by far the most important orchard fruit, producing nearly seven-eighths of the total production in 1909, when 74,449 bushels of apples were produced, valued at $66,097. The number of apple trees of bearing age in 1910 numbered 74,454; those not of bearing age, 16,868. The other orchard-fruits of any importance in 1909 were: 4,083 bushels of pears, valued at $5,119; 3,857 bushels of plums and prunes, valued at $4,654; 3,171 bushels of peaches and nectarines, valued at $4,500; and 524 bushels of apricots, valued at $1,418. In addition, cherries were produced to the value of $894, and quinces to the value of $13.

The production of grapes in 1909 amounted to 376,205 pounds, valued at $12,045, as compared with 287,600 pounds, the production in 1899. The number of vines of bearing age in 1910 numbered 26,607; those not of bearing age 7,941.

The production of nuts and tropical fruits in Nevada is relatively unimportant. In 1909, almonds were produced to the value of $606; Persian or English walnuts to the value of $20. Of the tropical fruits, in 1909, 45,550 pounds of pomegranates were produced, valued at $915; and 29,270 pounds of figs, valued at $818.

Of the small-fruits, the raspberries and loganberries are the most important, with gooseberries and strawberries next in importance. In 1909 the production of raspberries and loganberries was 17,841 quarts, valued at $1,901; that of gooseberries, 11,355 quarts, valued at $1,317; that of strawberries, 11,189 quarts, valued at $1,218; that of currants, 8,284 quarts, valued at $1,083; and 1,078 quarts of blackberries and dewberries, valued at $164.

The acreage devoted to the production of potatoes increased from 2,235 in 1899 to 4,864 in 1909, when the production was 766,826 bushels, valued at $396,652. Of the other vegetables grown in 1909 the more important were: 399 acres of cantaloupes and muskmelons, valued at $56,715; 124 acres of onions, valued at $32,523; 37 acres of lettuce, valued at $6,380; 43 acres of cabbage, valued at $5,467; 27 acres of asparagus, valued at $2,973; 34 acres of watermelons, valued at $2,923; and 10 acres of tomatoes, valued at $2,126. Vegetables of minor importance grown in 1909 were green beans, beets, carrots, cauliflower, celery, sweet corn, green peas, pumpkins, squash, and turnips.

There was 1 acre devoted to the production of flowers and plants in Nevada in 1909. The value of the flowers and plants produced from this 1 acre was $1,620. The total area under glass in 1909 was 4,600 square feet, all of which was covered by greenhouses. The land devoted to nursery products in 1909 was less than an acre, and their value $493.

J. E. Church, Jr.

PACIFIC STATES.

Washington.

The state of Washington (Fig. 2532) is naturally divided into two very different climatic areas. The slope on the west side of the Cascade Mountains is generally very rolling. The plains and mountain sections are usually covered with heavy timber. The elevation is from sea-level to 3,000 feet and mountain peaks extending to much greater elevations. The rainfall in the sections varies from 20 to 100 inches annually. The summers are generally warm and with very light rainfall. The winters are usually cloudy with a great deal of rain but with very little wind and cold weather.

The section of the state east of the Cascade Mountains is a broken elevated plain with mountains in the northern part of the state. The altitude varies from 500 to 3,600 feet, with mountains much higher. The rainfall varies from 5 inches in the lowest valleys to about 35 inches at elevations of 3,500 feet. There is practically no rainfall during the summer months and crop-production in the valley regions is developed almost entirely by irrigation. The temperature is equable and seldom reaches more than 16° below zero. The changes in temperature during the winter are usually gradual, and the extreme temperatures are seldom accompanied by wind.

The leading horticultural districts in the state are in the Yakima Valley, Wenatchee Valley, Spokane Valley, Okanogan Valley, and the lower Columbia Valley and the valleys of the Snake River. In the western part of the state the important horticultural districts are in Clark, Thurston, Pierce, King, and Whatcom counties.

Apple-growing is the leading horticultural industry in the state and in all probability will be for years to come. The fruit-growing sections producing apples in the largest quantities rank in the order named: Yakima Valley, Wenatchee Valley, Spokane Valley, Walla Walla district, Okanogan district, and the Clarkston district. The lower warm valleys grow the long-season apples, like Yellow Newtown and Esopus, to perfection, while the higher altitudes are best adapted to a shorter-season fruit, like the Wealthy and the Gravenstein. All apples color finely, and are very fair in appearance.

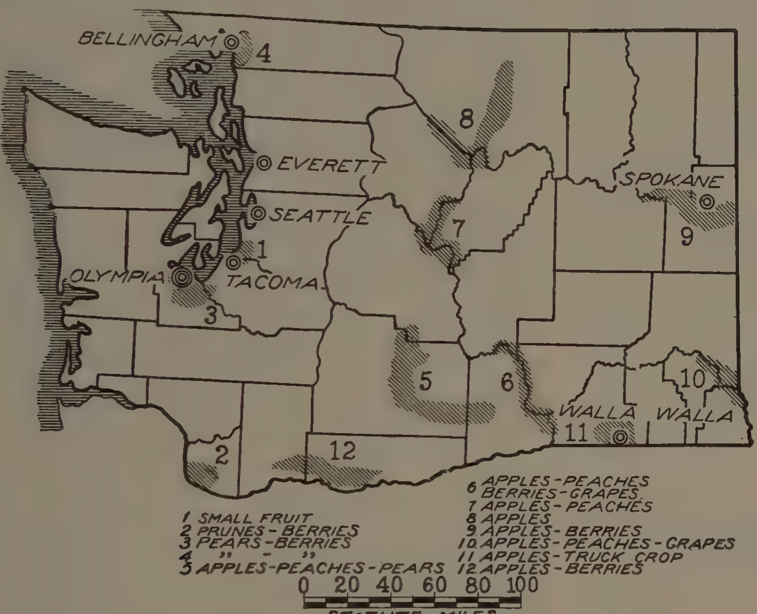
The greatest prune-growing area in the state is in Clark County. The Italian prune (Fellenberg plum) is planted in great numbers on both sides of the state. The French prune (Agen, Prune d'Agen, Petite, and the like), is planted in considerable numbers, but nothing like the Italian. Washington seems to be unable to compete with California in the production of this fruit. Nevertheless it is fairly profitable in Washington, yielding about the same number of pounds to the tree as the Italian, and selling in the eastern markets at a good price. But the Italian usually sells for more money, as the fruit is much larger. The Silver prune, or Coe plum (Coe Golden Drop), is a large, handsome prune when well prepared and always brings a good market price, selling for 2 or 3 cents a pound more than Italian or French. Not a great many are planted, and in some cases the prune-growers work their Silver prunes over to Italians. There are numerous varieties of prunes planted on the coast, but none in so great quantities as the Italian. Much of the fruit of this prune is shipped green, i. e., in a half-ripe condition. This finds its way to the most eastern markets, and some of it even to England. The fruit of the Italian stands shipment better than any other variety. Most large growers have evaporators in their orchards, and the most of the fruit is preserved in this way.

Pears are grown to great perfection in almost every part of the state, but there is no finer fruit than that which comes from the low warm valleys of the Snake, the Columbia, Walla Walla, and Yakima. The Bartlett is the great summer pear, followed closely by Flemish Beauty. For fall and winter, Anjou, Clairgeau, Easter and Winter Nelis are largely grown.

In peach-growing, the Yakima Valley ranks first, with Wenatchee Valley second, and Clarkston third.

In the growing of grapes, the lower Yakima Valley and the Columbia River Valley in the central part of the state are taking the lead, with the Clarkston district a close second.

Sweet cherries grow to great perfection in all parts of the state, but especially so in the Puget Sound region and in the warm valleys of the east side. The sour varieties also grow and yield abundantly. Sweet cherries attain their greatest perfection in the warm valleys at an altitude not much above 1,000 feet. Sour varieties do best on the high lands, at an altitude of about 2,000 feet. Cherries have been found to be profitable, yet few new plantations are being set. The reason for this is probably to be found in the labor market, it being almost impossible to get the necessary help to care for a large crop of cherries.



2532. Washington, with distribution of horticultural crops.

The greatest berry-growing section is in Thurston and King counties, Sumner and Puyallup being the centers. Bellingham, in Whatcom County, is the center of the berry and small-fruit district. Kennewick is the largest strawberry section east of the Cascade Mountains. Cranberry-growing is a new and rapidly developing industry in Pacific, Thurston, and Chehalis counties.

In the production of vegetables and truck crops the Walla Walla district ranks first, with Thurston and King counties second.

The vegetables that do well in cool weather are especially adaptable to wide planting in Washington and reach a very high measure of perfection. Lettuce, peas, onions, cabbage, cauliflower, kohlrabi, spinach, asparagus, and rhubarb do especially well. The warm-weather plants, such as tomatoes and sweet potatoes, are grown to the greatest perfection only in the lower altitudes. District above 1,500 to 1,600 feet are seldom able to mature tomatoes satisfactorily. The plant grows well and produces enormous crops of fruit in practically all sections of the state, but only the lower sections have sufficient length of growing season to make the crop profitable. Beans are grown in eastern Washington in great quantity. In the irrigated sections, this crop has not proved its capacity to adapt itself to the peculiar soil conditions existing. Celery can be grown in almost all sections of the state where the rainfall or water-supply is sufficient. There is a great deal of land in western Washington especially adaptable to this plant. Root crops, such as radishes, turnips, rutabagas, beets, carrots, and parsnips, do especially well. The plants of the crucifer family are very generally attacked by maggots and are difficult to grow to the highest degree of perfection unless planted extremely early or grown as an extremely late crop.

Seed-growing is a very important industry in Snohomish and Spokane counties. Large quantities of vegetable seed are grown in other districts also. The seeds grown in greatest quantity are garden and field peas, cabbage, cauliflower, beets, and turnips. Experimental work in bulb-growing is being conducted at Bellingham and promises to be the foundation for a large bulb industry.

Great progress is being made in Washington in the establishment of fruit-product plants. There are several canning factories being very successfully conducted. Several of these are on coöperative basis. They do a regular canning business in fruits and vegetables and find especially profitable the making of strawberry mash and the canning of cherries, pears, and tomatoes. There are several vinegar factories in the state that use only the cheap or culled grades of fruit. There is one commercial plant manufacturing the unfermented fruit juice, paying especial attention to grape juice.

The flowering plants ordinarily grown in gardens for commercial purposes do especially well in Washington. The rose probably does no better in any state in the Union than in Washington. Rose shows are very popular in the larger cities of the state. Sweet peas also reach a very high degree of perfection. Flower-culture, including the more common kinds for the home-garden, is receiving a great impetus, as it has been neglected greatly in the past. Commercial florists' work is developing rapidly. The most common plants handled are the carnations, roses, chrysanthemums, ferns, and foliage plants. The city trade is usually supplied by the local houses. A great deal of attention is being given now to the production of bedding and border plant materials. Greenhouse establishments are increasingly popular for the production of flowers, but very little is done along the line of forcing winter vegetables. Transportation rates from the southern part of California are such as to prevent profitable vegetable-forcing work. The lowland valley districts are capable of producing crops of lettuce as late as the latter part of November and also of placing the spring crops on the market from the out-of-door beds as early as March.

The nursery business has been well developed in this state, but has fallen off greatly in the last three years. At present the nurseries are developing good stocks of ornamental plants and trade is rapidly increasing.

The most common pests to the general horticultural crops are codling-moth, bud-moth, apple- and peach-tree borers, San José scale and the various forms of aphis. There are many other insects making trouble in small localities. Of the plant diseases, pear blight, apple-scab, apple powdery mildew, anthracnose, or black-spot canker, and brown-rot are the most common. There are a few physiological diseases that appear in the orchards. Most of these seem to be due to lack of adaptation of the plant to the peculiar soil conditions of the district. The most common spray materials in use are lime-sulfur, bordeaux mixture, nicotine sulfate and crude-oil emulsion.

The large orchard planting in Washington has been induced by the great profit made by the owners of the oldest orchards in the state. Between 1901 and 1911, many orchards yielded crops that netted their owners profits of several hundred dollars an acre. Heavy orchard planting followed. The extremely high price received for the apple before 1912 still left good profits after deducing high freight rates. The increased crop and reduced price has made the marketing problem a very difficult one. The organization of coöperative selling associations began about 1907, although some small organizations were in operation before that date. The coöperative canneries were among the first to start and the first to fail. The Puyallup-Sumner Fruit Association is one of the oldest and most successful organizations of its kind in the state. This organization owns and operates its own canning plant and handles approximately 95 per cent of the berry crop of that section. The organization is composed primarily of berry-growers. The Yakima Valley Fruit Growers' Association is a coöperative organization that sells fresh fruit only. This is the largest and one of the oldest local organizations in the state. There are now several similar organizations. The North Pacific Fruit Distributors is the largest coöperative organization in the state. It is composed of several affiliated local organizations. It is a selling agency only and does not attempt to do any of the work of the local organizations. Each local organization has its own brands and advertising methods and to a large extent its own set of rules for grading and packing. The f. o. b. sales at origin of the shipment are most desired by the grower, as the consignment shipments have very frequently failed to return a reasonable price to the grower.

Public-service agencies for horticulture.

The Land-Grant college of Washington is located at Pullman and was established in 1890. The institution is known as the State College of Washington. The Experiment Station is a department of the College and is located at the same place. At the present time there are seven men on the staff of the department, four doing college work only, and two connected only with the Experiment Station; the head of the department works in both College and Experiment Station. Since the establishment of the Experiment Station, fourteen bulletins have been published by the horticultural department. Several of these have been popular bulletins.

There are no special schools in this state teaching horticulture at the present time. Horticulture is taught in most of the high-schools in the state. Brief attention is given to it in the normal schools as a part of the agricultural course.

The extension work in horticulture is done by members of the Horticultural Department. Lectures, farmers' institutes, movable schools, and the conducting of correspondence courses in horticulture are the principal lines of activity.

The State Department of Agriculture has a subdivision of horticulture. The head of that division is known as Commissioner of Horticulture and all of the inspection work of the state is directly under his supervision. The state is divided into five inspection districts with district inspectors in charge.

The Washington State Horticultural Society is an organization of the fruit-growers of the entire state. Practically all of the members, however, reside east of the Cascade Mountains. The Western Washington Horticultural Society is an organization of the fruit-growers residing west of the Cascades. The special interest of this society is for the promotion of the fruit-growing industry in western Washington. Fruit-growing unions and commercial organizations exist in every fruit-growing section of the state.

Statistics (Thirteenth Census).

The approximate land area of Washington in 1910 was reported as 42,775,040 acres. The land in farms was 27.4 per cent of the land area, or 11,712,235 acres. Of this land in farms, the improved land numbers 6,373,311 acres; the woodland, 1,541,551 acres; and other unimproved land in farms, 3,797,373 acres. The number of all the farms in the state in 1910 was 56,192 and the average acreage to a farm 208.4. [The total area is 69,127 square miles.]

The leading agricultural crops of the state are cereals, and hay and forage. The acreage of cereals increased from 1,350,897 in 1899 to 2,591,582 in 1909, when the production was valued at $44,762,138, which was 56.7 per cent of the total value of all crops. Hay and forage increased in acreage from 497,139 in 1899 to 742,137 in 1909, when the production was valued at $17,147,648, or 21.7 per cent of the total value of all crops. The value of forest products of farms was $3,754,293 in 1909, as compared with $1,002,126 in 1899.

Horticultural crops produced in Washington are fruits and nuts, small-fruits, vegetables, including potatoes, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $4,329,058, as compared with $1,027,539 in 1899. Small-fruits increased in acreage from 2,845 in 1899 to 5,508 in 1909, when the production was 13,490,930 quarts, valued at $941,415. The total acreage of potatoes and other vegetables in 1909 was 82,312 and their value $5,982,665. Excluding potatoes, the acreage of other vegetables increased from 13,848 in 1899 to 24,410 in 1909, when the production was valued at $2,988,510. Flowers and plants and nursery products increased in acreage from 189 in 1899 to 1,682 in 1909, when the production was valued at $1,044,907.

The total quantity of orchard-fruits produced in 1909 was 4,244,670 bushels, valued at $4,274,124. Apples contributed considerably more than half of this quantity and plums and prunes most of the remainder. The apple trees of bearing age in 1910 numbered 3,009,337; those not of bearing age, 4,862,702. The production of apples in 1909 was 2,672,100 bushels, valued at $2,925,761. Plum and prune trees of bearing age in 1910 numbered 823,082; those not of bearing age, 122,912, and the production in 1909 was 1,032,077 bushels, valued at $600,503. Pear trees of bearing age in 1910 numbered 290,676; those not of bearing age, 617,754, and the production in 1909 was 310,804 bushels, valued at $328,895. Cherry trees of bearing age in 1910 numbered 241,038; those not of bearing age, 229,067, and the production in 1909 was 131,392 bushels, valued at $278,547. Peach and nectarine trees of bearing age in 1910 numbered 536,875; those not of bearing age, 1,028,141, and the production in 1909 was 84,494 bushels, valued at $118,918. Other orchard-fruits produced in 1909 were: 10,789 bushels of apricots, valued at $17,280; and 3,008 bushels of quinces, valued at $4,198.

The production of grapes in 1909 was 1,704,005 pounds, as compared with 1,194,700 pounds, the production in 1899. The value of the grapes produced in 1909 was $51,412. The number of vines of bearing age in 1910 was 322,007; those not of bearing age, 371,733.

The production of nuts in 1909 was 65,441 pounds, valued at $3,522. The more important of the nuts produced were: 16,450 pounds of English or Persian walnuts, valued at $2,241; 43,438 pounds of black walnuts, valued at $687; and 770 pounds of almonds, valued at $86.

Strawberries are by far the most important of the small-fruits produced in Washington, with raspberries and loganberries second in importance. The acreage of strawberries increased from 1,268 in 1899 to 3,283 in 1909, when the production was 7,683,774 quarts, valued at $529,535. Raspberries and loganberries increased in acreage from 625 in 1899 to 1,210 in 1909, when the production was 3,118,720 quarts, valued at $223,001. Blackberries and dewberries increased in acreage from 338 in 1899 to 769 in 1909, when the production was 2,340,779 quarts, valued at $159,094. Other small-fruits produced were: 194,365 quarts of currants, valued at $16,518; 143,264 quarts of gooseberries, valued at $12,285; and 9,728 quarts of cranberries, valued at $953.

Potatoes, the most important of the vegetables, increased from 25,119 acres in 1899 to 57,897 acres in 1909, when the production was 7,667,171 bushels, valued at $2,993,737. Of the other vegetables grown the more important were: 934 acres of cabbage, valued at $106,865; 415 acres of onions, valued at $67,949; 364 acres of tomatoes, valued at $62,613; 103 acres of celery, valued at $39,686; 561 acres of sweet corn, valued at $34,891; 352 acres of peas, valued at $27,758; 194 acres of asparagus, valued at $24,129; 310 acres of cantaloupes and muskmelons, valued at $18,688; 214 acres of watermelons, valued at $15,525; and 87 acres of turnips, valued at $11,484. Vegetables of less importance were green beans, beets, carrots, cauliflower, cucumbers, lettuce, parsnips, radishes, rhubarb, rutabagas, spinach, and squash.

The acreage devoted to the production of flowers and plants increased from 34 in 1899 to 340 in 1909. The area under glass in 1909 was 1,539,972 square feet, of which 1,257,616 were covered by greenhouses and 282,356 by sashes and frames. The value of the flowers and plants produced in 1909 was $518,226, as compared with $50,450 in 1899.

Nursery products increased from 155 in 1899 to 1,342 in 1909, when the value of the nursery products grown was $526,681, as compared with $28,699 in 1899.

O. M. Morris.

Oregon.

Oregon (Fig. 2533) is a state of great extremes, the rainfall varying from as high as 130 inches down to a very few inches, in extreme seasons certain sections averaging as low as 2 or 3 inches, although 9 or 10 inches is generally the minimum. Along the coast, the annual rainfall averages about 70 inches, while in western Oregon between the Cascade and the Coast Range mountains, the rainfall varies from 25 to 45 inches. East of the Cascade Range, it varies from 20 inches down to about 9 inches.

There is also an extreme range of elevations. This difference varies from sea-level to the frost line. This line, with the exception of a few favored locations, is in the neighborhood of 3,000 feet, and this elevation is about the limit of successful fruit- and tender vegetable-production in this state.

The soils in the horticultural valleys tend to vary greatly and are very spotted; nearly all extremes are found. It is not uncommon to find twelve or fifteen distinct types of soil in one small valley. These soils will vary from the heaviest adobe, or so-called sticky soils, to the lightest volcanic ash or pumice-stone soils.

These changes in rainfall, elevation and soils, coupled with certain climatic factors, such as length of growing seasons, mean temperatures, extremes of heat and cold, give the state a very wide range of conditions. This means that a great many varieties of fruit can be grown successfully. While it is true, however, that each locality may be able to grow only a few varieties to the highest degree of perfection, yet there are very few varieties of deciduous fruit that are not found within the state.

Oregon can geographically be divided into two districts,—western and eastern Oregon; the Cascade Range is the dividing line. Western Oregon, in turn, can be divided into two great districts, each of which can be further subdivided. The first great district extends between the Cascade and Coast Range Mountains and includes the Willamette, Umpqua, Rogue River, and other smaller valleys. The second district contains the area found west of the Coast Range Mountains and includes the coast counties of Coos, Lincoln, Tillamook, and so on.

East of the mountains several divisions can be made. First, there are those regions along the Columbia River and certain other parts of eastern Oregon which have a low altitude. These areas include such well-known districts as The Dalles, Hermiston and Freewater-Milton, which is a part of the Walla Walla Valley. Second, there are those regions which contain valleys of fairly high altitude, in the neighborhood of 2,000 feet, such as the Grand Ronde and certain areas in the vicinity of Vale and Ontario and a few of the interior valleys such as the John Day. The third district includes those regions found on the high tablelands. On the whole, this district is rather too bleak for successful commercial orcharding. There are, however, certain select parts along the streams and along certain of the lakes, like Summer and Goose lakes, that are splendidly adapted for fruit- and vegetable-production.

Hidden among the Cascade Mountains are found certain valleys which do not come in any of the classes already enumerated. These include such well-known regions as the Hood River and Mosier valleys.

In Oregon, fruit-growing is largely confined to valleys nestled among the mountains. Some of these valleys are very large; the Willamette Valley, for example, has 5,000,000 acres of tillable land. On the other hand many of the valleys are comparatively small, often containing only a few thousand acres.

The apple is the leading horticultural crop in Oregon and is being grown commercially in every horticultural section of the state. Within the last ten years, the planting of apples has gone forward on a tremendous scale and in the near future the output of this fruit should be enormous.

The prune is the second crop of horticultural importance in the state. East of the Cascade Mountains, it is grown in limited quantities for shipping green, while west of the mountains it is grown largely for evaporation purposes. The Italian (Fellenberg) prune is the principal variety grown, although a considerable quantity of French or Petite prunes are produced, especially in southern Oregon. There is an increased interest being shown in the prune within the last two years and new plantings have been very extensive.

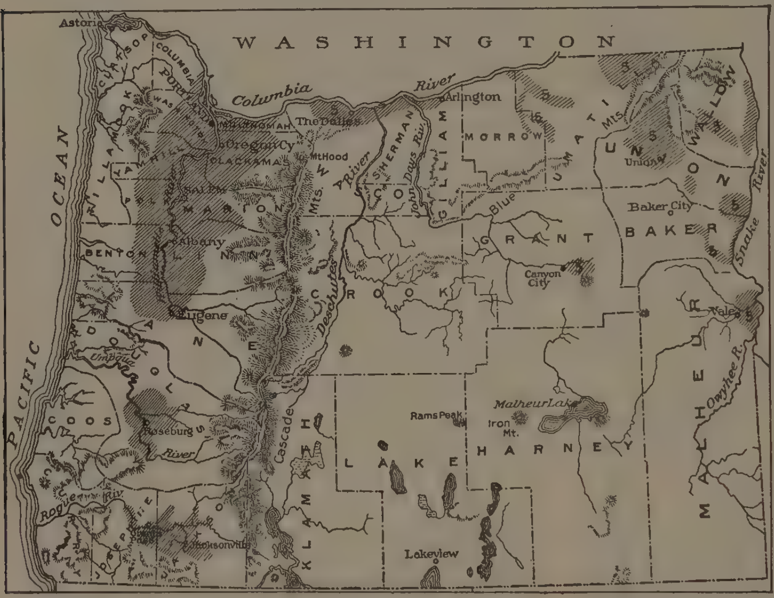
The pear is rapidly coming to the front commercially. In certain sections, very large areas have been planted and the tendency all over the state is to increase the acreage devoted to its culture. At the present time the pear-growing areas are confined to certain sections of western and southern Oregon.

Sweet cherries are grown very extensively in western Oregon. The Willamette Valley excels in cherry-production, the Lambert doing especially well in that section, although the Royal Anne and Bing are grown commercially. Along the Columbia River, in the vicinity of The Dalles, the Royal Anne (Napolean Bigarreau) does extremely well. In the higher altitudes of eastern Oregon, the Bing becomes the leading variety. Few sour cherries except those produced for home purposes are being grown at the present time. This fruit, however, does remarkably well in the state and there is some inclination toward commercial plantings.

Peaches are grown largely as fillers, there being but very few sections of the state as yet that have a distinct peach industry. The nearest approach to this condition is found at certain points along the Columbia, the Mission bottoms of the Willamette near Salem, and certain parts of the Rogue River Valley, especially at Merlin and Ashland.

In western Oregon, the principal developed horticultural regions are the Rogue River, the Umpqua, and the Willamette valleys. The Rogue River is rapidly becoming the pear center of the state. Large acreages of such varieties as Bartlett, Bosc, Winter Nelis, and Comice have been planted. In addition to the pear, extensive areas of apples, apricots and peaches are being grown. Grapes, especially of the vinifera type, such as the Tokay, Malaga and Muscat are receiving considerable attention.

The Umpqua Valley is rapidly developing into an apple district. Spitzenberg and Yellow Newtown are the leaders. Large areas of this valley, however, are devoted to the culture of French prunes, a few Italian prunes, and a scattered planting of almonds and English walnuts. The region is extremely early and some attention is being given to the production of early fruits and vegetables.



2533. Oregon, with the main horticultural parts.

The Willamette Valley, which is the largest horticultural valley in the state, is the center of the Italian prune, sweet cherry and the English walnut industry. In addition to these crops, large areas have been planted to both apples and pears. At the present time there is a revival of interest in the pear and a large acreage devoted to this fruit is being established. The loganberry output at the present time is largely centered in the Willamette Valley. The valley is so large and has so many varied conditions that its horticulture is becoming greatly diversified.

Along the coast, small-fruits grow to the highest degree of perfection and this is especially true of the brambles. The coast districts are also producing apples commercially, such varieties as the Gravenstein and King of Tompkins County growing particularly well. Coos Bay, from a horticultural point of view, is the leading section.

Along the Columbia River, in the heart of the Coast Range Mountains, is the Hood River Valley. This valley is unsurpassed in the grade of Spitzenberg and Yellow Newtown apples which it produces. There are other varieties which are being grown commercially and, of late, considerable attention has been given to pears, such varieties as the Anjou, Comice, and Bartlett all doing well. This section is also famous for its strawberry-production, the strawberry being the principal crop grown among the young trees. A few miles east of Hood River is a small section known as the Mosier Valley which has conditions similar to those found in Hood River.

The Dalles district which is along the Columbia River, 22 miles east of Hood River, is becoming famous for its stone-fruits, and vinifera grapes. Royal Anne cherries, apricots, peaches, plums and prunes, Tokay, Malaga and Muscat grapes grow to a wonderful degree of perfection. This section is also producing large quantities of vegetables, especially tomatoes for table use.

The Freewater-Milton district, which is a part of the Walla Walla Valley, is characterized by the diversity of crops which it produces. This region is very early and is attracting particular attention because of its ability to put early fruits and vegetables into our leading city markets. Nearly all the fruit from this district is shipped fresh.

The Grand Ronde Valley in eastern Oregon, in Union County, has one of the largest areas planted to apples to be found in the state. Such varieties as York Imperial, Rome Beauty, Gano and Jonathan are being planted very extensively. At Cove, in this same valley, prunes and cherries predominate. The Bing cherries from this district are famous because of their splendid shipping qualities.

There are many other valleys in the state which are producing fruit, but as yet only in small quantities. Some of these districts, such as the Pine Valley, Eagle Valley, John Day Valley, and a few regions in the vicinity of Ontario and certain select parts in proximity to Summer and Goose lakes, will undoubtedly develop their horticultural possibilities very extensively in the near future.

Oregon is developing a very large nursery business. In fact, one of the largest nurseries in the United States, namely the Oregon Nursery Company, is located at Orenco. This nursery has 1,000 acres planted to nursery stock at Orenco besides plantings in other parts of Oregon. There are also a number of smaller nurseries located throughout the state. Most of these, however, are in western Oregon in close proximity to Portland.

Among the unusual crops which are being grown in the state should be mentioned the English holly. A large number of persons are planting out this tree commercially. The tree thrives especially well in the rolling foothill country of western Oregon.

The cranberry is produced in this state very successfully and in all the coast counties limited areas of cranberry land can be obtained. Up to the present time, all bogs established have proved themselves very productive and have shown great promise for the future.

The loganberry is rapidly becoming one of the leading horticultural crops and the indications are that within the next ten years it may surpass in output all the other horticultural crops in the state. West of the Cascade Mountains there are large areas adapted to this fruit. It is very productive and, having so many uses, is meeting with a brisk demand. It is canned for sauces and pies, evaporated, made into jellies and jams, and produces a most excellent beverage similar to grape-juice.

Broccoli-growing is beginning to attract a great deal of attention. This crop is very easily grown and can be harvested during the winter, and in the very near future large shipments will be sent out of the state. A large area of land along the Columbia River and in the coast counties, and certain districts west of the Cascades, are adapted for this crop.

The onion is becoming one of the leading vegetable-gardening crops and is confined to certain sections of western Oregon which contain what is known as the Beaverdam soils. Many carloads of onions are shipped out of the state annually.

Some attention is being given to ginseng-growing, although as yet this industry is still in its infancy.

Since Oregon has few large cities, park systems of great importance have not been developed. However, the smaller towns and cities are growing very rapidly and many of them are establishing splendid foundations for future development. There are farms of vast acreage, but very few private estates have been developed as country homes.

The first fruit brought into the Northwest was introduced by the Hudson Bay Company in 1824. A group of young men who were about to sail from England for Vancouver were attending a banquet, and the young women present saved the seed from the apples eaten on the occasion, and gave them to the young men to plant in the new country. These seeds were eventually planted and the resultant grove of trees produced the first apples grown on the Pacific coast. In 1847, Henderson Lewelling and William Meek brought across the prairies from Iowa several thousand grafted sprouts, a few trees and a large quantity of seed. With this stock they established the first nursery in the state at Milwaukee. Ralph C. Geer, in the same year, also brought seed from the East and planted it. All these men were closely associated with the horticultural development of the state and, together with Seth Lewelling, were instrumental in its inception.

Seth Lewelling produced some of our finest varieties of fruit. Among these are the Bing and Black Republican cherries, which were produced in the sixties, and the Golden prune produced in 1876. J. H. Lambert in 1896 presented the Oregon State Horticultural Society with the Lambert cherry. This variety is probably the finest cherry grown in America, and is rapidly becoming our leading shipping sort. A. I. Shippley for years was identified with the grape industry, and was responsible for the introduction of many varieties which are now being grown commercially. Mr. Pettyman introduced the Oregon cherry, which is now being grown on a commercial scale in various parts of the state. Cyrus Hoskins brought out the Hoskins, Vesta and Lake cherries. They are very good, and superior to many now grown in America, but, owing to the introduction of the Bing and Lambert, have not been planted extensively. The Major Francis cherry, one of our best early varieties, was introduced by G. W. Walling, of Portland.

Other varieties of fruit of commercial importance which have been introduced by Oregon are the Winter Bartlett pear, Willamette and Pacific prune, Early Charlotte peach, Vanderpool Red apple, Clark Seedling, Gold Dollar, Magoon and Oregon strawberries.

Public-service agencies for horticulture.

Under the Land-Grant Act of 1862, Oregon was granted 90,000 acres of land. There was no state college in Oregon in 1868. The Legislature that year provided for the location of the land received and gave the interest on funds derived from the sale of the land to the Corvallis College, a private institution in Benton County, which was then under the control of the Methodist Episcopal Church. In 1885, the church voluntarily relinquished its claim on the College, and the State assumed entire control of the institution, which then became known as the Oregon Agricultural College. There are at present fourteen members of the horticultural staff.

The Experiment Station is also located at Corvallis. There are fifteen men giving part or all of their time to horticultural research work. Two of these men are located at Talent, in southern Oregon, where 20 acres of land are being devoted to pear-production problems. In Hermiston, eastern Oregon, three men are studying fruit-production problems under irrigated conditions, 40 acres of land being used for these problems. One man is located at Hood River, Oregon, investigating special apple problems. Forty-three bulletins on horticultural subjects have been issued in addition to circulars.

The College is also paying considerable attention to extension work, one man devoting his entire time to extension work in pomology.

There are no other institutions in the state giving instruction in horticulture. There is one correspondence school known as The Pacific Horticultural Correspondence School located at Orenco. Considerable attention is being given in the state to work in school-gardens and children's club work in horticulture. Other than this, however, there is very little horticultural teaching done, with the exception that in a few high-schools courses have been introduced.

The Oregon State Horticultural Society is the leading society of its kind in the state. There is a special State Board of Horticulture consisting of five commissioners, the state being divided into five horticultural districts and one commissioner having charge of a district. In most of the counties will be found County Fruit Inspectors under the jurisdiction of a commissioner. The duties of the Board of Horticulture consist largely of police duties, enforcing horticultural laws on spraying, quarantine, and so on.

Statistics (Thirteenth Census).

The approximate land area of Oregon in 1910 was 61,188,480 acres. The land in farms was 11,685,110 acres, or 19.1 per cent of the land area. Of this land in farms, 4,274,803 acres were improved land; 2,237,826 acres were woodland, and 5,172,481 acres other unimproved land in farms. The number of all the farms in 1910 was 45,502, and the average acreage of each 256.8. [The total area is 96,699 square miles].

The leading agricultural crops of Oregon are cereals, hay and forage and hops. The acreage of cereals increased from 1,222,648 in 1899 to 1,242,300 in 1909, when the production was valued at $17,860,136, which was 36.4 per cent of the total value of all crops. Hay and forage increased in acreage from 731,823 in 1899 to 939,979 in 1909, when the production was valued at $15,225,957, which was 31 per cent of the total value of all crops. Hops increased in acreage from 15,433 in 1899 to 21,770 in 1909, when the production was valued at $2,838,860. The value of forest products of the farms in 1909 was $2,889,991, as compared with $1,300,724 in 1899.

Horticultural crops produced in Oregon are fruits and nuts, small-fruits, potatoes and other vegetables, and flowers and plants and nursery products. The value of the fruits and nuts produced in 1909 was $3,452,205, as compared with $1,071,129, in 1899. Small-fruits increased in acreage from 3,470 in 1899 to 5,122 in 1909, when the production was 9,348,490 quarts, valued at $641,194. The total acreage of potatoes and other vegetables increased from 46,407 in 1899 to 67,399 in 1909, when the value of the production was $4,548,523. Excluding potatoes, the acreage of other vegetables increased from 16,345 in 1899 to 23,129 in 1909, when the value of the production was $2,448,917. Flowers and plants and nursery products increased in acreage from 1,072 in 1899 to 2,298 in 1909, when the production was valued at $1,051,853.

The total production of orchard-fruits in 1909 was 4,423,244 bushels, an increase of 190.6 per cent over the production in 1899. Apples were the most important of the orchard-fruits, with plums and prunes second in importance. The number of apple trees of bearing age in 1910 was 2,029,913; those not of bearing age, 2,240,636, and the production in 1909 was 1,930,926 bushels, valued at $1,656,944. The plums and prune trees of bearing age in 1910 numbered 1,764,896; those not of bearing age, 427,609, and the production in 1909 was 1,747,587 bushels, valued at $838,783. Pear trees of bearing age in 1910 numbered 273,542; those not of bearing age, 795,669; and the production in 1909 was 374,622 bushels, valued at $366,977. Cherry trees of bearing age in 1910, numbered 223,456; those not of bearing age, 313,770; and the production in 1909 was 181,089 bushels, valued at $269,934. Peach and nectarine trees of bearing age in 1910 numbered 273,162; those not of bearing age, 508,179; and the production in 1909 was 179,030 bushels, valued at $194,314. Other orchard fruits produced were 4,616 bushels of apricots, valued at $7,727, and 5,354 bushels of quinces, valued at $5,140.

The production of grapes in 1909 was 3,206,874 pounds, valued at $98,776. The vines of bearing age in 1910 numbered 381,302; those not of bearing age 468,598.

The production of nuts in 1909 was 177,632 pounds, valued at $13,208. English or Persian walnuts are the most important nut, the production in 1909 being 79,060 pounds, valued at $8,288. The English walnut trees of bearing age in 1910 numbered 9,526; those not of bearing age, 177,004. Other nuts produced in 1909 were: 17,515 quarts of almonds, valued at $2,468; 69,097 pounds of black walnuts, valued at $1,333; and 5,731 pounds of chestnuts, valued at $599.

Of the small-fruits, strawberries are the most important in Oregon, with raspberries and loganberries ranking next. The acreage devoted to strawberries increased from 1,792 in 1899 to 2,941 in 1909, when the production was 5,322,040 quarts, valued at $395,349. Raspberries and loganberries increased in acreage from 479 in 1899 to 1,460 in 1909, when the production was 2,644,948 quarts, valued at $150,729. Blackberries and dewberries decreased in acreage from 717 in 1899 to 431 in 1909, when the production was 915,744 quarts, valued at $61,066. Other small-fruits produced were: 307,395 quarts of gooseberries, valued at $20,893; 117,354 quarts of currants, valued at $9,452; and 40,864 quarts of cranberries, valued at $3,527.

The acreage of potatoes increased from 30,035 in 1899 to 44,265 in 1909, when the production was 4,822,962 bushels, valued at $2,098,648. Of the other vegetables produced the more important were: 721 acres of onions, valued at $168,261; 591 acres of cabbage, valued at $65,296; 203 acres of tomatoes, valued at $39,060; 568 acres of watermelons, valued at $32,842; 198 acres of cucumbers, valued at $22,825; 457 acres of sweet corn, valued at $21,371; 113 acres of cantaloupes and muskmelons, valued at $14,337; 24 acres of celery, valued at $14.290; and 50 acres of horse-radish, valued at $13,570. Vegetables of less importance grown in Oregon in 1909, were asparagus, green beans, beets, carrots, cauliflower, pop-corn, lettuce, parsnips, rhubarb and squash. The whole range of temperate vegetables can be grown in the state.

The acreage devoted to the production of flowers and plants increased from 58 in 1899 to 130 in 1909. The total area under glass in 1909 was 716,543 square feet, of which 672,207 were covered by greenhouses, and 44,336 by sashes and frames. The value of the flowers and plants produced in 1909 was $268,833.

The acreage of nursery products increased from 1,014 in 1899 to 2,168 in 1909, when the value of the nursery products was $783,020, as compared with $151,498 in 1899.

C. I. Lewis.

California.

The horticultural resources of the state of California (Fig. 2534) can best be understood by a careful and thorough study of its geographical features, preferably by a contour map. Its more striking features consist of a rugged coast-line of a thousand miles on the ocean; a rugged, much-broken group of interlocked mountain chains, forming, as a whole, the great Coast Range, with its fertile valleys, plains, uplands, forests and pastures; a vast interior valley-plain, one of the richest in the world (the Sacramento and the San Joaquin valleys); the high Sierra Nevada Mountains along the northeast and east sloping down to the deserts, the Death Valley, and Salton Sink. This great region has marked unity and individuality, a multitude of local climates, much variety of soil and rainfall, and physical conditions which strongly differentiate it from the remainder of the United States. Its length north and south is 780 miles, and its width is from 150 to 350 miles. It is the second largest state in the Union, and the value of its staple horticultural products places it notably in the lead in these industries. New York, Ohio, Maine, New Jersey, Vermont, Massachusetts, New Hampshire, Connecticut, Delaware, and Rhode Island, united, have a less area than California.

The range of products grown in California is greater than that of all the remainder of the United States: the humid sea-level islands of Florida are adapted to some plants, such as cassava, which thrive but poorly in California, but on the sheltered uplands of California many species which entirely fail in Florida are perfectly at home.

In many places in California, a botanical garden might easily be established where a greater number of species of plants and trees would thrive than have yet been brought together anywhere else in outdoor culture. The United States Bureau of Plant Industry has now (1915) test-gardens in various places as far north as Chico, where many species of exotics are thriving. In ordinary cultivation in California one finds, and often on an enormous scale, the vines, walnuts and prunes of France; the olives, oranges, lemons, chestnuts, figs and pomegranates of Italy and Spain; the acacias, eucalypts, casuarinas and salt-bushes of Australia; the melons of Turkestan; the rice of China; the cotton and tobacco of the South; the hemp, flax, rye, Russian mulberries, and other products of the more extreme North, the cereals of the great West, the bulbs of Holland, the costly seed-crops of European gardens, and, in brief, examples of all the useful horticultural productions of the temperate zones, together with the greater part of the species of the semi-tropical and even some plants from the tropical regions. More than a hundred species of palms grow at Santa Barbara; many species of bamboo thrive at Bakersfield, and as far north as the base of Shasta. Eucalypts, acacias, camphor and cinnamon grow over the greater part of the state.

While the American pioneers of Kentucky were fighting the Indians and struggling to obtain the right to navigate the Mississippi, the Spanish pioneers of California were raising seedling peach, pear, lemon, orange and date-palm trees, were growing figs, grapes, and olives from cuttings brought from Mexico, and were making marvelous beginnings of horticulture about the early missions. After the American conquest, and the gold discovery of 1848, horticulture gained a foothold in the mountain lands below the Sierra peaks. Every village and town had its gardens and its beginnings of orchards. Soon the thoughts of men turned to the broad, fertile, untilled valleys, and in a few years the wheat farmer became the typical Californian.

LXXIV. North American horticulture.—Foothills orchards in California.

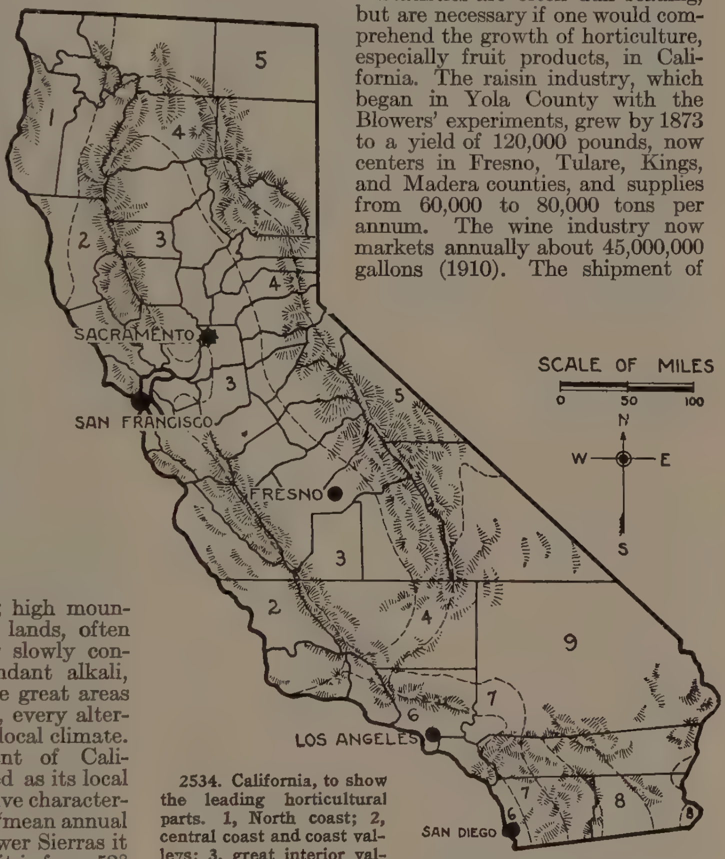
Lastly, the state entered upon a magnificant and still-continuing period of horticultural developments, which well deserves to be written down in history as one of the most important facts of modern material rogress.

Horticulture in California naturally divides itself into several distinct historical periods, such as: (1) The pre-American era, which ended with the gold discovery; (2) the pre-railroad period, when only California and to a small extent the Hawaiian Islands, the Orient and South America, were supplied with local products; (3) the period of expansion due to the opening of eastern and European markets by the railroad; (4) the modern period, since 1904, when the National Forest System, the conservation of water-supply, the rapid development of hydro-electric power all over the mountain regions of California, the extension of markets, rapid increase in population, and broader horticultural education, have united to establish every industry connected with plant life upon a more solid foundation.

Because of these recent developments in California, forests, pastures, farms, gardens, so suggestively occupy the land that, although there is room for many more, it is difficult to call anything horticulturally worthless except the great heights that shelter and water the valleys below. Even the deserts have underlying streams, and blossom with trees and vines as men sink artesian wells there; and on the unirrigated deserts the spineless cacti begin to create a new industry. The miracles of Italy, ancient Palestine, modern India, are being repeated over large districts of California.

The great valleys and nearly level lands of California, subject to frosts, comprise about 40,000,000 acres of land; the foothill fruit-belts, of Coast Range and Sierra, hardly as yet one-fifth occupied, comprise fully 25,000,000 acres; in timber and fine grazing land, capable of perpetual renewals, are 15,000,000 acres; high mountains cover some 10,000,000 acres; arid lands, often yielding enormously under irrigation, or slowly conquered by neutralizing their superabundant alkali, occupy about 8,000,000 acres. Over these great areas every wind current, every mountain spur, every alteration in slope or altitude, helps to make a local climate. The complicated geological development of California has produced soils almost as varied as its local climates. The state has been divided into five characteristic climate-zones: in the high Sierras the "mean annual temperature" is from 30° to 44°; in the lower Sierras it is from 44° to 52°; near the Pacific Ocean it is from 52° 67°; in the central valleys of Sacramento and San Joaquin it is from 60° to 68°, and in the southern counties from 68° to 72°. But every part of California shows very sharp horticultural contrasts upon farms not a mile apart. Local climate is the true keynote of California life. Placer County, for example, extends from the center of the Sacramento Valley east to the summit of the Sierras. It has upland Canadian valleys, pines and snow-blockades at one end; groves of oranges and lemons in the Sierra foothills, and rich alfalfa and rice fields along the "bottoms" of the Sacramento Valley rivers. Too much emphasis cannot be placed upon this local variation. For California no reliable horticultural map can yet be made. Citrous fruits, for example, are found to thrive wonderfully along the foothills of the Sacramento and the San Joaquin valleys, and far up in many a mountain valley. The most careful experimenting with each location, and indeed with all parts of each separate farm, are the keynotes of success in California. "Mean annual temperature" is a comparatively small factor in the California climate; winds, fogs, rainfall, frosts, and the daily variations of temperature are the all-important items.

It is now evident (1915) that the growth of citrous fruits, European grapes, olives, walnuts, chestnuts, and the finer deciduous fruits, will be leading industries over three-fourths of California; that large portions of the valleys of the Coast Range and some of the Sierra foothills will increasingly produce winter vegetables, small-fruits, the finer seeds, bulbs, cut-flowers, and the like; that the hotter, more arid districts will grow date palms, spineless cacti, the earliest melons, and many tropical fruits. In these respects Imperial Valley has been a revelation of immense possibilities.



2534. California, to show the leading horticultural parts. 1, North coast; 2, central coast and coast valleys; 3, great interior valleys and lower foothills; 4, higher foothills and mountains; 5, arid plateaus and mountains; 6, southern coast; 7, southern foothills; 8, irrigated desert areas; 9, southern desert.

Statistics are often dull reading, but are necessary if one would comprehend the growth of horticulture, especially fruit products, in California. The raisin industry, which began in Yola County with the Blowers' experiments, grew by 1873 to a yield of 120,000 pounds, now centers in Fresno, Tulare, Kings, and Madera counties, and supplies from 60,000 to 80,000 tons per annum. The wine industry now markets annually about 45,000,000 gallons (1910). The shipment of fresh deciduous fruits in 1911 above the supply of local demand, approximated 13,000 carloads; the shipments of cured fruits in 1911 were nearly 190,000 tons; the citrous fruit crop of that year was 14,000,000 boxes. The annual pack of canned fruits and vegetables is not less than 5,000,000 cases. Shipments of 1910 were 73,745 tons of canned fruits and vegetables and 78,829 tons of green vegetables, besides local consumption.

The growth of these interests can also be illustrated by the census reports on trees and vines. The first assessor's tabulations in 1850 showed a few dozen grape-vines, orange trees, and the like, about the old missions. In 1893, these reports showed that nearly half a million acres were in vineyards and orchards; seventeen years later (1910) the State Board of Equalization report of vines was as follows:

Class of fruit	Acreage bearing	Acreage non-bearing
Grape, table	35,859	17,970
Grape, raisin	108,882	19,385
Grape, wine	125,109	35,518
Total acreage of vines	269,850	72,873
Total of all vines	342,723 acres	

In 1914, the state had nearly 1,200,000 acres in orchards.

The five leading counties in their acreage of table grapes are San Joaquin, Fresno, Sacramento, Tulare and Placer. In raisin grapes, Fresno greatly leads, with Kings second, and Sutter third. Fresno, Napa and San Joaquin lead in wine grapes; Santa Cruz, Sonoma and Mendocino have the greatest number of apple trees; Santa Clara, Kings, Alameda and Ventura of apricots; Fresno, Kings, Placer and Santa Clara, of peaches; Fresno and Los Angeles of figs; Fresno and Placer of nectarines; Los Angeles, Riverside and Tehama of olives; Santa Clara, Sonoma and Placer, of plums and prunes; San Bernardina, Los Angeles, Riverside and Tulare of citrous fruits.

In recent years, the nursery business has been greatly extended, particularly in southern California, where the demand for rare plants and trees is constantly increasing.

Active clubs and associations of florists, gardeners, nurserymen, and amateurs interested in horticulture exist in various parts of California. In Ventura, Santa Barbara, the Lompoc Valley, Pasadena, Whittier, Santa Ana, Pomona, Riverside, and over a large area around Los Angeles, also in Santa Clara, Alameda, Marin, Sonoma, and other counties, many of the lesser horticultural industries are gaining strength year by year, as population increases.

The growth of parks, fine estates, and horticultural collections of note, while not as yet developing into a really great botanic garden, such as California should have, has still been noteworthy. The Golden Gate Park of San Francisco, the parks and public squares of Oakland, San Jose, Sacramento, Fresno, Los Angeles, Riverside, Pasadena, Redlands, San Diego, and many other cities, are becoming of much interest and importance. The beauty and, indeed, the splendor, of thousands of superb private estates around San Francisco, north, south, and on the east side of the Bay, in Santa Cruz and Monterey, and in southern California, have achieved a world-wide fame. Of especial importance are the Bidwell collections at Chico, the Gillespie arboretum at Montecito, Smiley Heights at Redlands, the Del Monte gardens near Monterey, the Stanford plantings at Palo Alto, the Tevis bamboos near Bakersfield, the collections of Dr. Pierce at Santa Ana, the government plant-gardens at Altadena, Chico, and other points, and the University of California stations at Berkeley and Santa Monica.

One of the most impressive facts connected with California horticulture is the extent to which state and national study of the problems involved has resulted in better methods and more complete organization. The citrous industry in particular has greatly profited from the investigations made by experts upon cultural methods, packing details, and so on. The University of California, the Experiment Station and institute work, have everywhere taught scientific methods and organization, until now (1912) the effectiveness of the fruit exchanges, and the general interest in the movement toward complete standardization of methods and products is everywhere increasing. One of the greatest factors in this progress is the State Horticultural Commission, formerly the State Board of Horticulture.

California has had many horticultural publications, large and small; some of them continue, and others enter the field every year. The Pacific Rural Press, although not horticultural in name, has presented the horticultural adaptabilities from its foundation in 1870, under the editorship of Professor Wickson. The official literature, state and national, and the mass of reports upon its horticultural industries which envoys from other countries have issued, is very large indeed.

The most striking single fact, however, in regard to California horticulture appears to be that since 1900 it has shown a marked tendency toward systematic organization and the most painstaking scientific study of its problems, to the end that as new horticultural centers develop, and older ones increase, each community will specialize according to its local resources. At the present time (1912) a committee of nurserymen are collecting and tabulating all available facts in regard to the percentage of trees which reach profitable bearing under different conditions, and in different localities. A similar spirit of investigation extends to all the minor horticultural industries, so numerous and so rapidly increasing in importance with a growing population. The planting of eucalpyts on a large and widely-advertised scale, has lessened, but still goes on. Acacias are being planted, to some extent, for tanbark, and bamboos for furniture.

The horticultural development of California has come in large measure from the tireless efforts of many and hard-working pioneers in every department. Nurserymen and gardeners like Fox, West, Rock, Lewelling, Sievers, spent their profits in experiments and introductions. Men and women like E. L. Beard, General John Bidwell and his wife, J. DeBarth Shorb, of San Gabriel, Mrs. Jeanne C. Carr, Mrs. Theodosia B. Shepherd, of Ventura, Mrs. M. E. Sherman, and many others, did noble pioneer work.

Public-service agencies for horticulture. (W. T. Clarke.)

The Land-Grant College is situated at Berkeley, and was established in 1868. The horticultural staff consists of thirty members. Aside from the usual equipment, the department has about 100 acres in the central and northern part of the state devoted to orchard purposes, and 200 acres devoted to the same purpose at the Riverside Citricultural Station.

The Experiment Station is also located at Berkeley, although the larger part of the work is done at the farm at Davis, the Kearney farm near Fresno and at the Riverside Station. A small amount of work is also done at the Imperial Valley Station, near Meloland. About 160 horticultural bulletins and 62 circulars have been issued.

Extension work in horticulture is given in connection with farmers' institutes, movable or extension schools and agricultural rural improvement clubs. An extensive correspondence is also carried on by the department.

Horticulture is taught in many of the public schools.

Statistics (*Thirteenth Census*).

The approximate land area of California comprises 99,617,280 acres, of which 27,931,444, or 28 per cent, are in farms. Of these 27,931,444 acres in farms, 11,389,894, or 40.8 per cent, are unimproved; 4,541,767 acres are in woodland; and 11,999,783 acres are unimproved. The total number of farms in the state is 88,197. The average acres to the farm are 316.7. [The total area of the state is 158,297 square miles.]

The leading agricultural crops are cereals, hay and forage, hops, sugar crops, and forest products. The cereals occupied 17.3 per cent of the improved land, or 1,970,492 acres, in 1909, a decrease in acreage of 50.8 per cent since 1899, when they occupied 4,004,254 acres. The value of the cereal products in 1909 was $28,039,826. Hay and forage occupied 22.2 per cent of the improved land area in 1909, or 2,533,347 acres, an increase in acreage of 13.1 per cent since 1899, when they occupied 2,239,601 acres. The value of hay and forage in 1909 was $42,187,215. The acreage of hops increased from

6,890 in 1899 to 8,391 in 1909, an increase of 21.8 per cent. The value of hop products in 1909 was $1,731,110. Sugar crops increased in acreage 92.4 per cent,—from an acreage of 41,382 in 1899 to 79,604 in 1909. The value of the sugar crops in 1909 was $4,335,358. The value of the forest products increased from $1,724,378 in 1899 to $2,949,732 in 1909.

The leading horticultural crops are fruits and nuts, the products of which were valued at $49,917,655 in 1909; vegetables (including potatoes), the total acreage of which, in 1909, was 151,962, and their value $12,121,958; flowers, plants and nursery products, the acreage of which was 5,816 in 1909, an increase of 62.2 per cent since 1899, and their value $3,601,301; and small-fruits comprising an acreage of 9,687 in 1909, an increase of 54.2 per cent since 1899. The value of the small-fruits in 1909 was $1,789,214.

The total quantity of orchard-fruits producted in California in 1909 was 31,501,507 bushels, valued at $18,358,897. Plums and prunes, peaches and nectarines, apples and apricots are the most important of the orchard-fruits. In 1909, there were produced 9,317,979 bushels of plums and prunes, valued at $5,473,539; 9,267,118 bushels of peaches and nectarines, valued at $4,573,775; 6,335,073 bushels of apples, valued at $2,901,662; and 4,066,823 bushels of apricots, valued at $2,768,921. Of the orchard-fruits of less importance, there were produced in 1909, 1,928,097 bushels of pears, valued at $1,660,963; 501,013 bushels of cherries, valued at $951,624; and 32,638 bushels of quinces, valued at $26,266, together with 52,766 bushels of mulberries, valued at $2,147.

The production of grapes in 1909 amounted to 1,979,686,525 pounds, valued at $10,846,812. The number of vines of bearing age in 1910 was 144,097,670; those not of bearing age, 39,526,319.

The production of nuts in 1909 was 28,378,115 pounds, valued at $2,959,845. Most of the nuts were Persian or English walnuts and almonds, there being produced in 1909, 21,432,266 pounds of the former, valued at $2,247,193 and 6,692,513 pounds of the latter, valued at $700,304. The production of other nuts and their value are as follows: 159,374 pounds of black walnuts, valued at $2,562; 44,955 pounds of pecans, valued at $4,632; 37,153 pounds of chestnuts, valued at $3,474; and 4,550 pounds of Franquette, valued at $910.

The value of the tropical fruits in 1909 was $16,752,101, an increase from $7,219,000 in 1899. The value of oranges represents three-fourths of this total, and the value of lemons is next in importance. In 1909, the production of oranges was 14,436,180 boxes, valued at $12,951,505; that of lemons 2,756,221 boxes, valued at $2,976,571; that of olives, 16,132,412 pounds, valued at $401,277; that of figs, 22,990,353 pounds, valued at $260,153; and that of pomelos (grapefruit), 122,515 boxes, valued at $143,180. Other tropical fruits grown in California are loquats, tangerines, guavas, Japanese persimmons, pomegranates, mandarins and dates.

Strawberries are by far the most important of the small-fruits raised in California, with raspberries and loganberries, and blackberries and dewberries ranking second and third, respectively. The total production in 1909 was 26,824,120 quarts, as compared with 14,852,000 quarts in 1899. The acreage of strawberries increased from 2,418 in 1899 to 4,585 in 1909; the production in 1909 was 15,694,326 quarts, valued at $1,149,475. The acreage of raspberries and loganberries increased from 987 in 1899 to 1,992 in 1909; the production in 1909 was 5,222,117 quarts, valued at $304,169. The acreage of blackberries and dewberries increased from 1,960 in 1899 to 2,576 in 1909; the production in 1909 was 4,898,524 quarts, valued at $282,383. The production of the other small-fruits, and their value, in 1909, was as follows: currants, 852,378 quarts, valued at $43,508; gooseberries, 145,119 quarts, valued at $9,086, and cranberries, 10,656 quarts, valued at $443.

Of the vegetables grown in California, potatoes, sweet potatoes and yams are the most important. The acreage of potatoes in 1909 was 67,688, an increase of 60.8 per cent from that in 1899, when it was 42,098. The production of potatoes, in 1909, was 9,824,005, valued at $4,879,449. During the same period, the acreage of sweet potatoes and yams increased 218 per cent; an increase from 1,607 acres in 1899 to 5,111 acres, in 1909. The production in 1909 was 572,814 bushels, valued at $355,624. The leading vegetables, other than potatoes, sweet potatoes and yams, their acreage, and value in 1909 follow: asparagus, 9,399 acres, valued at $448,694; green beans, 7,646 acres, valued at $309,439; cabbage, 3,647 acres, valued at $306,858; cantaloupes, 5,784 acres, valued at $406,944; celery, 2,881 acres, valued at $381,759; onions, 4,391 acres, valued at $472,808; tomatoes, 5,932 acres, valued at $504,704; and watermelons, 6,065 acres, valued at $255,977. Among the other vegetables grown were beets, carrots, cauliflower, sweet corn, cucumbers, lettuce, green peas, green peppers, rhubarb, turnips, and squash.

The total acreage of flowers and plants in 1909 was 1,013, as compared with 672 in 1899. The number of square feet under glass in 1909 was 5,037,132, of which 4,422,423 were covered by greenhouses and 614,709 by sashes and frames. The value of the products from flowers and plants in 1909 was $1,388,513.

The acreage of nursery products increased 64.8 per cent from 1899 to 1909, the number of acres being 4,803 in 1909, as compared with 2,914 in 1899. The value of the nursery products in 1909 was $2,212,788, as compared with $558,329 in 1899.

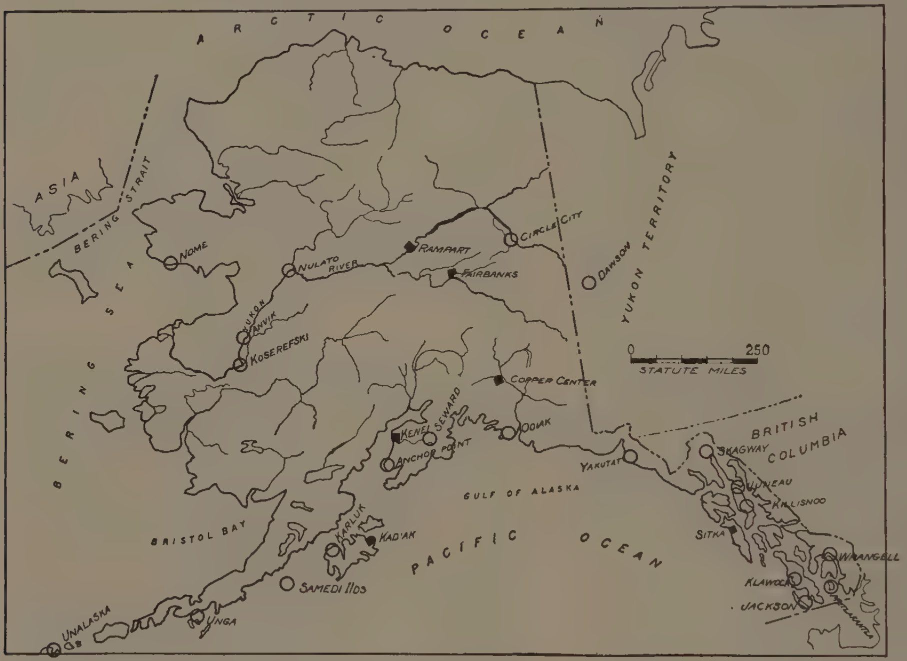
Charles H. Shinn.

ALASKA.

When considered from a horticultural or agricultural point of view, Alaska (Fig. 2535) may be very conveniently divided into two divisions, the southern coast region and the interior. These two regions differ very materially in their climate, and may be ultimately found as unlike in their possibilities. The climate of the coast region, which extends from Dixon's Entrance on the southeast to Unalaska on the southwest, is characterized by a heavy rainfall, a great preponderance of cloudy weather, and a rather low summer temperature, with little or no diurnal variation in the readings of the thermometer. The winter temperature is not excessively cold, zero weather being seldom experienced, while in the summer it is seldom high. The average rainfall, as shown by data from the Government Weather Service, varies between 55.9 inches at Killisnoo to 112 inches at Sitka, 113.6 inches at Unalaska, and 144.5 inches at Fortman Fish Hatchery, about one-third of the precipitation falling during the growing period, from May to September. The data concerning the interior portion of the country are mainly from along the Yukon River, that being the great thoroughfare of the region, and also from the valleys of the Tanana and Copper rivers. Here the rainfall is slight, varying between 9.31 inches at Copper Center, 10.8 inches at Rampart, and 13.6 inches at Fairbanks, and during summer clear skies are the rule. The intense cold of winter is followed by comparatively warm temperature in the summer, with a growing period of about four months, although occasional frosts have been reported from the upper part of the valley during the summer months. Maximum temperatures of above 90° F. have been reported from a number of interior stations. The regions about Cook Inlet and the lower part of the valley of the Susitna River have an intermediate climate, more rainfall than the interior valleys, and colder winters than those of the coast region.

The soils of the two regions, which in many places are thin and from various causes quite acid in reaction, are very similar, being largely of vegetable origin overlying rock or glacial deposits. In the coast region, arable areas are confined to rather narrow valleys and the slopes along the sea. In the interior are reported more extensive areas of comparatively level land. Of the coast region, the most extensive area of land adapted to cultivation is that on the Kenai Peninsula, and, extending across Cook Inlet, is continued up the Susitna River. This region, on account of its position relative to ocean currents, partakes more of the climatic characteristics of the interior, although still somewhat modified.

The accompanying map shows regions where some attempts have been made in gardening, from which definite reports have been secured. From the data at hand it seems probable that the local supplies of hardy vegetables might be produced nearer at hand than the Puget Sound. This is undoubtedly true of many parts of the country, where the production need be limited only by the demand for such supplies and the ability to secure arable lands at a cost that will permit the producer to compete with the Sound country. For some time certain economic features will enter into the subject of extensive horticulture. Among these are the high price of labor, the standard being at present determined by the wages paid for gold-mining, the question of transportation, and the rather limited markets.



2535. Alaska.

As it exists at the present time, horticulture in Alaska is of a very primitive type. A few gardens here and there, with perhaps a row of berries along the side and an occasional fruit-tree, represent nearly all that is done along this line. Near all the more important towns are market-gardens of considerable importance, but elsewhere only small areas are cultivated.

It has been said that during the Russian occupancy of the country, many attempts were made to cultivate gardens and fields, but the data are often so meager and contradictory as to throw doubt upon the sincerity of the endeavor. In the accompanying account, it is desired to place on record some of the horticultural achievements as gathered from reports from gardeners in many places, the personal observations of the writer during two seasons in the country, and the results of experiments conducted at experiment stations which have been maintained by the United States Department of Agriculture for ten or more years at Sitka, Fairbanks, Rampart, Copper Center, Kenai, and Kodiak. At all these places trials have been conducted of all the more important vegetables, and at Sitka of a considerable number of fruits and berries, as well as various ornamentals.

The great abundance, both in kind and quantity, of native fruits, especially berries, has doubtless contributed to the delay in the attempted introduction and cultivation of other sorts. Some early effort was made in this line, as is shown by the presence at Sitka of a number of old apple trees, remnants of the Russian days, which bear a very inferior fruit. A few young bearing trees of unknown variety are grown at the same place. At Wrangell, there were in 1898 apple trees of what were thought to be the Red June variety in bearing, and young thriving trees are known at Juneau and Metlakahtla. The mountain-ash (*Sorbus sambucifolia*) is grown as an ornamental tree. Attempts have been made at a number of places to cultivate some of the indigenous fruits, and the dewberry or "knesheneka" (*Rubus stellatus*), wild currants (*Ribes rubrum* and *R. bracteosum*), and the strawberry (*Fragaria chiloensis*) have all been domesticated, and their fruit is fully equal, if not superior, to the wild product.

At the Sitka Station, a number of apple trees, representing thirty or more varieties of crab, Russian, and other early apples, plum trees, and cherry trees have been under observation in the nurseries for several years. In 1911, five varieties bore mature fruit. These varieties were Yellow Transparent, Raspberry, Sylvan Sweet, Whitney, and Hyslop. In 1915 the first three varieties and Tetofsky ripened fruit. Among several varieties of cherries tested, Early Richmond has done the best and it has borne a light crop for several years. Of the plums planted, all have bloomed profusely, but none has as yet borne any fruit. The small bush-fruits thrive well over southeastern Alaska and the currant and raspberry have been successfully grown in the interior. Currants, both red and black, are indigenous to Alaska, and many of the improved varieties have been successfully introduced and distributed by the stations. Gooseberries also do well along the coast region, and they do not seem as subject to mildew as when grown elsewhere. Whitesmith, Columbus, Industry, Triumph, and Champion are varieties of gooseberry that have been successfully grown at the Sitka Station. Among the cultivated raspberries, Cuthbert does the best of any thus far tested. The fruit produced is large and well flavored, and the bushes are quite hardy. It has a long fruiting period, being in bearing at Sitka from August to October. Experiments with blackberries, dewberries, loganberries, and grapes have thus far resulted in failure. The wild salmon berry is widely distributed throughout Alaska, especially in the southeastern part. Crosses have been made between this and the cultivated raspberry, but the fruits thus far produced have been of very ordinary character. Strawberries are grown to some extent and at the Sitka Station hybrids have been made between a cultivated fruit of unknown origin and the native coast species of Fragaria, with the result that about thirty varieties exceeding the parent plants in all desirable qualities have been produced and are being propagated. The plants have proved absolutely hardy and the fruit is of large size and good quality.

More attempts have been made to grow vegetables than fruits, and some definite data have been obtained, showing what varieties are known to be adapted to Alaskan conditions. Most of the earlier data have been secured from Sitka and Wrangell, in the southeastern part of the country, and from the Holy Cross Mission, near Koserefski, on the lower Yukon. A report from the latter place states that potatoes of fine quality, weighing one and one-fourth pounds, and turnips weighing five and one-half pounds, were grown during the summer of 1898. In addition, notes were given of some of the varieties of vegetables adapted to the region, as follows: cabbage—Early Jersey Wakefield, Flat Dutch, and Drumhead; cauliflower—Early Snowball, Early Dwarf Erfurt; turnips—Early Flat Dutch, Yellow Globe, and Extra Early Milan; rutabagas—Improved American; radish—French Breakfast and Chartier; onions—Extra Early Red and Yellow Danvers; lettuce—Golden Heart; peas—American Wonder and Early Alaska; beets—Eclipse and Edmand's Blood Turnip; carrot—Oxheart; parsley—Extra Early Double Curled; celery—White Plume, Giant Pascal; rhubarb—Victoria.

The same varieties, with numerous additions, have succeeded in the coast region as well as at interior points. Snap beans, Challenge Black Wax, and Golden Wax have done fairly well at Sitka, where experiments were begun by the United States Department of Agriculture in 1898, and the English Windsor is quite in its element. At this place the Philadelphia Butter and San Francisco Market lettuce made fine heads of a most superior quality. Parsnips and carrots grow well, and salsify and spinach were successfully grown at Sitka, in 1898, for perhaps the first time. Peas were found to grow and yield well, and, in addition to the varieties above given, some of the dwarfs and the Norwegian sugar peas continued to produce their crop until cut off by the frost. The blood beets, Extra Blood Turnip and Extra Early Egyptian, grew well at Sitka, but in many places beets are a failure on account of their tendency to run to seed. This undesirable trait on the part of biennial plants is shared by other vegetables, principally turnips, although cabbage and cauliflower have been reported as doing likewise. It is believed by some growers that the flat type of turnip is more subject to run to seed than the globe type. Celery of exceedingly fine quality is grown at a number of places, although at Kodiak specimens have been seen in which the central axis was greatly elongated. The leafstalks were also lengthened in about the same proportion, and this trait was not considered undesirable.

Potatoes are more extensively grown in Alaska than any other crop, and the quality varies with the variety, locality, season, and culture. Usually little choice is exercised in the matter of varieties, but Eureka, Freeman, Early Ohio, Gold Coin, and Irish Cobbler appear well adapted to the conditions existing in this region. The two last are the best yielding varieties, and very favorable reports have been received from them wherever tried. Season and method of planting undoubtedly exert a strong influence on the crop. If the soil, which usually contains a high proportion of organic matter and moisture, is well drained or thrown up into beds, as is the custom in many places, good potatoes can be grown in the average season. Field trials of potatoes at the Rampart Station in 1911 gave yields at the rate of over 300 bushels an acre for Irish Cobbler, Gold Coin, and Eureka. Sprouting the tubers in flats in the light for two or three weeks before planting has been found advantageous in securing better quality and maturity of potatoes. In some parts of the country, especially from Cook Inlet westward, the natives until recently cultivated a small round potato, called the Russian, that seemed to be well suited to the country. It is said to have been brought from Siberia fifty or more years ago. Close planting of potatoes, as well as almost every other vegetable, is too often the rule, and to this fact alone may be attributed many failures. The object seems to be to grow a large crop by planting an abundance of seed. The result is a large growth of tops that completely shade the ground, thinning being seldom or never practised. Along the coast, where cloudy weather is the rule, it is safe to say that the sun's rays never strike the ground after the growing season has become well advanced. Under such conditions it is not an uncommon sight to see a crop of small potatoes borne in the axils of the leaves above ground, no tubers being formed below the surface.

Enough is now known of Alaska to warrant the claim that radish, mustard, turnips, kale, and lettuce can be grown anywhere up to the Arctic Circle, and, in favorable localities, even farther north than that. Carrots, parsnips, parsley, peas, cress, cabbage, cauliflower, brussels sprouts, onions, spinach, beets, rhubarb, potatoes, and mint, sage, thyme, and caraway among the herbs, can be grown along the coast and in the interior almost to the Arctic Circle if gardens are selected with reference to soil and exposure to the sun. Asparagus, beans, celery, cucumbers, squash, and salsify can be grown if planted in warm spots and given proper care and attention. In favored localities, especially about Hot Springs near Fairbanks, sweet corn, melons, tomatoes, eggplants, and other tender plants are successfully grown and on account of their rarity command high prices.

In general, considerable judgment is shown in the choice of garden sites. A southwestern slope is always preferred, and, if well drained, the garden is usually a thrifty one. In many places, the earth is thrown up into beds 4 or 5 feet wide and the crop planted crosswise the beds. Where it can be easily obtained, sand is added to warm and to lighten the soil. Kelp is extensively employed as a fertilizer in some places near the coast, but its value when added to a soil already largely composed of vegetable debris is questionable. Market-gardens have been successfully maintained for years at Skagway, Dawson, Circle City, Fairbanks, and other of the great mining centers of the Yukon, and the dirt roof of the miner's cabin is frequently utilized for early gardens, the heat from within supplying the necessary warmth required for growing early radishes, onions, lettuce, turnips, and the like.

The abundance of native fruits, especially of berries, has already been mentioned, and an enumeration of some of them would seem not out of place. Of widest distribution are the salmon berries (*Rubus spectabilis*), two so-called cranberries (*Viburnum pauciflorum* and *Vaccinium Vitis-Idæa*), currants (*Ribes rubrum*, *R. bracteosum*, and *R. laxiflorum*), crowberries (*Empetrum nigrum*), huckleberries (*Vaccinium uliginosum* and its var. *mucronatum*), blueberries (*V. ovalifolium*), red huckleberries (*V. parviflorum*), the molka or baked-apple berry (*Rubus Chamæmorus*) improperly called salmon berry in the interior, and raspberries (*Rubus strigosus*). Of less general distribution, yet very abundant in places, may be mentioned strawberries (*Fragaria chiloensis*), dewberries (*Rubus stellatus*), thimble berries (*R. parviflorus*), salal (*Gaultheria Shallon*), bog cranberries (*Vaccinium Oxycoccus*), bearberries (*Arctostaphylos alpina*), and so on.

Floriculture is not wholly neglected in Alaska, although but few data are available. Many of the hardier plants of the old-fashioned flower-garden are to be seen. Pansies of great size and brilliant color are common, and they remain in flower all summer. In some parts of the country sweet peas do well, and poppies, nasturtiums, mignonette, sweet alyssum, chrysanthemums, stock, candytuft, verbenas, and marigolds are not uncommon where any attempt is made to grow flowers. Window gardens and boxes add many sorts to the list already given.

Among ornamental perennials that have succeeded well with slight protection, or at Sitka with none, are phlox, milfoil, poppies, buttercups, columbines, iris, spirea, *Rosa rugosa*, Tartarian honeysuckle, and the like.

Experiments conducted under the direction of the Office of Experiment Stations, United States Department of Agriculture, at its stations and in coöperation with gardeners throughout the Territory for more than twelve years, have shown that much can be accomplished in various lines of horticulture if rational methods of culture and a proper selection of varieties and seed are followed. The possibility of locally producing seed of peas, turnips, rutabagas, mustard, and potato seed tubers has been fully demonstrated, and wherever such seed is planted better crops are almost invariably secured.

But little trouble has been met with from fungous diseases and insect pests, except for some mildews of apple, gooseberry, and currant, and from a root maggot that attacks many cruciferous plants. Spraying for the mildews, and rotation, and varietal selection have proved valuable aids in combating the root maggot. A variety of turnips, Petrowski, has proved quite resistant to their attack wherever it has been tried.

For further information, consult Yearbook of Department of Agriculture for 1897; Office Experiment Stations, United States Department of Agriculture, Bulletins Nos. 48 and 56; Alaska Experiment Stations, Bulletin No. 3, and Reports 1898 to 1914.

Walter H. Evans.

NOTHOCHLÆNA: *Notholæna.*

NOTHOFÀGUS (Greek words, meaning *not a true beech*). *Fagàceæ.* A genus of about 12 species, native of S. Amer., Austral. and New Zeal., closely allied to Fagus, but chiefly distinguished by the fls., both staminate and pistillate ones being borne in 3's or solitary. The lvs. are generally small, often evergreen and either plicate in bud, like those of Fagus, or not. The wood of some species, especially that of *N. Dombeyi* and *N. procera*, in Chile, and of *N. Cunninghamii*, in Austral. is much valued. They are not hardy in the N., and but little known in cult. The two following species have been recently intro. by the Dept. of Agric. **N. oblìqua,** Blume (*Fàgus oblìqua*, Mirb.). Deciduous tree, attaining 100 ft.: young branchlets glabrous: lvs. ovate-oblong, acutish or obtuse, oblique at the base, serrate, lobulate below the middle, glabrous or nearly so, with 8–11 pairs of veins, 1–2½ in. long: involucre 4-valved: nuts 3, 2 triangular and 3-winged, 1 flattened and 2-winged. Chile. **N. procèra,** Oerst. (*Fàgus procèra*, Poepp. & Endl.). Similar to the preceding: lvs. oblong, rounded at both ends, doubly crenate-serrate, pubescent beneath, up to 4 in. long. Chile.—The following 6 species have been intro. into European gardens and have proved fairly hardy in S. England and Ireland. *N. antárctica*, Oerst. (B.M. 8314, var. *uliginosa*. J.H. S. 37:53), *N. betuloìdes*, Oerst. (G.C. 1872: 467; II. 25:105; III. 33:11), *N. Cúnninghamii*, Oerst. (B.M. 8584), *N. cliffortioìdes*, Oerst., *N. fúsca*, Oerst., and *N. Mooèrei*, Krasser. They are all trees or sometimes shrubby, with small, ovate or elliptic crenate-dentate lvs., ½–1 in. long. The first one is deciduous, the others evergreen. They are perhaps oftener enumerated under Fagus, but besides the difference in the fls. they are different in habit, especially on account of their very small lvs., large only in *N. procera*. Prop. is by seeds or by layers.

Alfred Rehder.

NOTHOLÆNA (Latin, *spurious, cloak;* from the rudimentary indusium). *Polypodiàceæ.* Often written *Nothochlæna*, but the above is Robert Brown's original orthography. A group of mostly warm temperate rock-loving ferns, differing from Cheilanthes mainly in having no marginal indusium. Some of the species are coated with a golden or silvery wax-like powder. The following have been advertised only once by a dealer in native plants. Culture as in Cheilanthes, pages 734 and 1217.

A. *Foliage densely scaly beneath.*

B. *Lvs. once-pinnate.*

sinuàta, Kaulf. Lf.-blades 1–2 ft. long, 1–3 in. wide, growing on short stalks from thick, scaly rootstocks; pinnæ thick, entire or deeply pinnatifid; lower surface with rusty scales. S. W. U. S. to Chile.

ferrugínea, Hook. Lf.-blades 6–12 in. long, ½–1 in. wide, growing on wiry black stalks from thick, dark, scaly rootstalks; pinnæ deeply pinnatifid, with blunt lobes; texture thinner; lower surface densely matted with wool. S. W. U. S. to W. Indies and Chile.

BB. *Lvs. 3- to 4-pinnate.*

Néwberryi, D. C. Eaton. Cotton Fern. Lf.-blades 3–5 in. long, on stalks of the same length; ultimate segms. ⅓–½ line wide, covered on both sides with slender, entangled hairs, which are more dense on the under surface. Calif.

Párryi, D. C. Eaton. Lace Fern. Lf.-blades 2–4 in. long, tripinnate, with crowded roundish obovate segms. 1 line wide, which are densely covered above with entangled white hairs, beneath with a heavier pale brown wool. Utah to Calif.

AA. *Foliage with white or yellow powder beneath.*

cretàcea, Liebm. Rootstock short, with rigid scales: lf.-blades 1–2 in. each way, pentagonal on brownish stalks 2–7 in. long; ultimate segms. oblong or triangular-oblong, crowded. S. Calif. and Ariz.—Less handsome than the similar but larger and less divided *N. Hookeri* of Texas to Ariz.

cándida, Hook. Rootstock creeping: lf-blades 3–6 in. long, ovate or deltoid-ovate, pinnate; lowest pinnæ with inferior pinnules elongated and again pinnatifid; upper surface green. Texas and New Mex.

AAA. *Foliage naked below.*

ténera, Gillies (*Pellæa ténera*, Prantl). Lf.-blades 3–4 in. long, ovate-pyramidal, 2–3-pinnate; pinnæ distant, with ovate or subcordate, smooth, naked segms. S. Utah and Calif. to Bolivia.—Very rare.

L. M. Underwood. R. C. Benedict.†

NOTHÓLCUS (Greek, *nothos*, false, and *Holcus*, the name formerly applied to this group). *Gramíneæ.* Perennials with woolly or downy flat blades and narrow panicles: spikelets 2-fld., the lower floret perfect and awnless, the upper staminate and awned.—Species about 8, Eu. and N. Afr.

lanàtus, Nash (*Hólcus lanàtus*, Linn.). Velvet-Grass. Two to 3 ft. high: blades velvety: panicle greenish or purple-tinged. Dept. Agric., Div. Agrost., 20:89. Eu.—A forage grass of poor quality but of some value on sterile soil. A variegated form is cult. abroad for ornament.

A. S. Hitchcock.

NOTHOPANAX: Discussed under *Polyscias.*

NOTHOSCÓRDUM (Greek, *false garlic*). *Liliàceæ.* Herbs having an onion-like bulb and closely related to Allium.

Bulb tunicated, without the onion odor and taste: scape 6–12 in. high: lvs. several, linear, basal, 6–12 in. long: fls. yellow or white, in an umbel; style obscurely jointed; ovary 3-loculed; ovules several in each locule: caps. oblong-ovate, somewhat lobed, obtuse.—About 10–20 species mostly found in Trop. S. Amer., 1 in China and at least 1 in N. Amer. The species in this genus are variously placed under Allium and Ornithogalum by some authors.

bivâlve, Brit. (*N. striàtum,* Kunth. *Ornithógalum biválve,* Linn.). Yellow False Garlic. Streak-leaved Garlic. Bulb globular, 1 in. through, sometimes bearing bulblets at base: scape 1 ft. or less high: lvs. 7–8 in. high, 1/12–⅙in. broad, flat, blunt, shorter than scape or equaling it: fls. yellowish, 6–12 in an umbel on slender pedicels, the segms. narrowly oblong, 4–6 lines long; ovules 4–7 in each cell. Early spring. Va. to Ohio, Tenn., Neb., Fla., Texas, and Mex.—Hardy. Procurable from dealers in native plants.

fràgrans, Kunth (*Állium fràgrans,* Vent.). Bulb larger, round, yellowish white: lvs. linear, obtuse, 8–12 in. long: scape rotund, attaining height of 20 in.: spathe 2-parted, shorter than pedicels: fls. fragrant, 8–20 in an umbel, white slightly blushed, lined dark; stamens and anthers purplish. Subtrop. Amer.—Not very hardy; better treated as a tender bulb and dug up in fall, planting in spring. A. C. Hottes.†

NOTÒNIA (named for an English botanist, Noton). *Compósitæ.* About a dozen fleshy herbs or undershrubs, of Trop. Afr. and Asia, by many botanists included in Senecio. Heads discoid (without rays); style-branches with ovate or lanceolate papillose extremities: otherwise as Senecio: lvs. rudimentary or succulent, and the yellow or red heads rather large, solitary or cymose. They are to be treated like kleinias and various succulent tropical senecios; grown mostly as oddities and little known to gardeners.

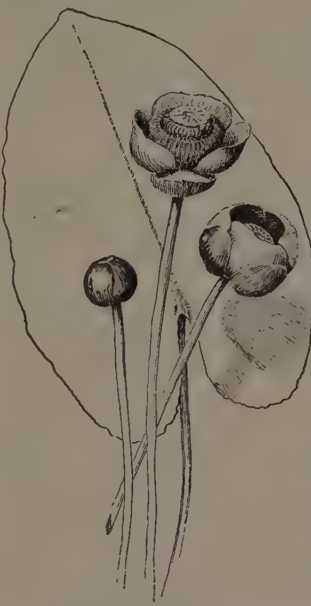
N. amaniénsis, Engler. Lvs. spatulate, fleshy, about 6 in. long and ½in. wide: scape rising to 4 ft., with 3 or more heads of yellow fls. on long reddish peduncles. E. Trop. Afr. *N. Grántii,* Oliver & Hiern. (*Senècio lóngipes,* Baker. *Kleìnia Grántii,* Hook. f. *N. sempérvirens,* Asch.). Short fleshy glaucescent plant: st. 4–8 in. high from a tuberous root, decumbent, bearing the peduncle at the summit: peduncle scape-like, with a few linear scale-like lvs. and bearing about 2 or 3 stalked orange-scarlet heads. B.M. 7691. G.C. III. 45:227. If this plant is the same as the *Cacalia sempervirens,* Forsk., it must then bear the name *N. sempervirens,* Asch. L. H. B.

NOTOSPÁRTIUM (name from *Spartium* or broom). *Leguminòsæ.* Two shrubs, leafless at maturity, with compressed pendulous branches, of New Zeal., one of them more or less planted in Great Britain. Fls. papilionaceous, rather small, in lateral racemes; calyx 5-toothed, campanulate; standard obovate or obcordate, clawed and somewhat reflexed; keel hatchet-shaped and obtuse; wings shorter than the keel, oblong, auricular at base; stamens 9 and 1: pod linear and many-jointed (and in this differing from Carmichælia). *N. Carmichǽliæ,* Hook. f. Pink Broom. Much-branched, to 10 ft. high, the branches glabrous and bearing alternate scales, the lvs. (only on young plants) 1-foliolate and orbicular or obcordate: racemes 1–2 in. long, bearing pink fls.: pod about 1 in. long. S. Isl. of New Zeal. B.M. 6741. G.C. III. 42:146. Gn. 71, p. 428; 74, p. 143.—A rare and local plant in New Zeal., blooming there in summer (Dec.–Jan.). Hardy in the open at the Kew Gardens, England.

NOTỸLIA (*back* and *hump,* alluding to a lump or protuberance on the column). *Orchidàceæ.* About 20 Trop. American orchids of the Vandæ group, little grown. They need warmhouse treatment. Small low plants, with plane coriaceous or fleshy lvs.: fls. inconspicuous, white, greenish or yellow, on radical racemes; sepals equal, narrow, erect or becoming spreading, free or the 2 lateral ones connate; petals resembling the sepals; lip unguiculate, entire, sometimes slightly adnate to the column; pollinia 2, waxy, not appendaged. *N. bícolor,* Lindl. "Whole plant not more than an inch and a half high: lvs. generally about 5, equitant, stiff, acuminate, scimitar-shaped, scarcely half the length of the fl.-spikes." Sepals white, and petals lilac with blue spots at base, lip lilac: spikes drooping. Guatemala. B.M. 5609. *N. trisépala,* Lindl. & Paxt. Epiphytic: pseudobulb ½in. long, 1-lvd.: lvs. oblong, to 3 in.: scape pendulous, about ½ft. long, with a many-fld. raceme of pale green very small fls. with scoop-shaped lip. Mex. B.M. 8306. *N. sagittífera,* Hook. (*Pleurothállis sagittífera,* HBK. *N. multiflòra,* Lindl.). Stemless parasite: lvs. distichous, deciduous, oval-lanceolate, nerveless: spikes axillary, many-fld., cernuous, the fls. bright rose-color. Guiana. L. H. B.

NÙPHAR (from the Arabic). *Nymphǽa* of some authors. *Nymphæàceæ.* Spatter-Dock. Yellow Pond-Lily. Several aquatic plants of the North Temperate Zone, with stout rootstocks creeping in the mud.

Leaves large, cordate-ovate or sagittate, some of which may be submerged and others either floating or standing erect above the water: fls. usually standing above the water, yellow or purplish, single on the scapes, the 5 or more large concave sepals constituting the showy part of the fl.; petals mostly numerous, small and simulating stamens, the latter numerous and short; ovary short, globular-ovoid, with 8–24 stigmas forming rays on its top: fr. an emersed caps.—Most of the nuphars are N. American. They grow in stagnant pools or on the margins of slow-running mud-bottom streams. Several species have been offered by dealers, but most of them have small value for the cultivator, although the foliage effects of *N. advena* may be striking. For cult., see *Nymphæa* and *Aquatics.*—The N. American species are monographed by Miller & Standley in Contrib. U. S. Nat. Herb. XVI, part 3 (1912). The nomenclature is discussed under Nymphæa.



2536. Nuphar advena. (×⅙)

A. *Lvs. mostly cordate-ovate.*

B. *Plants strong and large.*

ádvena, Smith. Common Spatter-Dock. Cow Lily. Fig. 2536. Lvs. large (about 1 ft. long), varying from roundish to ovate or almost oblong, thick, with a deep and mostly open basal sinus, the lower surface often pubescent; petioles terete; submerged lvs. usually wanting: fls. 2–3 in. across, more or less globular (not wide opening), yellow, mostly tinged with green or brown; petals shorter than the stamens, fleshy and truncate; sepals 6; stigma nearly entire, yellow or pale red, 12–24-rayed. N. Y., southward and westward. Mn. 1:17. G.C. II. 20:557 V. 2:197. Var. **variegàtum,** Engelm., with floating lvs. only (none erect), closed sinus, petioles flat on one side and fls. partly purple, occurs from New Bruns. to Brit. Col., Iowa, N. Ohio, and the mountains of Pa.

rubrodíscum, Morong. Lvs. somewhat smaller; submerged lvs. usually present: fls. 1–1½ in. across, yellow; sepals 5–6; stigma crenately toothed, bright red or crimson, 9–13-rayed. New Bruns. to Mich. and Pa.

polysépalum, Engelm. Larger than *N. advena*, the lvs. three-fourths as broad as long, erect in shallow water and floating in deep water: fls. 4–5 in. across, yellow, the sepals 9–12, and the petals 12–18, cuneate. Colo., Wyo. and northwestward.

lùteum, Sibth. & Smith. EUROPEAN YELLOW POND-LILY. Lvs. cordate-ovate, floating or rising little above the water; petiole triangular: fls. yellow, somewhat fragrant, smaller than those of *N. advena*, the sepals 5, petals very numerous; stigmas 10–30-rayed, with entire margin. Eu.

BB. *Plant slender, often delicate.*

mínimum, Reichb. (*N. pùmilum*, Smith). Slender: lvs. small, oblong, with a deep sinus and spreading lobes; petiole slender, 2-edged: fls. 1 in. or less across, yellow; sepals 5; petals 9–12; stigma 8–12-rayed, yellow, margin prominently indented. Eu.—Easily cult. and free-flowering.

microphýllum, Pers. (*N. Kalmiànum*, R. Br.). Very slender, with prominent submerged lettuce-like lvs., the emersed ones floating and only 3 or 4 in. long: fl. 1 in. or less across, yellow, with 5 sepals and thin spatulate petals; stigma 7–10-rayed, dark red. New Bruns. to Pa. and Minn. and southward.

AA. *Lvs. long-sagittate or narrow-oblong.*

sagittæfòlium, Pursh. Rather stout: emersed lvs. floating, about 1 ft. long and 2–3 in. wide, sinus open; submerged lvs. similar in shape, crispate, numerous: fls. 1 in. across, yellow, the sepals 5, the petals spatulate; stigma 11–15-rayed: fr. almost cylindric. N. and S. C.

japónicum. DC. Similar to the last. Submerged lvs. large, crisped: fl. 2–3 in. across: fr. flask-shaped. Japan. —A form with red-tipped stamens and sepals is cult.

HENRY S. CONARD.

NURSERY: in horticulture, an establishment for the rearing of plants. Properly, a nursery exists for the rearing of any kind of plant, but in America the word is restricted to an establishment devoted to the growing of hardy, more particularly woody plants. This is because of the early and great development of orcharding and tree-planting and the relative infrequency at that time of glass structures and private estates employing gardeners.

In North America the nursery business, as we now know it, is practically an institution of the last century, although there were nurseries more than a century ago. Consult pages 1516–1518 for an historical sketch of the nursery business; also in Vol. III the biographies of nurserymen, as Barry, Berckmans, Brackett, Bush, Cole, Conard, Dartt, Douglas, Downer, Ellwanger, Garey, Heikes, Hogg, Hoopes, Hovey, Kenrick, Kerr, Lewelling, Manning, Meehan, Moon, Munson, Parsons, Prince, Ragan, Reasoner, Rock, Roeding, Saul, Saunders, Shinn, Smith, Stark, Teas, Thomas, Wharton, Woolverton, and others.

As early as 1768, according to J. H. Hale, the New York Society for Promotion of Arts awarded Thomas Young a premium of £10 for the largest number of apple trees, the number being 27,123 But the large trading nursery developed simultaneously with the great orchard-planting industry which began in western New York and extended westward, and, since the Civil War, to the southward. The largest nursery center of North America, considering the number of persons engaged and the variety of stock grown, is western New York, with headquarters in Rochester. Nearly one-ninth of all the nurseries enumerated in 1890 were in New York state, and these establishments employed a capital of over $12,000,000. In 1909, New York still led in the value of nursery products. Very extensive nursery enterprises are now established in many other parts of the country, and it is probable that the center of the nursery business will move westward.

In America, nursery stock is grown on a broad or extensive rather than intensive scale. This is particularly true of fruit-trees. These trees are to be set in wide and open orchards, and the nursery practices are therefore very unlike those that obtain in Europe. In the latter country, for example, fruit-trees are trained in the nursery row to assume definite shapes. Some are trained for standards,—to grow to one straight, bare trunk. Others are trained for bush specimens, some for growing on walls and espaliers, some with round heads, some with conical heads, and the like. It is the pride of the American nurseryman, however, that his rows shall be perfectly even and uniform. Any break in this uniformity is considered to be a blemish. If every tree could be a duplicate of every other, his ideal would be attained. Ordinarily, fruit trees are trained to single stems, the top starting at 2 or 3 feet from the ground.

All fruit trees are budded or grafted. In early days, piece root-grafting the apple was a common practice in the eastern states; but it has gradually given way to budding and thereby a top is supplied with one whole strong root. In some places, however, root-grafting is still popular, partly because more than one tree may be made from an individual root, and partly because it allows the operator to use a long cion and to put the foster root far below the surface, thereby allowing the cion to send out its own roots and causing the tree to become own-rooted and to have a known hardiness.

In the use of whole roots, rather than pieces, there is apparently little or no difference in the orchard between the budded and grafted trees; but when grafting is performed on pieces of root, the results are likely to be unsatisfactory. Some varieties of apple, among which may be mentioned Grimes Golden, are not long-lived, being subject to collar-rot or other disabilities. To correct this fault, nurserymen double-work these weak varieties on the bodies of hardy long-lived, resistant trees such as Northern Spy and others.

There are many diseases and pests in the growing of all kinds of nursery stock, and these are now treated in official publications of government and experiment stations. The extent of these dangers has resulted in special laws and regulations to control the spread of pests and diseases. See *Inspection*, page 1647.

The most widespread and fundamental difficulty, however, is the inability to grow many crops of trees on the same land with good results. In fact, in the case of fruit-trees, it is usually considered that land which has been "treed" is therefore unfit for the growing of other fruit stock until it shall have rested in clover or other crops for a period of five years or more. Ornamental stock is often grown continuously on the same land with good results, even when the same species is grown. This is largely due to the fact that ornamental stock is sold by its size and not by its age, and therefore rapidity of growth is not so important as it is in the case of fruit-trees. It has been supposed that this necessity of rotation is due to the exhaustion of certain plant-food elements from the soil. It has been found by experiments, however, that such is not the case. The chief difficulty seems to be physical. Lands that are devoted to nursery stock for one crop, which is from two to five years, becomes void of humus, and the digging of the stock when the land is wet or unfit to be worked tends to impair the physical character of the soil. Experiments have shown that commercial fertilizers will not always reclaim lands which have been treed, whereas barn manures and green crops may go very far towards revitalizing them. As a result of inability to grow vigorous stock on treed land, a large part of the nursery stock of the country, particularly fruit trees, is grown on rented land. On the nurseryman's central grounds a variety of stock may be grown, chiefly ornamentals, but the larger part of the commercial fruit stock is farmed out to persons who are willing to rent their land for this purpose and who will give the requisite attention to the growing trees.

The industry has developed special tools without which nursery stock cannot be grown on a commercial scale. The simplest of these are budding- and grafting-knives of various kinds to meet the needs of different plants and the whims of users. There are also special hoes for planting and spades for digging, the latter with strongly reinforced handles and heavy blades of the best steel. Several tools in common use in subsoiling and cultivating are peculiar to nursery work. Still more specialized are the tree-diggers, requiring considerable power, drawn usually by four to eight teams, by traction engines, or by stationary engines at the end of the row which draw the digger by winding up a cable on a drum. Fall digging makes it necessary to strip the leaves of many trees, a task formerly performed by hand, but many growers now strip in a specially made machine after the trees are dug. Besides these, various devices are used in packing and boxing.

2537. View in an American apple tree nursery.

Winter storage. (U. P. Hedrick.)

Nurserymen in the North almost universally dig tree-, bush- and vine-fruits, as well as many ornamentals, in autumn and store through the winter in frost-proof houses of one kind or another. The best of these houses are built much as are cold-storage plants—in fact, some have facilities for refrigeration. By far the greater number of them, however, are storage cellars. The objects gained by winter storage are protection against mice and rabbits, prevention of injury through freezing and the wide fluctuations in temperature in northern winters, and greater convenience in making spring shipments. The most satisfactory results are secured when the stock is kept at a uniform temperature as near freezing as possible. Thus, at 28° to 34° F., above zero, very little ventilation is necessary, the trees dry out and shrivel but little, there is a minimum tendency to mildew, and packing material about the roots and spraying with water are usually not necessary. At lower temperatures, injury from freezing begins, and at higher ones the storage-house must be ventilated, the trees sprayed, their roots protected, and fungi do serious damage. Undoubtedly the storage of stock benefits the nurseryman more than the fruit-grower; for it is because of the drying out, more or less of which always takes place, or other injury in poorly managed storage, that trees so often come to the grower with barely the breath of life.

The extent of the nursery business.

Statistics covering the general range of the United States nursery business were published in Bulletin No. 109 of the Eleventh Census (for 1890). The census enumerated the items of 4,510 nurseries, occupying 172,806 acres and representing a valuation of $41,978,835.80. The total capital invested was about $52,500,000. These establishments employed 45,657 men, 2,279 women, and 14,200 animals. The total number of plants and trees was 3,386,858,778, which figure does not include unenumerated plants on 1,477 acres of nursery grounds. Of this enormous total, fruit trees comprised 518,016,612 plants, and grape-vines and small-fruits 685,603,396. Apple trees alone, the highest figure given for a single species, numbered 240,570,666. It is probable that these early figures are not comparable in statistical value with those of succeeding censuses. It would be interesting to speculate as to the destiny of these trees and plants. It is safe to assume that each plant in this uncountable number was the subject of thought and solicitude on the part of the propagator; yet it is probable that not one in a hundred has lived to bring satisfactory reward to the buyer. It has been estimated that the apple trees standing in orchards in the United States at the close of the century were 100,000,000, or less than half the number growing in the nurseries in 1890. The elements of loss are many, but the greater part of the failures occur after the stock has passed to the hands of the final purchaser.

In the Twelfth Census (1900), "there were 2,029 commercial nurseries in the United States. Within the past decade many small nurseries have been consolidated and numerous others have been absorbed by the larger companies." "In many of the western states the owners of large orchards propagate from the standard varieties they have on hand the stock they require in enlarging their acreage of fruit trees. This has not been taken into account in compiling the statistics of nurseries because the income from this labor would be credited to sale of fruit and not to sale of trees." The total area was 165,780 acres, with 137,459 acres, or 82.9 per cent, improved. The average size of the nursery establishments was 81.7 acres, although a number of 500-acre tracts were operated. "The value of land, buildings, and other improvements was $18,144,073, the former value being $13,880,820 and the latter $4,263,253. The average value an acre of the land was $84. The value of buildings was much smaller for the nursery establishments than for the florists' establishments, and the value of live-stock much larger. This is due to the fact that nursery operations are much the same as in other farming. The value of implements was $539,895 and of live-stock, $462,013. The total value of products was $10,086,136 and $139,512 was expended for fertilizers and $2,305,270 for labor. One of the heaviest expenses of the nursery growers was that for labor, the amount constituting 22.9 per cent of the value of the product, a much larger proportion than is involved in the raising of other crops, except flowers and plants. The total value of products comprised $9,231,503 from nursery stock and $854,633 from general farm produce. Distributed among the 2,029 establishments reporting, it gives an average value of product of $4,971. The value of products fed was $192,999, a considerably larger proportion than for the florists.

"Of the several geographic divisions, the North Central ranks first, many new nurseries having been established to meet the greatly increased demand for nursery products in the West. In the North Central division there were 836 establishments, with a total value of products not fed to live-stock of $3,892,668.

The number of establishments and the value of products not fed to live-stock for the other divisions are: North Atlantic, 496, $3,076,241; South Central, 287, $1,347,253; Western, 241, $944,289; South Atlantic, 169, $825,685. New York leads in the quantity of nursery stock produced, being credited with over half of the total reported for the North Atlantic division. For many years the state has been prominent in this industry, it now having 237 establishments and products valued at $1,703,354. Some of the other leading states, in value of products, are: Iowa, $636,543; Illinois, $610,971; Ohio, $538,534; California, $533,038; and Pennsylvania, $515,010.

The Thirteenth Census (1910) reports the acreage in nursery products in 1909, as 80,618, "showing an increase of 35.5 per cent since 1899, while the value of the products more than doubled during the decade, amounting to $21,051,000 in 1909. The average value per acre increased from $170.17 in 1899 to $261.12 in 1909. Of the total value of nursery products 98 per cent was reported by 2,470 special nursery establishments, the aggregate value for such establishments being $20,620,000, and the average per establishment $8,348. The value of nursery products in 1909 was over $1,000,000 in every division except New England and the Mountain divisions. The Middle Atlantic division, with a product of $4,355,000, ranked first, followed in order by the West North Central and Pacific divisions each with a product valued in excess of $3,000,000. The three leading states in this respect were New York, with $2,703,000; California, with $2,135,000; and Texas, with $1,236,000; no other state producing as much as $1,000,000 worth."

The nursery interests of this country are represented in a strong organization known as the American Association of Nurserymen, which holds a movable annual meeting in June and publishes a report (see page 1553). There are also societies representing geographical regions. At the present time, there is one periodical devoted to the nursery business, "The National Nurseryman," which is published monthly at Rochester, New York. The American current book writings devoted specifically to the business are Fuller's "Propagation of Plants" and Bailey's "Nursery-Book."

L. H. B.

NUT-CULTURE. Seeds with a hard shell and edible kernel, which are classified colloquially under the head of nuts, are borne chiefly upon trees or shrubs. A few species of annual plants furnish nut crops. In most parts of the world nuts have been collected chiefly from wild seedling trees, but in some countries the hazel, the almond, and the walnut in particular have been grown in orchard form since very early times. Such grouping offers better facilities for cultivation and for gathering of the crops.

It is probable that the almond, which is very easily budded, has been subjected to that process since the days of the Romans. More recently the hazels and the walnuts have been propagated by budding and by grafting in the European countries. The larger part of nut orchards, however, have consisted of seedling trees of selected varieties. In the latter part of the nineteenth century there developed a widely extended movement, including several countries, toward grafting or budding particularly desirable varieties or species of nut-bearing trees or shrubs upon appropriate stocks. A still more advanced procedure,—that of hybridizing,—for the purpose of combining characteristics of especially desirable kinds, belongs almost peculiarly to the twentieth century. Nut-bearing trees which are chiefly wind-pollinized have been so extensively crossed in nature that few of them breed true to seed. They are much like the apple in this respect. The new movement of artificial pollinizing promises to accomplish for the nut-tree what it has accomplished for many other kinds of fruits. A notable development of the industry of nut-raising may be anticipated as a result of the application of modern methods.

Some species of trees, like the coconuts and the nut-bearing pine trees, apparently gain little or nothing from cultivation. Almonds, chestnuts, hickories, hazels and walnuts, on the other hand, are remarkably susceptible to influences of cultivation, and they respond with crops which are valuable largely in proportion to the degree of skilled attention which has been given by the horticulturist. Species of trees which have not as yet been cultivated for man's purposes, although valuable in some cases for mast crops for animals, will presumably be given much more attention in the future. Certain kinds, like the beeches and the oaks, may eventually furnish large quantities of food for man. Acorns, while rich in protein, fat and starches, contain in addition disagreeable elements like berberine or tannin in excess. These elements may be bred out to a greater or less extent by horticulturists. The horse-chestnuts of various species which bear heavy crops of nuts, valuable in food-content, are little used except by the Indians, who crush the nuts and wash out the soluble elements which are undesirable. It is probable that chemistry will eventually solve the question in such a way as to allow this group of trees to be grown for food purposes more generally.

Among the desirable kinds of nut-trees which have already been subjected to cultivation, it is found that grafting and budding bring out certain characteristics belonging to those of other fruit-trees, when subjected to the same process. There is apparently a tendency toward precocious bearing, and the grafted or budded nut-trees appear to be more prolific than others, and perhaps to be shorter-lived in consequence. A number of species of nut-trees which do not bear naturally until they are fifteen years or more of age as seedling trees, may begin to bear in one to three years after grafting or budding upon other stocks.

The methods of grafting or budding are in general those which are employed for other fruit-trees, but rather more expert work is required on the part of the horticulturist, and several factors have to be taken into consideration. In grafting or budding nut-trees which have particularly hard wood, very accurate work is required for the purpose of getting the cambium layers of stock and of insert neatly adjusted. The slow callusing of hardwood trees of this group requires particular care in the method chosen for protecting the inserts against drying out before granulation is completed. Some of the nut-trees, walnuts particularly, have such a free flow of sap that the method of placing inserts must be so adapted that this sap is allowed to escape freely, otherwise the dammed sap decomposes and destroys the callus.

The question as to whether grafting or budding is particularly desirable for any one species of nut-tree has not yet been determined. Some of the nut-tree growers in temperate regions prefer grafting in the spring, while others are convinced that August budding gives best results. Under these circumstances one is probably dealing with a matter of individual proficiency and skill, rather than with any fundamental principle in plant physiology which is involved in the question. Cions which are to be employed for spring grafting of nut-trees are best cut in the autumn. They may be stored in densely packed leaves or kept in cold storage until the following season. Sometimes they may be buried in sand. There is danger from the effects of too much moisture when cions are kept in sand, because the protoplasm of buds becomes senescent or undergoes chemical change when carrying a full charge of water. For August budding, two methods are employed. The leaves of the prospective bud-stick are cut off, leaving the petioles in place. At the end of a few days these petioles usually separate and fall away, leaving buds which are more readily handled. Other orchardists prefer to leave the petiole in connection with the bud and to transfer both directly to the stock. In any case it is important to make use of one principle,—the principle of bringing the bud to a state of rest for a few days. This is best accomplished by placing the green bud-sticks in the ice-house or in cold storage for three or four days. The effect of the cold is to bring the life processes in the buds to a pause, and then when transferred to stocks the buds start off into activity in a more kindly way than when transferred without a resting-period.

The choice of grafting-stocks is one of considerable importance. Almost any species or variety of nut-tree may be grown upon stocks of allied species and varieties, but in dealing with the hickories it is desirable to note the wide variation in character and texture of wood between different species. Thus the pecan, an open-bud species, will perhaps be found to thrive best when grown upon stocks of the bitternut (another open-bud species), excepting when it is more desirable for any reason to place a variety of pecan upon stocks of its own species. The shagbark hickory appears to do best upon stocks of shagbark, mockernut, shellbark or pignut. In chestnut-grafting, the various European, Asiatic and American examples are best grown upon stocks of their own kinds respectively. Some of the Asiatic species, for example, do not make firm ligneous union at the site of an insert upon an American stock. American chestnuts grafted upon European kinds are prone to make excessive growth without firm ligneous union, at least during the first two years. Sometimes wild nut-trees are grafted or budded with particularly desirable kinds, and this may be profitably accomplished if the wild trees are well headed back during the winter time, and new sprouts allowed to start in the spring. Grafting or budding is done upon the new sprouts subsequently. This work demands very much attention on the part of the horticulturist, because the large quantities of new shoots which start out from a mature tree may deprive grafted or budded sprouts of their sap. When the grafting or budding is to be done upon small stocks in the nursery, there is some question as to whether these stocks may be best grown where they are to remain permanently, or whether it is desirable to subject them to cultivation in close form for two or three years, and then transplant.

There is a tradition among horticulturists to the effect that nut-trees in general are not readily transplanted. This is not strictly true, but it includes the idea that much more care must be exercised when transplanting species of trees which have not as yet been brought under subjection through many generations of cultivation. The Stringfellow method of severe trimming back of the head and root, without any attempt at saving small fibrous roots, has been the most successful method with some horticulturists when nut-tree stocks were to be transplanted.

The choice of soil is an important matter in the growing of nut-trees. Chestnuts and hazels, for example, will thrive in soil that is somewhat acid, while walnuts and some of the hickories are insistent upon having neutral or alkaline soil. Species which naturally prefer neutral or alkaline soil will thrive very well as older trees upon soil that is slightly acid, provided that a little lime be added to the soil during the first four or five years of growth of the tree. Nut-trees, for the most part, when grown in orchard form, should be given the character of soil which wild trees of the same species are known to prefer. Lime in the soil is thought to improve the quality of many of the nuts, and in the best walnut orchards of France it is sometimes applied annually, even upon soil which is already neutral or alkaline in reaction.

Among the nut-bearing annual plants, various species of lotus and the water caltrops furnish an important food-supply in some parts of the Orient, but these are not as yet subjected to cultivation, and they have been neglected as sources of food-supply in America, although they are grown here in many places chiefly for their flowers or as curiosities. Large areas of our shallow fresh waters are suitable for growing such crops of the water calthrops and several species of lotus. The peanut, as a nut-bearing annual plant, is being cultivated successfully over an increasingly large area in different countries, and promises to furnish a permanently valuable food-supply.

The nuts of trees and shrubs which are to be planted require treatment somewhat different from that of other seeds. In nature they are prone to await suitable conditions of warmth and moisture which are quite out of the ordinary, before sprouting. In temperate regions the most successful method, perhaps, consists of storing them for the winter in cages made of galvanized wire about 8 inches deep, sunk about 4 inches beneath the surface of the ground, and the interior of the cages filled with sand to the ground-level. Nuts which are to be grown in the following season are pressed into this sand in rows, closely together but not wholly covered with sand. A loose mulch of leaves is tossed over them and the wire cover of the cage closed in order to protect them against rodents. These nuts are allowed to freeze and thaw during the winter and spring. In the spring the mulch is removed, allowing the exposed side of each nut to be warmed by the sun while the buried part is kept moist. Under such conditions almost every nut of species belonging to temperate regions will sprout. As rapidly as the nuts sprout, they are transferred to the nursery row and cultivated for two or three years before being transferred to permanent sites as seedlings or as grafted stocks.

For illustrations of methods of budding nut-trees, see page 1366, Volume III; also the article *Pecan*.

Robert T. Morris.

Culture of the different kinds of nuts.

From the earliest times, nuts have been used as an article of food in North America. The prehistoric tribes left evidences of their use in the specimens which were buried with their remains. When the white settlers came, they found several kinds of nuts growing wild and bearing abundantly, and thought to introduce the cultivated nuts of Europe along with fruits and farm crops that seemed to flourish in the virgin soil. But little success seemed to attend their early effort, largely because of the unsuitability of the varieties tested. The sweet almond and the hazels were found to be of this character, and the few experiments with the European walnut and chestnut, where they did succeed, were not followed up by extensive plantings for many years. Nor were any of the native nuts brought under cultivation until very recently. Now there are many orchards and groves of both foreign and native nuts, some of which are already yielding profitable crops.

The almond (*Prunus Amygdalus*).

Among the first nuts to be tested were the cultivated almonds. All the experiments up to the present day lead to the conclusion that the choice varieties are not suited to any section east of the Rocky Mountains, except, perhaps, in southwestern Texas and New Mexico. The close relationship to the peach would cause us to expect that it would succeed wherever that fruit does; but the trees of the choice varieties are too tender to endure any but very mild climates, and the fruit-buds are still more tender. The chief failing, however, is the habit of very early blooming, which causes the crop to be cut off by spring frosts, except in peculiarly favorable localities. There are differences in the ability of the varieties to endure cold, and in time of blooming, even where they are counted a success. Not until seedlings were grown and tested, from which selections were made of suitable kinds, did the growing of this nut prove profitable.

At the present time the culture of the almond is confined chiefly to California. To some extent it is grown in Utah, Idaho, Arizona and New Mexico, and fair crops of the highest quality in all respects are grown there. There are single orchards in California of hundreds of acres in extent. The average crop of the region is estimated to be about 3,000 tons or 6,000,000 pounds, and in view of the large quantities of almonds imported there is room for a large increase in production. This is being met to a considerable extent by extensive plantings in California. It is thought that the production of new seedlings will still further overcome the weak points already mentioned, and materially extend the culture of really choice varieties to some extent. The varieties being grown are nearly all of California origin and are Nonpareil, I X L, and Ne Plus Ultra, and are esteemed for market in the order named. Drake, Texas Prolific and Languedoc are also prized, especially for shelling, but their price is not equal to that of the others named. The methods of planting and cultivation of the soil are about the same as for the peach. Twenty to twenty-five feet is a good distance apart for planting the trees in rich soil; sometimes they are set as much as thirty feet apart. In the state of California, they are frequently set in the quincunx form. See also *Almond*, Volume I.

The walnuts.

American walnuts.—The kernels of all species of the walnut family are liked because of their rich and delicious flavor; but some of them are so small and difficult to get out of the shell that they are of little or no commercial value. Our native black walnut, *Juglans nigra*, and butternut, *J. cinerea*, are of this character. At present there are very few trees of either species that are grown for their nuts; but there are some prospects of improvement in this direction.

Asiatic species.—Within the last forty years there have been introduced from Japan two new walnuts, *J. Sieboldiana* and var. *cordiformis*, and from Manchuria one, *J. mandshurica*. These make beautiful and stately trees, but the nuts of all but *J. Sieboldiana* var. *cordiformis* have too thick shells to be of much value. See *Juglans*.

Persian species.—The Persian walnut, *J. regia*, which has long been called English walnut and by several other titles, has been cultivated for many centuries for its thin-shelled and richly-flavored nuts. It is a native of Persia and the regions about the Caspian Sea. The Greeks and Romans took it to southern Europe before the Christian era. It was brought to America in the early settlement of the country, but did not succeed everywhere, and the few trees that survive in the eastern states have been mostly neglected. Some of them have borne nuts abundantly and others have not. Unproductiveness has generally been due to the isolation of the trees and the inopportune times of the blooming of the flowers of the two sexes. These isolated trees are scattered over the eastern states from New York to Georgia, and rarely beyond the Appalachian mountain chain, because of the more uncongenial climate there.

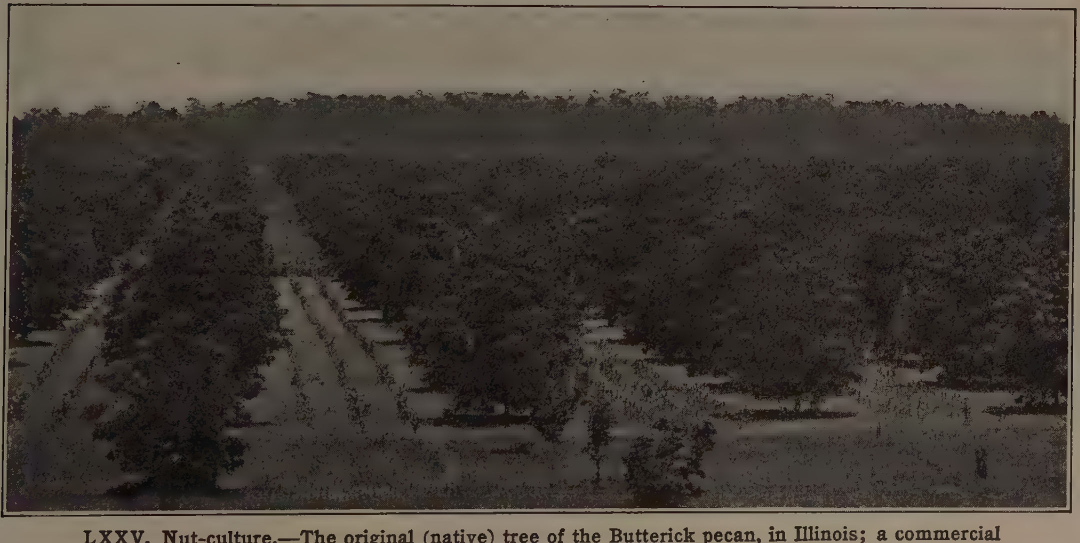
Regions of successful culture.—On the Pacific coast the Persian walnut is a great success, especially in southern California. True enough, there are some failures, but they are mostly due to lack of proper pollination, a matter which can and will soon be generally understood and overcome. There are extensive orchards already in bearing, and with the advantages which are now being afforded by the introduction of the best varieties from Europe and the origination of improved seedlings, the walnut industry is sure to advance rapidly in that region. The soil of the richer valleys of the Pacific slope is just what is needed, and where there is an abundant supply of water a few feet under the surface there is no need of irrigation. But in poor, dry soil it is folly to expect success. The crop of California alone, in 1910 was about 10,000 tons or 20,000,000 pounds, or 1,000 carloads of 20,000 pounds each. It is confidently expected that California alone will, within a few years, produce all that our home markets require. Recently a very deep interest has developed in walnut-culture in the Atlantic States, as some of the hardiest and most fruitful seedling trees have come to be appreciated, are given varietal names and are being propagated by the nurseries. As yet there are very few trees planted out in orchard form, but there are a few small orchards of such trees, mostly in New York, New Jersey and Pennsylvania, and there are larger ones of seedlings of these improved strains, some of which are in profitable bearing. There seems to be good reason for believing there will be a thriving industry in walnut-culture in the Atlantic States and possibly farther to the westward within a few years to come. But the experiments with *J. regia* have not been very favorable to it in the central or Mississippi Valley regions west of the Appalachian Mountain chain, perhaps owing to the changeableness of the climate.

Propagation.—The larger number of bearing trees are seedlings, but those grafted or budded with choice varieties are far preferable, and such trees will form the walnut orchards of the future. The native black walnut, *J. nigra*, is the species used as a stock principally in the eastern states and it serves the purpose very well. *J. rupestris*, a species native in Texas and adjacent regions, is also used as a stock, especially in the South, and the varieties of *J. regia* grow very well on it. This native species is closely allied to *J. californica*, which is now used in California, Oregon and Washington as a walnut stock more than any other species. *J. cinerea* is being tested in a small way for this purpose, and so are the Asiatic species, but so far with uncertain results. The planting of seedling walnut orchards is giving way to those of the named varieties, of which there are many and among them several that have proved to be reliable bearers and their nuts of standard commercial value. Although some seedlings are grown and sold by the nurseries, they are becoming unpopular. There are a few small nurseries both East and West now devoted almost entirely to the growing of grafted and budded walnut trees.

Planting and culture.—The distance for the trees to stand apart in the orchard is from 40 to 60 feet, according to the vigor of the variety and the richness of the soil. Clean tillage is best for the trees until they reach bearing age, when the ground may be seeded to some grass that does not make a compact sod. If hoed crops are grown between the trees until that time, it will do no harm and economize the space. Almost no pruning is needed for this tree, except to keep the branches from getting so low as to interfere with tillage. The trunk should be 4 to 5 feet high. See *Walnut*, Volume VI.

The chestnuts.

American species.—Like the walnuts, our native chestnuts are not so desirable for market purposes as those from foreign countries. The wild American chestnut, *Castanea dentata*, is richer in quality than any foreign kind, but the size is less than half that of the introduced nuts. Throughout the larger part of the eastern United States, and extending into lower Canada, there are untold millions of native chestnut trees, yielding a wealth of nuts that find ready sale in the markets, so far as they are gathered; but the prices are only about half those of the large cultivated and imported product. At the present time there are but



LXXV. Nut-culture.—The original (native) tree of the Butterick pecan, in Illinois; a commercial pecan plantation in Georgia.

few attempts made to cultivate this species. Some of the choice varieties with the largest nuts are being collected for experiment, and there is reasonable prospect that by hybridization and selection of seedlings varieties may yet be secured combining the vigor and hardihood of the wild trees with the characteristic natural sweetness and large size of the foreign nuts. Within the last few years, there has been developed at least one very choice variety of our native species that is surpassing in general desirability to all others, either native or foreign. This is an accidental seedling that originated from among a lot of nuts planted by Charles A. Green in his nursery near Rochester, New York. It was sent to E. A. Riehl, of Alton, Illinois, and it grew vigorously and when it came to bear, to his surprise the nuts were very much larger than those of the average of the American species, although possessing the natural outward appearance and sweetness of kernel that are characteristic. This variety was named the Rochester. The nuts nearly all ripen at one time and part from the burs easily. Some of its seedlings are said even to surpass the parent.

The chinquapin, *C. pumila,* is the smallest of the chestnut family, in size of both nut and tree. Rarely is it anything more than a mere bush. It has rarely been cultivated, although the bushes are productive, the nuts of good quality and ripen very early.

European species.—The Old World chestnut, *C. sativa,* has been under cultivation almost as long as history goes. It was brought to America in the first century of its settlement by Europeans; but not until within the last twenty-five years has there been more than an occasional tree found on our shores. The accidental finding of a chance seedling, which was finally named Paragon and sent out to the public about 1887, and the bringing to notice of the Ridgeley shortly before that time, were the means of exciting the first general interest in chestnut-culture in America. Both these kinds, and a great many more named varieties, are now being propagated and scattered far and wide. They are all of large size but not so sweet as our native chestnuts, and generally have bitter skins. The trees are of robust character and very productive, but more tender than our natives.

Japanese species.—About the time that the European species was becoming popular in America, attention was drawn to a number of seedlings from nuts that had been brought from Japan during several previous years. The most of them were larger than any that had been known before, either in this country or in Europe. Many of them are now named and widely distributed. Some of the smaller varieties are exceedingly early in ripening. Nearly all of them begin to bear at an early age and are even more productive than the average of the European species. In quality, the nuts of most of them are not so sweet as the European kinds. The habit of growth is less vigorous than that of other chestnuts and the foliage much smaller.

From these two foreign species have been obtained nearly all of our varieties that up to this time are worthy of general cultivation, except the Rochester. They vary from seed much as do most other improved varieties of fruits, and grafting and budding must be practised, which are exceedingly difficult successfully to perform on the chestnut, as is the case with all other nut-trees. They will both unite fairly well with our native stocks; although sometimes the union is imperfect and the top breaks off.

Grafting.—The most successful method of propagating nut-trees, so far as the writer has experimented or learned otherwise, is late bark-grafting. This requires that the cions be cut before there is any possibility of the buds starting, and put in some very cool place until after the stocks have begun to leaf out. The stocks are then cut off as for cleft-grafting, but the bark only is split with a knife for an inch or more at the top of the stock. The cion is trimmed to a long wedge, all from one side. The point of this wedge is introduced under the bark at the top of the slit and gently forced down until the cut surface of the cion is even with the top of the stump. It is then tied fast with a string and the wound securely waxed. Large trees may thus be top-worked in their branches with considerable success. Small stocks should be grafted just under the surface of the ground and banked nearly to the top of the cion.

Stump groves.—In several cases, large tracts of chestnut stump lands have been grafted over to the improved varieties of the foreign species with good success. All other trees should be cleared away and only two or three of the strongest sprouts left on each stump. These should all be grafted and allowed to grow until it is sure that there will be a sufficient stand, when those that are not needed should be cut away. In future years more may be cut away to give the remaining trees ample room.

Chestnut orchards.—The best results are said to be attained in chestnut-culture by planting grafted trees on open land, about 40 feet apart and in regular orchard form. This plan admits of giving the trees good tillage until they have attained large size, when grass may be sown and stock allowed to graze it, except when the nuts are falling. Such orchards are said, by those who have tried them in comparison with grafted sprouts, to yield more than twice as much to the acre. Well-drained sandy or shaley lands are the best for the chestnut.

Pests.—A fatal fungous disease has become very prevalent within recent years in the eastern United States. It began on the North Atlantic coast and has gradually moved southwestward until there is scarcely a locality north of southern New Jersey and Pennsylvania where it is not prevalent. In some places the cultivated and wild chestnut trees have been practically exterminated. There seems to be no practicable means of combating this disease, and it is feared that the entire area in the eastern states where the chestnut is found will be reached by it and may be ravaged. Another enemy of chestnut-culture is the weevil. In some cases the nuts are so badly infested that they are practically worthless. The eggs from which the larvæ develop are laid by long-snouted beetles while the nuts are growing, and by the time they are mature most of the eggs are either hatched or nearly ready to hatch. By treating the nuts with the fumes of bisulfide of carbon the eggs or larvæ can all be destroyed. Scalding with boiling water for about ten minutes will also kill them, but it also destroys the germinative power of the nuts and necessitates drying them. Outside the native chestnut area, there are no weevils as yet. See *Castanea* and *Chestnut.*

The pecan (Carya Pecan).

In the wild state.—Of all our native nuts the pecan is the best. Its natural habitat is the lower Mississippi basin, from Iowa to the Gulf coast, but it will grow equally well in any climate and soil of approximately the same character. The tree is almost as hardy as any of the other hickories, except some of its more southern varieties. In size the tree varies from medium, on land of ordinary fertility, to gigantic proportions on the rich river and creek bottoms. The nuts vary in size and shape from round and ½inch in diameter to oblong and 2 inches in length. The kernels are exceedingly rich and sweet, and the shells usually thin. Pecans are found in all confectionaries, and bring almost as high prices as any of the imported nuts. The largest quantities of native nuts are secured from Texas and Louisiana. Millions of pounds are gathered annually in those states and sold to dealers, thus bringing a handsome revenue to many persons of moderate means.

Under cultivation.—The decrease of the wild product from the cutting down of the trees, and the better prices obtained from large, thin-shelled nuts have induced the planting of pecan orchards. The nuts sprout readily, and the trees are of easy growth, with reasonable care, in proper soil and climate. Orchards of 10 to 1,000 acres are planted in the southern states. There are many smaller orchards planted in nearly all the states from Virginia to Missouri and California, southward. The line of 40° north latitude is about the limit of successful pecan-culture, and the region from 35° southward is much better. The nuts do not fill and ripen well where the growing season is short. It has been learned that by cutting back the tops of wild trees (thus causing an abundance of sprouts), and then budding in August or September, large trees may be quickly transformed into such as will produce the highest grade of nuts.

Planning the orchard.—There is a division of opinion as to the advisability of planting the nuts where the trees are to stand and rearing them for a year or more in a nursery. Both ways are good, but each has its advantages. If the former of these plans is followed, then two or three nuts should be planted where each tree is to stand and a cedar or cypress stake driven at the spot. Pine stakes are said to induce worms to attack the little pecan trees. A still safer plan is to inclose the little seedlings in narrow boxes about a foot high, made of cypress boards. This secures them from the depredations of rabbits, which sometimes prove very destructive. By this plan there is no labor or danger of loss by transplanting. All but one of the trees should be removed after two or three years' growth. If the nursery method is followed, the transplanting should be done at one of these ages. Mulching the trees with old trash is very beneficial to them.

2538. Coconut, the most important of tropical nuts.

Propagation.—Grafted or budded trees are far preferable to seedlings, because of the certainty of the variety, convenience of gathering the nuts at one time, and the advantage of having an even and high grade to sell. The same difficulty is met with as in case of the chestnut—the trouble and expense of securing grafted or budded trees. However, it has been found that both these methods of propagation are reasonably successful in skilful hands. Either the cleft-, tongue- or bark-graft will succeed, but the two former styles do better on small stocks just below the surface of the soil than above. Probably the most universally successful method of propagating the pecan is that of the bark-graft, although experienced nurserymen more largely employ the patch-bud. Trees with unions a foot or more above ground are much less subject to winter injury than are root-grafted trees.

Planting and cultivation.—The distance for planting should not be less than 50 feet between trees, because they get to be very large, and 80 to 100 feet is better. Thorough tillage will pay abundantly and should never be neglected while the trees are young. Farm crops, such as corn, cotton and potatoes, may be grown between the trees until they begin bearing, which is from 6 to 12 years from planting.

Varieties.—There have been wonderful developments in the discovery and production of choice varieties of the pecan within the last twenty-five years, and especially within the last decade. The first variety to become popular and one which is now held in high esteem is the Stuart. It originated from a nut planted on the coast of Mississippi and was brought before the public by the late W. R. Stuart of Ocean Springs, Mississippi, after whom it was named. The next one of note to be brought forward was the Van Deman, which originated from a nut planted in St. James Parish, Louisiana, near the bank of the Mississippi River fully fifty years ago. The tree is yet in full vigor and bearing abundantly. These two varieties have been the parents of thousands of seedlings, some of which have become famous already and others are constantly coming forward, even of the second and third generations. Among the principal varieties now being grown in the South, are the Alley, Bradley, Colorado, Curtis, Delmas, Frotscher, Halbert, Kincaid, Moneymaker, Pabst, President, San Saba, Schley, Sovereign, Stuart, Success, Taylor, and Van Deman. The best of the northern varieties are the Busseron, Butterick, Greenriver, Indiana, Major, Niblack, Norton, Posey, and Warrick. With the exception of the Norton, which originated in eastern Missouri, the varieties of this latter group are from the vicinity of Evansville and Vincennes. See *Carya* and *Pecan.*

The coconut (Fig. 2538).

There is comparatively little territory on the continent of North America where the coconut will grow; viz., a small portion of Florida and the warmer coast regions of Mexico. In the warmer parts of California the climate does not seem to be sufficiently humid. In the vicinity of Lake Worth, and Biscayne Bay, Florida, there are many bearing trees, and along the east coast and adjacent islands from there to Key West, and as far north on the west coast as Charlotte Harbor, there are many thousands of coconut trees growing. In central Florida the climate does not seem to be suitable. Proximity to the sea in all countries seems to suit the coconut best. It will flourish in almost any soil, although the richer the better, but a warm and humid atmosphere is indispensable.

Origin of coconut-growing in America.—The oldest coconut trees in Florida were probably chance seedlings which came from nuts that washed ashore from the sea long years ago. Such trees are very rarely found. There are also a few old trees that grew from nuts planted by settlers at Key West and other places along the coast. The chief cause of the impetus to coconut-growing was the wrecking of the Spanish bark Providencia, laden with coconuts, on the beach near Lake Worth, Florida, January 9, 1878. Many thousands of the nuts were gathered from the surf and planted for many miles up and down the coast. The trees grew so rapidly and began to bear so soon, usually at from six to eight years from seed, that visions of wealth tempted many more into planting groves. One near Biscayne Bay consisted of about 4,000 acres, in which were 300,000 trees. Another at Cape Sable contained 42,000 trees, and there are many more of less extent.

Present status.—Cold waves and occasional frosts have injured many of the coconut trees, in some cases killing them outright. In general, the trees bear good nuts in reasonable quantity, but in a business way the industry is uncertain, owing to danger from frosts and the cheapness of imported nuts. As an interesting novelty, the coconut in southern Florida is an eminent success. See *Coconut.*

Nut-culture in New Mexico. (C. P. Wilson.)

In the newer parts of the country to which commercial nut-growing is adapted, the development of this industry will be coincident with that of the country itself rather than an addition in after years. As an indication of the outlook on nut-culture in new regions, this note is inserted on the industry in New Mexico; and what is said of this state will undoubtedly apply very well to Arizona and adjacent regions.

Much attention has not been given, so far, to nut-culture in this state, though a few small experimental orchards of pecans, as well as a number of almond and Persian (English) walnut trees, have been set out. Most of these are in the irrigated valleys of the southern part of the state. The climate of this state is well suited for the heavy fruiting of pecan trees that have originated near the western limit of the region to which this species is indigenous. Many of the large seedling trees to be found in different parts of New Mexico are very prolific. However, most of the early attempts to transplant either the seedling trees or those that had been budded or grafted were unsuccessful. This appears to have been due largely to the fact that sufficient precautions were not taken to prevent the young trees from dying back during the dry winters that usually prevail in this part of the Southwest. Attempts along this line during the past few years have been more successful, and it is believed that, by keeping the ground very moist during the winter, much of the damage can be prevented. Hilling up the soil around the trees of some varieties the first few winters after transplanting would also, no doubt, be advisable, as an additional protection. It is doubtful whether the pecan will do well where there is much alkali, or where the water-table is within 8 or 9 feet of the surface. Growth will probably be better on land that has been cultivated for several years than on new ground. Varieties suitable for southern New Mexico are the Sovereign (Texas Prolific), Hollis, and Halbert; while for the northern part of the state, sorts that originated farther north, such as the Indiana, Kentucky, and Warrick, might do better. Coast varieties and southern varieties that originated east of Texas are not recommended at present for any section of the state, though some of these might do fairly well. It is probably better to transplant the budded or grafted trees, rather than to grow the seedlings with the idea of topworking them later. While the pecan can be budded in this climate, the operation has to be conducted carefully if success is to be expected.

It is quite possible, or even probable, that varieties of Persian walnuts will, in time, be found that will grow well in this state. The climate of New Mexico is not so well suited to the Persian walnut as to the pecan. The leaves of the former are inclined to sunburn during the summer, and some injury may occur to the young growth during the winter or early spring. There are at present a few trees in the southern half of the state that are in bearing. Some of the nuts are of good size, but no data are available concerning the yield.

The early blooming habit of the tree prevents the production of almonds on a larger scale. However, recent experiments have proved that a few of the commercial varieties of almonds are little, if any, earlier in this respect than the Elberta peach; though most of the almonds bloom entirely too early to be of any importance in this region. The tree grows well in the irrigated valleys.

There seems to be no record of experiments having been conducted with chestnuts, but on account of the fact that New Mexico soils, on the whole, are rich in lime, this tree would probably not do well. It is also doubtful whether filberts could be grown successfully in this climate.

Literature.

There are several American publications devoted exclusively to nuts: Stewart, H. L., "The Pecan and How to Grow It," 1893; "Nut Culture in the United States," 1896, being a bulletin of the Division of Pomology, United States Department of Agriculture; Fuller, "The Nut Culturist," 1896; Lelong, "California Walnut Industry," 1896; Parry, "Nuts for Profit," 1897; Risien, "Pecan-Culture for Western Texas," 1904; Hume, "The Pecan and its Culture," 1906; Wight, "Pecans," 1906; Price, E. M., "The Walnut," 1910; Allen, W. F., "English Walnuts," 1912.

An important part of the current literature of nut-culture is contained in the reports of special societies. The National Nut-Growers' Association issues publications: see page 1554, Volume III. The Northern Nut-Growers' Association issued the Report of its Third Annual Meeting in 1912, comprising a publication of 140 pages; secretary and treasurer, Georgetown, Conn. There are also journals devoted wholly or in considerable part to nut-culture: See periodical list, pages 1560, 1561, Volume III.

H. E. Van Deman.

NUTMEG: *Myristica.*

NUTS. In popular usage a nut is a hard vegetable product, usually a fruit, inclosing an edible part within a shell; and the edible kernel or meat is released by breaking the integument. Technically or botanically, a nut is a hard and indehiscent one-seeded pericarp arising from a compound ovary; but it is hardly to be expected that this very special use can prevail as against the long-established popular usage. In this article, the word nut is understood in its popular or usual application; it may be difficult to define, but it is readily understood.

The purpose of this catalogue, by C. A. Reed, is to name and describe all the nuts that are likely to be found in commerce in this country or which may be subjects of rather common inquiry. Not all of these nuts are grown or cultivated in this country and therefore some of the genera may not be found elsewhere in the Cyclopedia; that is to say, this is not a cultural article but only descriptive and is independent of any alphabetical entries elsewhere in the work. For the cultivation of nuts as practised in North America, see the article *Nut-culture.*

L. H. B.

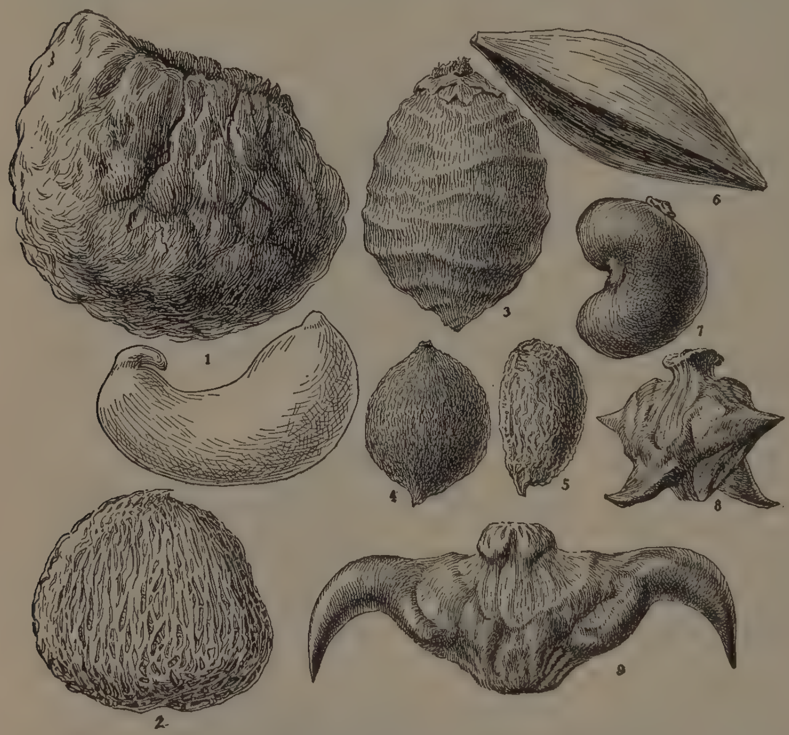
Æsculus Hippocastanum. Horse-Chestnut. *Hippocastanaceæ.* Inedible seeds, about equal in size to the largest of the European chestnuts, but less regular in form and having a somewhat stronger and more shining shell. Borne in a one- to three-celled prickly pod. The fruit of an ornamental tree familiar in the North Temperate Zone, of both the Old World and the New.

Aleurites spp. Wood-oil Nuts of China and Japan. Lumbang of the Philippines. Candle-Nut of the tropics. Tahiti, Spanish, or Country Walnut. *Euphorbiaceæ.* Irregularly rounded to spheroidal nuts, from 1 to 2 inches in diameter, ranging in color from mottled gray to nearly black, and having a hard but brittle shell, about ⅛ inch in thickness. Borne in fruits, 2 or 3 inches in diameter, containing about five nuts each. From the kernels of these nuts, which are considered edible only from certain species, and when half-ripe and roasted, there is obtained a valuable oil, known as country walnut oil, artists' oil, kekune (Ceylon), or kukui (Sandwich Islands) oil. Used medicinally, this oil has strong purgative properties; more largely, it is used in paints and varnishes, where it is said to have a very quick-drying and hardening effect. The cake which remains after the oil has been expressed is used as a cattle-food and as a fertilizer. To a large extent, the nuts are strung on the fibers of a palm leaf and used as an illuminant by the natives where the species are grown.

The genus is native to the milder parts of the North Temperate, and the northern portion of the Tropical Zone of the Orient. The Office of Foreign Seed and Plant Introduction has introduced the wood-oil trees into the southern states and California, where their culture promises to become an important industry.

The following list includes the more important species and several of the common names by which the fruits are known: *A. Fordii*, Chinese wood-oil nut, tung yu; *A. molluccana* (*A. triloba*), candlenut, Spanish walnut, Tahiti, or country walnut, kukui of Hawaii; *A. montana*, Mu-yu wood-oil.

Anacardium occidentale. CASHEW. CACHEW. ACAJOU. CAJA. CAJOU. MONKEY-NUT. *Anacardiaceæ*. Kidney-shaped nuts, an inch or more long, by about ⅞inch wide and more than ½inch in thickness, with a double outer shell, between which is an oily, dark brownish fluid, very acrid and possessing extremely poisonous properties similar to those of poisons ivy and sumac, to which the species is closely related. The outer shell is smooth and ivory-like in appearance, rigid and tough but thin and easily cut. The kernels are firm, sweet, and very agreeable when roasted. The nuts are formed on the end of a fleshy pear-shaped pedicel. Figs. 33, 192, Vol. I.



2539. *1*, Caryocar, husk above, nut below; *2*, Telfairia; *3*, Betel-nut, Areca; *4*, Gevuina; *5*, Pistacia; *6*, Pili-nut, Canarium; *7*, Semecarpus; *8*, Trapa natans; *9*, Trapa bispinosa. (×⅜)

Cashew-nuts do not appear in the market until after the poisonous properties have been entirely dispelled by roasting and the wholesome kernels have been separated from the shells. The species is native to the West Indies. It is now cultivated to a very large extent throughout the American tropics, both north and south of the equator.

Apios tuberosa. GROUNDNUT. WILD BEAN. *Leguminosæ*. The numerous, dark brown, fleshy tubers from 1 to 2 inches in length, by 1 to 1½ inches in diameter, and of somewhat irregular, oval or rounded form, which are borne on the rootstocks of an elegant twining perennial. Little use is made of these tubers, although they are said to have a rich nutty flavor when properly prepared. The species is native to lowlands of the eastern part of the United States, from Pennsylvania on the north, to Georgia on the south. Fig. 233.

Arachis hypogæa. PEANUT. GOOBER. PINDAR. GROUNDNUT. GROUND PEA. MANILA-NUT. MONKEY-NUT. *Leguminosæ*. Familiar straw-colored, oblong nuts, with thin fibrous, papery shells, rounded at the ends, and constricted at the middle, common at all fruit-stands. They are the seeds of a low-growing annual which pushes its pods under ground while they are maturing. Extensively cultivated in the southern part of the United States and elsewhere that seasons permit.

The constriction at the middle forms a partition between the two end chambers, each of which contains a single nutritious kernel. These are most commonly eaten when roasted, although to a large extent they are used when raw or boiled. The nuts are very rich in a valuable oil, useful in cooking and in the making of salads.

Areca Catechu. BETEL-NUT. ARECA-NUT. PINANG. *Palmaceæ*. Fig. 2539. The seed of an eastern tropical palm, which in size, general character and color much resembles the ordinary nutmeg. In form the "nuts" are not unlike the acorns of white oak, except that they are more rounded at the apex. To an enormous extent, betel-nuts are dipped in lime, wrapped in betel leaves (Piper betle) and chewed by the natives of the tropics, especially of India and the Philippines. The effect of betel-chewing is much the same as that of tobacco-chewing in this country. Fig. 367.

Attalea Cohune. COHUNE-NUT. CAHOUN-NUT. *Palmaceæ*. The oval or fusiform seeds of the cohune palm of Central America. Typical specimens measure from 2 to 2½ inches in length, by about 1½ inches in greatest diameter. Within the shell, which is fully ⅛ inch in diameter and very hard, is a single elliptical kernel. Cohune-nut oil has long been used in the manufacture of soap and as an adulterant for coconut oil. At present "There is practically an unlimited demand for all of these (palm) oils in the European margarin trade, where they are now preferred to oleo oil and neutral lard as a hardening ingredient."—"Daily Consular and Trade Reports," June 27,1914.

Attalea funifera. COQUILLA-NUT. *Palmaceæ*. Seeds of a rich brown color, 3 or 4 inches long, oval and of very hard texture. Used as a substitute for ivory in the manufacture of door-knobs, umbrella handles, buttons and various other commodities of the household. From a lofty South American palm. Fruits borne in large clusters.

Bassia latifolia (*Madhuca indica*). ILLIPE- or ILLUPE-NUT. *Sapotaceæ*. The long-oval, smooth-surfaced, coffee-colored seed of a tree native to the East Indies. Typical seeds measure approximately 1½ inches in length by ½ inch in diameter. According to the "Daily Consular and Trade Reports," "Illipe-nuts are used to manufacture an edible oil similar to lard." This report further says: "There are two crops a year, one large and one small. The large crop is now (August 12) nearly finished and a new crop will come in from March to June, 1912."

Bertholletia excelsa. BRAZILNUT. BUTTERNUT. NIGGER-TOE. CREAM-NUT. PARA-NUT. CASTANEA or CASTANA (corruption of "Castanha," Portuguese word for chestnut). JUVIA-NUT. *Myrtaceæ*. The seeds of certain very large, uncultivated trees, common to great areas of the river-bottom sections of northern Brazil. Grown in a spherical or pear-shaped capsule of 2½ or 3 inches in diameter, having a hard, woody, outer wall, within which are encased from eighteen to twenty-four of the nuts. The capsule is covered with a dark brown outer husk greatly resembling that of the walnut.

The nuts which are sharply triangular, measure from 1½ to 2 or more inches in length, by ½ to 1 inch in greatest diameter. They have a single, solid kernel, sweet and very good, which is protected by a somewhat rough, rigid but thin shell, to which it often closely adheres. Fig. 543.

Received into this country for consumption in enormous quantities during the months of spring and early summer, and held in storage until the following season.

Brosimum Alicastrum (*Piratinera Alicastrum*). BREAD-NUT of Jamaica. *Moraceæ*. The small roundish, yellow or brownish seeds, an inch or less in diameter, of a large tropical American tree. These seeds are borne singly or sometimes two in a thin paper-like, but stout shell, with smooth and somewhat granular surface. They are edible only after cooking or roasting.

Bunium Bulbocastanum. LOUSY-NUT. EARTH-NUT. EARTH-CHESTNUT. HAWK-NUT. KIPPER-NUT. PIG-NUT. AR-NUTS. YER-NUTS. JUR-NUTS. *Umbelliferæ*. Small nut-like tubers which form on the roots of plants of this species. They have a sweetish taste and are eaten by children, either raw or roasted. Rather too acid for adults unless roasted. From western Europe.

Butyrospermum Parkii. SHEA-NUT. *Sapotaceæ*. The shea-nut is the seed of an extensive African tree (butter tree) which according to Consul W. J. Yerby, "Daily Consular and Trade Reports," in Sierra Leone, British Africa, grows to a height of over 40 feet. "The nut," he says, "is of about the size and shape of a walnut, but is covered with a smooth skin resembling that of a Spanish chestnut, which can be pulled off in the same way when fresh. Inside this skin is a soft kernel of a light yellow color when fresh, and chocolate color when dry, which contains a large proportion of fatty material, that when extracted is called shea butter.

"The outside fleshy pulp, whose weight is approximately equal to that of the nut, rots away in time and splits, leaving the nut exposed. The natives hasten its removal by burying the freshly gathered fruit in a pit for some days. The nuts, divested of their outer covering (pulp), are dried, either by being placed in the sun for about twelve days or by heating in an earth oven. In this process the nut loses 30 to 40 per cent of its weight. The skin is removed and the kernel remains. The shea-butter content of the decorticated kernel is 40 to 60 per cent of this weight of the kernel."

Regarding this butter, Yerby continues that "Purified shea-butter is edible and suitable for use in the preparation of artificial butter by chocolate manufacturers, etc., and the principal European demand will be for this purpose."

Shea-butter is used in the making of certain soaps but according to Yerby, "The high percentage of free fatty acids renders shea-butter unsuitable as a lubricant."

Calodendrum capensis (*Pallasia capensis*). Cape Chestnut. Wild Chestnut. *Rutaceæ.* The shining black, irregularly rounded, and somewhat wedge-shaped, seed of a subtropical tree of southern Africa, of about ¾inch in length. These seeds have a stout but thin shell and a single farinaceous kernel, which resembles somewhat the texture of a chestnut. Cultivated mainly as an ornamental.

Canarium luzonicum. Pili (Pee-Lee)-Nut. Philippine-Nut. Luzon-Nut. Java Almond. Phillo-Nut. *Burseraceæ.* Fig. 2539. The smooth, hard-shelled, triangular seed of a tree native to the Philippine and other Pacific Islands of the far East, which has recently become very common in the American markets, sometimes separate, but more often in "mixed" nuts. The natural color of these nuts is a light brown, varying somewhat on different parts of the nut. As oftenest seen in the market, it is of a uniform reddish color, given it by an artificial dye, which may readily be detected with a moistened finger.

These nuts are inclined to be slender, sometimes attaining a length of 2½ inches and a middle diameter of but ¾ to ⅞ of an inch, though sometimes they are short and blunt-pointed with about the same diameter. Typical specimens taper gracefully from near the middle into long, sharp-pointed ends. Inside the shells, which are exceedingly difficult to crack, are single kernels said to be of excellent quality in good specimens, but which as commonly appear in our markets are well below that of most other nuts.

The use to which pili-nuts are most commonly put is that of food, but it is said that to a more or less important extent, they are used in the manufacture of certain kinds of baby foods, emulsions, and the like.

Carya spp. Hickory-Nuts. *Juglandaceæ.* The seeds of one of the most important groups of American trees, representative species of which are indigenous to nearly every section of the central, eastern and southeastern parts of the United States. With the exception of a few which are very astringent, the nuts of all species are edible; some being among the choicest nuts of the market. Of the better known species, with the exception of the nuts of the pecan (*Carya Pecan*) and of the water-hickory, or bitter pecan (*C. aquatica*), hickory-nuts as a rule are inclined to be globular in form, sometimes of smooth surface, or with but faint ridges, but very often with sharp ridges and therefore distinctly angular. The color range of hickory-nuts includes almost white, creamy white, and light or dark brown, with gradations between. The shells vary in thickness from extreme paper-like thinness, characteristic of certain varieties of pecans, to extreme thickness and hardness, common with the mocker-, or bull-nut (*C. alba*). The kernels are formed in two distinct halves or cotyledons, separated from each other by a partition which may be thick, thin or papery, hard or corky, or a variation of any of these.

The following list includes the names of the more important species and their common names: *C. alba*, mocker-nut, bull-nut, big-bud hickory; *C. aquatica*, water-hickory, bitter pecan; *C. cordiformis*, bitter-nut, swamp-hickory; *C. glabra*, pig-nut; *C. lacinosa*, big shellbark, bottom shellbark, big shagbark, scalybark, king-nut, white walnut; *C. myristicæformis*, nutmeg-hickory; *C. ovalis*, small pignut, false shagbark; *C. ovata*, shagbark, little shagbark, little shellbark, little scalybark, white walnut, walnut, tuscatine; *C. Pecan*, pecan, Illinois-nut. Figs. 823–831; 1836–7.

Caryocar spp. Peruvian Almond. *Caryocaraceæ.* Fig. 2539. A nut, in many respects resembling the chestnut, from at least certain districts in Peru and western Brazil, which has probably not yet appeared in this country except in botanical collections. The kernel, which is about equal in size to that of the Brazil-nut, is borne singly in a bur resembling that of a rather small chestnut bur with very short spines, is somewhat kidney-shaped, and has a handsome rich brown color. In fineness of texture and in richness of flavor, this nut is said to excel any other nut of the tropics. It is most highly prized by the natives. Messrs. Bennett, Day & Company, importers in New York, now contemplate the making of inaugural shipments into this country during the coming season (1915–16).

There are said to be at least ten species of Caryocar. Of these, two from Guiana, both of which are called Guiana butternuts, are *Caryocar butyrosum*, pekea-nut, and *C. nuciferum*, souari or butternut.

Castanea spp. Chestnut. *Fagaceæ.* Reddish brown, irregularly obovate, or obconic nuts, ranging in size from ¼ to 2 inches in greatest thickness, having thin papery shells, and being borne in stiff brown burs, thickly covered with stiff, short or long, single or compound, sharp spines. The fruits of an important genus, well known in many parts of the North Temperate Zone in both the Old World and the New. Kernels of the small American and Chinese chestnuts, and of the small chinquapins, are of excellent flavor; average European chestnuts are of fairly good flavor, by comparison, while the Japanese chestnuts are usually of very inferior quality, except when boiled, roasted, or otherwise prepared.

The names of the principal species bearing nuts of importance are as follows: *C. alnifolia*, creeping chestnut, southeastern United States; *C. crenata*, Japan chestnut, Japan; *C. dentata*, American chestnut, northeastern United States; *C. mollissima*, Chinese chestnut, China and Korea; *C. pumila*, chinquapin or dwarf chestnut, eastern and central United States; *C. sativa*, European, French, Spanish or Italian chestnut, Europe. Figs. 833–835; 911–917.

Castanospermum australe. Moreton Bay Chestnut. Australian Chestnut. *Leguminosæ.* Seeds of an Australian plant, much the size of European chestnuts and having a chestnut-like flavor. The nuts which are somewhat rounded, spheroidal or flattened in form, are borne in pods an inch or more in thickness, and 6 or 8 inches in length. To some extent these nuts are roasted and eaten by the natives but are not altogether pleasant. To a limited extent this species has been introduced into southern California.

Cocos nucifera. Coconut. *Palmaceæ.* The well-known roundish or oval, nut-like seed, 3 or more inches in diameter, of a palm widely grown throughout all tropics. From the nuts, which are borne incased in very thick fibrous husks, is obtained the world's greatest food-supply. The flesh is wholesome either green or ripe, and either raw or cooked. The milk affords a very refreshing drink and the dried flesh, called "copra," is exported in enormous quantities. Coconut oil is one of the chief articles of export from the tropics. It is used in the manufacture of transparent and "marine" soaps. It is also largely used in pharmacy as a substitute for lard because of its less tendency to rancidity. Figs. 1011–1015.

Cola acuminata (*Cola*, or *Bichea, acuminata*). Cola. Kola. Bissey-bissy. Korra. Kolla. Gorra. Goora. Guru. Temperance-Nut or Ombene-Nut. Soudan Coffee. *Sterculiaceæ.* The seeds of a large African tree, from which is obtained the stimulating drink, long used in the tropics and now very common as a summer drink in this country. The seeds are borne in long pods, containing from five to twelve seeds each. The cola-nut is described in the "United States Dispensatory," as being "irregular in form, reddish gray in color, from ¾ of an inch to 1¼ inches in length, flattened and rounded upon one surface, irregularly scooped or unfolded upon the other surface, the nut being apparently a cotyledon marked above with another cotyledon which it has embraced."

Corylus spp. Hazel-Nut. Filbert. Cob-Nut. *Betulaceæ.* The seeds of a plant usually of shrubby habit of growth, but with at least one exception (*C. Colurna*), developing into a large tree, which is well known throughout much of the North Temperate zone in both the Old World and the New. Form globular, short, flattened, or oblong-flattened, the oblong types usually being wedge-shaped at the apex, and all types having a large light colored scar covering the whole of the basal end, marking the point of attachment. In color the hazels somewhat resemble the chestnuts but are of a lighter and more yellowish brown. Within the shell, which is usually thin and easily cracked is a single, dry, tough, or firm kernel, usually of sweet and agreeable flavor. Figs. 1073–1075; 1788.

The following include the principal species which are now looked upon as being of cultural importance: *C. americana*, American hazel, northern United States and Canada; *C. californica*, California hazel, western United States; *C. rostrata*, beaked hazel, northern United States and Canada; *C. Avellana*, European hazel, hazel-nut, nuttal tree, bread-nut, filbert, filberd, filbeard, philbert or cob-nut, southern Europe; *C. Colurna*, Constantinople hazel, Asia Minor, China; *C. maxima*; (*C. tubulosa*), Lambert's filbert, Europe.

Crescentia Cujete. Jicara-Nut. *Bignoniaceæ.* According to Fuller, in the "Nut Culturist," the name jicara-nut is applied locally in some of the Central American states, to the fruit of the evergreen calabash tree. Fruits vary greatly in both size and form, some being small and others from 18 to 20 inches in diameter. Some are symmetrical while others are of quite irregular form, but typical specimens are globular. They have a hard outer shell and an inner pulp which supports the seeds. The empty shells are used as drinking vessels and because of their ability to resist fire are considerably used as kettles for culinary purposes. Fig. 1106.

Cyperus esculentus. Chufa. Earth Almond. Rush-Nut. Edible Rush. *Cyperaceæ.* The small edible tubers of a sedge plant which, to a considerable extent, are grown in warm climates as a food for swine. Native to southern Europe. For fuller account, see *Chufa* and *Cyperus esculentus* in Volume II. Figs. 959; 1194.

Durio zibethinus. Durian-Nut. *Bombacaceæ.* The seed of a large forest tree of the East Indies and the Malay Peninsula, resembling the American elm somewhat in general appearance. According to Lindley, in "The Treasury of Botany," "The fruit varies in shape, being either globular or oval, and measures as much as 10 inches in length; it has a thick hard rind, entirely covered with very strong sharp prickles, and is divided into five cells, each of which contains from one to four seeds rather larger than pigeon's eggs and completely enveloped in a firm luscious-looking, cream-colored pulp, which is the edible portion of the fruit."

Lyons, in "Plant Names, Scientific and Popular," says that the fruit is "delicious in flavor, but of intolerable odor."

The seeds are roasted and eaten as are chestnuts. Numerous efforts have been made to establish this plant in Florida but thus far without success, due partly to the difficulty in shipping the tender plants, and also because of the inability of the species to endure the Florida climate. See also *Durio*, page 1081; Fig. 1366.

Elæis guineensis. Palm-Nut. *Palmaceæ.* The small irregularly formed seeds of a tropical African palm, famous for its production of palm-oil or palm-butter, as it is also called, which is largely used in the manufacture of soap and to some extent as a coloring-matter for oleomargarine. Nuts measure from 1 to 1½ inches in length by about ¾inch in greatest thickness. They are very hard, have a thick ivory-like flesh and a small cavity in the center. The nuts are encased in a fibrous covering which contains the oil. According to the Kew Bulletin, "Three varieties of nut trees are distinguished, having orange, red, and black nuts respectively, the first having the finest oil but small kernels, the others less oil but large nuts." The oil is extracted by boiling the nuts.

Lindley, in the "Treasury of Botany," says that of the shells, which are very hard and capable of taking a high polish, the negroes make rings and other ornamental articles.

Euryale ferox. Fox-Nut. Gorgon- (Greek meaning terrible) Nut. *Nymphæaceæ.* The spiny-covered edible seeds of a handsome, floating water-plant of eastern India. Believed by the Hindoo physicians to possess certain medicinal properties. It has long been cultivated in China and now to a considerable extent is common in the milder portions of the temperate United States.

Fagus grandifolia. American Beech-Nut. *Fagaceæ.* Small triangular seeds which in form and general appearance greatly resemble overgrown seeds of buckwheat. In character of shell and in flavor of kernel, beech-nuts greatly resemble the chestnut. Owing to the tediousness of separating the kernel from the shell, these nuts are not so largely harvested as undoubtedly would otherwise be the case. Figs. 1474–5.

From the seeds of the European beech (*Fagus sylvatica*), which also are edible, there is obtained a valuable oil, used as food and in the manufacture of soaps and as an illuminant.

Fusanus acuminatus (*Mida acuminata*). Quandong- or Quandang-Nut. *Santalaceæ.* The spherical, yellowish, rather thick-shelled seeds of an edible Australian tree-fruit called the "native peach." Of about the size of marbles. Surface covered with numerous small but deep pits. Kernel single. The fruit is quite edible and is locally used as a preserve.

Gevuina Avellana. Chilian-Nut. Chile Hazel. Avellano. *Proteaceæ.* Fig. 2539. Small seeds of an evergreen tree from Chile. Globular in form, with smooth, tough shell and a kernel much like that of a hazel in both appearance and flavor. Seeds borne within a coral-red fruit. Cultivated to some extent in California.

Ginkgo biloba. Ginkgo-Nut. *Ginkgoaceæ.* The oval, creamy white seeds of the ginkgo or maidenhair tree from China and Japan, which, to a considerable extent, is a familiar ornamental tree in temperate America. The nuts measure about ⅞inch in length, by ⅝inch in width, by ½inch in thickness. They have smooth and thin, but stout shells, within which are single green-colored kernels of rather sweetish flavor. When roasted, the kernels are said to be very palatable and are highly prized by the Chinese. At best, however, ginkgo nuts are inferior to most of the nuts on the market and are therefore not popular with the American people. Figs. 1640–42.

The fruit of the ginkgo considerably resembles that of the native persimmon in color, size and character, but differs from it in that the ginkgo flesh is of a disagreeable odor.

Guilandina Bonduc. Nicker. Nickar. Bonduc-Nut or Bezoar-Nut. *Leguminosæ.* The blue-gray, irregularly rounded, smooth-surfaced, beautiful seeds of a climbing legume of the tropics. The seeds are somewhat less than an inch in greatest diameter and have very hard shells. They are used as beads and to some extent for medicinal purposes.

The species has a very wide distribution caused by the seeds being transported by ocean currents; their imperviousness enabling them to be carried by waves for an indefinite length of time.

Hybrid nuts of the family *Juglandaceæ.* Such crosses as the pecan with some other species of hickory; the Persian walnut with some species of black walnut; the eastern American black walnut with one or the other of the California black walnuts are not infrequently met with in nature. The trees resulting from such crosses are very un-uniform in their character and rate of growth, some being extremely slow to develop and others very rapid, while others range between these extremes. A number of the pecan and hickory crosses have attracted considerable attention, because of their vigor of growth and production, but none of commercial importance has yet come to public attention. Such crosses are known as "hicans." The more rapid-growing of the walnut hybrids are much in use as stocks for cions of the Persian walnut of California. Ordinarily the walnut hybrids bear very light crops and the nuts are of little value. See *Juglans.*

Crosses between the eastern and either of the California black walnuts are called Royal and those between any of the black and the Persian walnuts are called Paradox.

Hyphæne crinita. Hyphæne-Nut. Doum-Nut. Doom-Nut. Dom-Nut. *Palmaceæ.* The seeds of a slow-growing African palm. From specimens received at the Office of Seed and Plant Introduction, Department of Agriculture, it appears that there are at least two quite different types of nuts appearing under this name, both of which have been considerably employed as substitutes for the more expensive ivory-nuts (*Phytelephas Seemannii*) of South America. Nuts of one of these types are of a light yellowish outer color, irregularly jug-shaped, approximately 2 inches thick by 2½ inches long, and covered with a smooth-surfaced fibrous husk ⅛ inch thick. Nuts of the other type are somewhat larger, less regular in form, and of a buff-color, but having much the same sort of outer husk and inner characters. The thick wall of pure white, hard flesh within the woody shell of each is used in the making of buttons, but reports from American and German manufacturers are to the effect that buttons of this material are much inclined to warp and shrivel.

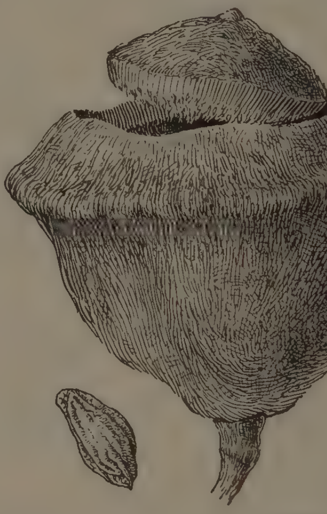
Inocarpus edulis. Tahitian, South Sea, Fiji, Polynesian, or Otaheite Chestnut. *Leguminosæ.* The seed of a tree native to the South Sea and neighboring islands. Borne singly in flat, fibrous pods, having a smooth outer surface. They are thin and somewhat wedge-shaped. Typical specimens measure approximately 2 by 1¾ by ¾ inches. When prepared by roasting or boiling, these nuts are said to have a chestnut-like flavor.

Jatropha Curcas. Physic-Nut. French Physic-Nut. Barbados-Nut. Purging-Nut. *Euphorbiaceæ.* Small, oblong, rounded seeds of about ¾ inch long, 7/16 inch wide, by ⅜ inch thick, of a slatish color, and having a thin strong shell, of a shrubby, tropical American tree. From the kernel, which is white and solid, there is obtained a strong purgative oil (curcas oil) which is also used for illuminating purposes. To some extent, this tree is grown in the warmer parts of the United States, but probably only as an ornamental.

Jubæa spectabilis. Coquita-Nut. Juba-Nut. Coker-Nut. Dwarf Coconut. Monkey's Coconuts. *Palmaceæ.* Small globular nuts 1 inch or less in diameter, having a smooth-surfaced, rather thick and very hard shell, within which is a flesh and open center much like that of the common coconut. The seeds of the wine palm of Chile. Consul Clement S. Edwards, in the "Daily Consular and Trade Reports," says: that "Coquito-nuts (little coconuts) are found in this region (Mexico), but the entire amount gathered is taken by the local soap manufactories, the managers of which are constantly complaining that they cannot procure sufficient material from this (Acapulco) neighborhood for their needs."

Juglans spp. Walnut. Butternut. *Juglandaceæ.* The nuts of a very important group of trees, representative species of which are found in many parts of the world, usually in the temperate zones. To this group, which is closely related to that of the hickories, belongs the well-known Persian, or more commonly called "English" walnut, the California product of which alone is annually worth more than double that of any other nut now grown in this country.

As with nuts of the hickory species, the walnuts vary greatly in size, form, thickness of shell, and, except in abnormal cases, which are very rare, the kernels are formed in two distinct halves, or cotyledons. The kernels of both are rich in valuable oils, which doubtless eventually will come into general use in the making of salads and for other purposes of cooking, but which are now used mainly in arts and paints, and as illuminants or lubricants. In color, the walnuts range from the light yellow or orange of the Persian walnut to the dark brown or black, of the black walnut. With the exception of the butternut, or the "white walnut," as it is quite largely known, which is fairly cylindrical, and about one-third longer than thick, and which has a rough sharp-pointed surface, the several species of American walnuts and a number of the foreign walnuts, are spherical or spheroidal in general form.



2540. Great nut of a lecythis, or monkey-pot. (×¼)

The usual difficulty with which the kernels are separated from the thick shells of the common butternut and black walnuts has prevented the nuts of either species from becoming generally popular on the market. Horticulturally speaking, there are now no recognized varieties of butternuts and but very few of black walnuts.

The list which follows includes practically all of the better known species of walnuts with their common names. For fuller accounts of each species, see Volume III: *J. australis,* Australian black walnut; *J. boliviensis,* Bolivian black walnut; *J. californica,* California black walnut (southern type); *J. Sieboldiana* var. *cordiformis,* Japanese walnut, heart-nut; *J. cinerea,* butternut, white walnut; *J. Hindsii,* California black walnut (northern type); *J. major,* Arizona black walnut; *J. mandshurica,* Japanese walnut, Manchurian walnut; *J. nigra,* American black or eastern black walnut; *J. regia,* Persian, English, Royal, Italian, Madeira, European, French, Chile, Caucasian, Manchurian, Circassian walnut; *J. rupestris,* Texas walnut, New Mexico walnut; *J. Sieboldiana,* Japanese walnut. Figs. 2011–2019.

Lecythis spp. Sapucaia- or Sapucaya-Nut. Paradise-Nut. Monkey-pot-Nut. *Myrtaceæ.* Fig. 2540. An oblong, irregularly shaped, though somewhat triangular nut, with irregular, longitudinal grooves over its whole surface, and having a rather thick, cork-like shell, which may be easily cut, and a single solid kernel, which considerably resembles that of the Brazil-nut (*Bertholletia excelsa*) to which it is closely related, but than which it is of much finer texture and of more delicate, pleasing flavor.

A quart or more of these nuts are borne in a heavily walled capsule of urn-shape, measuring from 6 to 8 inches in diameter at the middle, in the top of which is a perfectly fitting lid, from 2 to

4 inches across, which is said to be automatically thrown off with a sharp sound, by the contraction of the capsule at maturity. As the weight, which at that time must be from five to eight pounds, has caused the capsule to assume an inverted position, the nuts are scattered upon the ground. The scramble which follows of the monkeys and other small animals of the forest, to be first upon the scene for the nuts, has given this capsule the name of "monkey-pot," and the group of closely related species having similar capsules the name of the "monkey-pot group."

These species are native to much the same districts of South America as is the Brazil-nut.

Litchi chinensis (*Nephelium Litchi*). Litchi. Litschi. Lichi. Leechee. Litchee. Chinese-Nut. Chinese Hazel. Dawa-Nut. *Sapindaceæ.* A brown-colored, warty appearing fruit, in size and form resembling that of a strawberry, with an outer thin, papery shell, within which is a central smooth hard-shelled seed, surrounded by a brownish pulp of a delicious, subacid flavor. The fruit of a low-growing, tender tree, native to China. Under test for some years in Florida and in California.

Macadamia ternifolia. Queensland-Nut. Australian Hazel-Nut. Australian-Nut. *Proteaceæ.* A globular smooth-surfaced nut, of a light, yellowish brown color, 1 inch or less in diameter, with a very hard, rather thick shell, within which is a single kernel, resembling in form that of a hazel, to which it is greatly superior in richness and flavor. The fruit of an evergreen tree from Australia. There are a few trees of this species in California. Fig. 2241.

Manketti nuts. Mentioned in the "Daily Consular and Trade Reports," October 23, 1912, as having comprised a trial shipment of 22,500 pounds, which had recently been made to Europe from German southwest Africa, with a view to testing their commercial value. The nuts were said to have been gathered from wild trees in the neighborhood of Tsumed. According to this report, "It is said that the natives and bushmen eat the fruit without any ill effects." Efforts to find reference to the name "manketti" in botanical works have thus far met with failure. It is suspected, however, that the article from which this citation was taken had reference to the palm-nut, *Elæis guineensis.*

Mauritia flexuosa. Miriti- (Me-rish-i-e), Ita- (I-te) Palm-, or Buriti-Nut. *Palmaceæ.* The wine-colored seed, with flattened ends, of a lofty tropical American palm. This seed, which is about equal in size to that of the Persian walnut, is covered with very regular, close-fitting scales, underneath which is a tough shell, encasing a single ivory-like, globular, and farinaceous kernel about 1 inch in diameter. Much used as a food by the natives.

Moringa oleifera (*M. pterygosperma*). Ben-Nut. *Moringaceæ.* The seeds of a species of small tree native to tropical Asia, from which is expressed the ben-nut oil, largely used in the manufacture of perfumery. Seeds small, papery white, winged, triangular and resembling buckwheat grains in form. Figs. 2387, 2388.

Nelumbo lutea. Nelumbo. Nelumbium. American Lotus. Water Chinquapin. Water-Nut. Rattle-Nut. *Nymphæaceæ.* The small dark blue, nearly spherical seed of the American lotus or great water lily. About ½ inch in diameter, with smooth surface and a strong shell, within which is an edible kernel. *Nelumbo nucifera* is eaten in China as a nut.

Ophiocaryon paradoxum. Snake-Nut of Guiana. *Sabiaceæ.* Described by Fuller, viz.: "A large, roundish fruit, about the size of a black walnut, the product of a large tree of the soapberry family, native of British Guiana. This nut takes its name of 'snake-nut' from the peculiar form of the embryo of the seed, which is curled up spirally.

"The Indians, thinking there must be some virtue in form, use these nuts as an antidote for snake-bites, although so far as known to science they do not possess any medicinal properties."

Panax trifolium. Ground-Nut. *Araliaceæ.* The globose, pungent-tasting nut of the dwarf ginseng of the northern states. Of about the size of a radish.

Parkia africana. Nitta- or Nutta-Nut. *Leguminosæ.* Edible seeds, borne within the long clustered pods of the African locust tree. The pods, containing a sweetish farinaceous pulp within which the seeds are imbedded, are eaten entire, as is the carob or St. John's bread.

Pasania cornea. Edible Acorn. *Fagaceæ.* The seed of an evergreen tree of China, closely related to the oak. Now being tried out in this country by the Office of Foreign Seed and Plant Introduction, which says regarding it: "The nuts are as thick-walled as hickory-nuts; the kernels are white and of characteristic shape, and have a sweet, very agreeable flavor. In China, they are sold on the markets as are chestnuts here."

The nuts are very broad in proportion to their length, presenting a flattish appearance.

Pasania cuspidata. Edible Acorn. *Fagaceæ.* Described by the Office of Foreign Seed and Plant Introduction, by which it is being tested in this country, with stock from a Yokohama nursery, as being "A small acorn, edible and sweet, when ripe or after frost, boiled or roasted." From Formosa, Korea, and milder parts of China.

Phytelephas Seemannii. Ivory-, Tagua-, Taqua-, or Vegetable Ivory-Nut. Negro's-Head. *Palmaceæ.* The rounded, somewhat wedge-shaped seeds, or nuts of a low-growing reclining Central American palm, which in size and form greatly resemble very large chestnuts. Each nut is covered with a smooth, thin but strong shell of a light yellowish color, mottled with brown. The flesh is solid, pure white or creamy white, and capable of taking a very high polish. When cut or turned, they are used as a substitute for ivory in the manufacture of buttons, toys, and various kinds of ornamental work.

These seeds are borne in large compound chambers compactly joined together into heads a foot or more in diameter and covered with a sharp thorny surface, of a gray color. Each chamber contains from four to nine of the nuts, each of which is encased within its own shell.

The manufacturing of useful articles from ivory-nuts for the household is a very important industry in Germany, Hamburg being one of the chief centers.

Pinus spp. Pine-Nut. Indian-Nut. Piñon (Pin-yon). Pignolia. Pignon. *Pinaceæ.* The seeds of a considerable number of both foreign and American pines having rich, edible kernels which form an important article of food in many sections where the species are indigenous. Probably the largest of edible pine seeds are those of the Araucarian pines of Chile, of which there are several species. Not infrequently, seeds of these pines exceed 2 inches in length.

Of commonest appearance in our American markets are the seeds of the stone pine, *P. Pinea*, of southern Europe, which are sold under the names of "pignolia," or "pine-nuts," and to an increasing extent under the Mexican name "piñon," which originally was applied only to the seeds of certain American pines of the Southwest. As marketed, these nuts usually appear without the shells, in which condition they greatly resemble puffed rice.

Although some 12 or 15 species of American pines yield edible nuts, their product is seldom seen in any but the western markets, as it is largely consumed locally by the Indians of the Southwest and the Mexicans. These nuts are known as "piñons," "pine-nuts," and "Indian-nuts."

While none of the seeds of the American group are large, they vary greatly in size, form, and color. In flavor of kernel they are much alike. Usually they are irregular in form, longer than thick, sometimes slender but generally of about the same diameter each way. They range from ⅛ to ⅞ inch in length. In color they run from a light yellow, on one side at the basal end, to a brownish black at the opposite end, with a coffee-brown probably predominating.

The following list includes the names of the more important pines which bear edible nuts: *Araucaria braziliana*, Chile; *A. imbricata*, monkey puzzle, Chile; *Pinus albicaulis*, white bark pine, western United States; *P. cembroides*, Arizona piñon, southwestern United States; *P. Coulteri*, big-cone or Coulter's pine, western United States; *P. edulis*, piñon, southwestern United States; *P. Jeffreyi*, black pine, western United States; *P. Lambertiana*, sugar, shade, gigantic, or purple-coned pine, western United States; *P. monophylla*, single-leaf, or gray pine, western United States; *P. monticola*, mountain, finger-cone, or western white pine, western United States; *P. Parryana*, Parry's pine, or Mexican piñon, western Mexico; *P. Pinea*, stone pine, seeds called pine-nuts, pignolia, piñon, and pignon, southern Europe; *P. Sabiniana*, digger or gray-leaf pine, western United States; *P. Torreyana*, Torrey, Soledad, or Delmar pine, southern California.

Pistacia vera. Pistache. Pistachio-Nut. Green Almond. Fistiche. *Anacardiaceæ.* Fig. 2539. A small nut about ¾ inch long and slightly more than half as thick, which usually appears in the market with its thin, brittle shell partially split open, and with its kernel having a distinct salty taste. This is the seed of a Syrian tree which has been split open while maturing and which later has been roasted and salted. Typical kernels are of a distinct greenish color throughout and have a mild agreeable flavor. When ground, these kernels are used to a very large extent to afford the color and flavor of certain confections, especially ice-cream.

Trees of *P. vera* are fairly common in nut orchards of interior southern California, New Mexico and western Texas.

Prunus Amygdalus. Almond. *Rosaceæ.* Familiar products in all nut markets. To a considerable extent the form of the almond resembles that of an oyster-shell, although there is a very great variation in the length and width of the nuts of different varieties. Some are long and narrow, others short and thick, while still others range between. The shells of some are very thin, breaking readily when crushed together with one hand. These are called paper-shells. Others, called hardshells, require a sharp blow with a hammer for cracking. Almonds ranging between the hard and the paper-shells are called soft-shells. As they appear in the markets, almonds usually are of a uniform light yellowish color, which has been given them by artificial bleaching. The normal color is of a rather dull yellow, or as in the case of the hardshells, a brown closely resembling that of a peach pit.

At present the almond is the third most important nut crop in the United States, the first being that of the Persian or English walnut, and the second, the pecan. The entire output from this country is produced from beyond the Rocky Mountains, mainly from the Sacramento Valley of California.

Pterocarya fraxinifolia. Winged Walnut. Caucasian Walnut. *Juglandaceæ.* Small, angular, winged seeds, having hard shells, of a tree, native to western Asia. Of no economic importance. This and several other species of Pterocarya are employed to a considerable extent as ornamentals in the milder portions of temperate America.

Pycnocoma macrophylla. Bomah-Nut. Boma. Bome. *Euphorbiaceæ.* The seed of an African shrub used in tanning, and which yields a fixed oil.

Pyrularia pubera. Buffalo-Nut. Oil-Nut. Elk-Nut. *Santalaceæ.* The small seed of a pear-shaped drupe, which is the fruit of an eastern American shrub native from Pennsylvania to Georgia. About 1 inch long, subglobose, thin-shelled, and containing a kernel rich in oil and of a strong acid flavor. Without economic value.

Sapium sebiferum (*Stillingia sebifera*). Tallow-Nut. Chinese Tallow-Nut. *Euphorbiaceæ.* The whitish colored fruits, about ⅛ inch in diameter, of a Chinese tree. Borne singly in three-chambered capsules. The nuts consist of relatively large, brown seeds, having hard shells with a thick coating of a fatty substance, which is used in various ways as a substitute for animal tallow. From China and Japan.

Semecarpus Anacardium. Marking-Nut. Marany-Nut. Marsh-Nut. Oriental Cashew. *Anacardiaceæ.* Fig. 2539. The black, lobe-like, somewhat contorted seed of about 1 inch in length, by ¾ inch wide, and ⅜ inch thick, of an evergreen tree native to the warmer parts of Asia. A very useful ink is made by mixing lime with the green juice of these seeds. It is said that to a considerable extent the natives roast and eat these seeds.

Unless roasted, these nuts should be handled with great precaution, as in the raw condition they possess extremely poisonous properties similar to those of the American poisons, ivy and sumac, and the cashew, to which it is closely related.

Staphylea trifolia. American Bladder-Nut. *Staphyleaceæ.* The fruit of a shrub common in eastern and northern United States. Triangular in form, measuring from 1¼ to 1¾ inches in length by about ¾ inch in width, covered with a thin papery shell of a reddish brown or buckwheat color, and having a rather long, sharp point at the apex. Fruit three-celled, each cell containing several (usually three) small, smooth and very hard shining seeds. Fruits remain on shrubs during winter. Of use only as ornamentals.

Strychnos potatorum. Clearing-Nut. Indian Gum-Nuts. Water-filter-Nut. *Loganiaceæ.* The seed of an oriental tree, which is largely employed by the natives because of its power of causing impurities in water to settle to the bottom. Receptacles in which water is to be placed are vigorously rubbed with one of the nuts; later the water is poured in and the impurities quickly unite together at the bottom, leaving the water perfectly clear.

Telfairia pedata. Tabebuia. *Cucurbitaceæ.* Fig. 2539. The thin, broad seed, in form resembling a longitudinal section of a shortened tulip bulb, of a rapidly growing tropical climber from Africa. Typical specimens measure about 1¼ inches in length, by slightly more in width, and about ⅜ inch in thickness. They are covered with a tough fibrous seedcoat of a straw-color. Within this is a solid palatable kernel, resembling the Brazil-nut greatly in texture and somewhat in flavor.

Terminalia Catappa. Tropical Almond. Demarara Almond. Malabar Almond. Myrobolan-Nut. Tavola-Nut. *Combretaceæ.* The oblong, broad-oval, smooth-surfaced seed, with a sharp ridge marking the sutures on the two sides, of a very tall deciduous tree of southern Asia. The long and very slender kernel, encased within the thick porous husk of this seed is said to have an almond-like flavor.

Theobroma Cacao. Chocolate-Nut. Chocolate-Bean. *Sterculiaceæ.* The dark reddish brown, bean-like seeds of a small genus of tropical America which affords the cacao butter of commerce. These seeds are about ⅞ inch long, by ½ inch wide and ⅜ inch thick.

Thespesia populnea. Portia-Nut. *Malvaceæ.* The small obovoid brown seeds of a tree, native to tropical parts of the Old World. Seeds have a netted veined surface, yellowish brown pubescence on inner edges, especially at apex, and a thin but stout shell. Portia-nuts yield an oil used as an illuminant.

Torreya nucifera. Torrey-Nut. False Nutmeg. *Taxaceæ.* The small brown-colored, somewhat mottled, thin-shelled, oblong-oval seeds, of a good-sized coniferous tree native to Japan. Eaten either raw or roasted.

Trapa natans. Water Chestnut. Water Caltrops. Water-Nut. Horn Chestnut. Jesuit Chestnut. *Trapaceæ.* Fig. 2539. The seed of a water-plant of southern Europe, much sought after by the natives for their agreeable kernels which become inedible with the hardening of the shell. In form, these nuts are very irregular, measuring from 2 to 3 inches between the tips of the short stout horns, and about 1 inch in depth through the irregularly shaped head of the nut. These nuts are of a slatish brown color and their surface is quite smooth.

Trapa bispinosa. Singhara-Nut. *Trapaceæ.* Fig. 2539. Southern Asia and northern Africa. According to Watt, in the "Commercial Products of India," "This aquatic plant has been grown in India from the most ancient times. . . . In certain parts of the country the kernels are ground down and employed for making the colored powder (gulal) used during the Holi festival." They are also used medicinally and as a staple article of food.

In growing, the nuts "mature under water" and are "gathered in November and December." In certain sections it is "extensively cultivated, e. g., in Kashmir, the United and Central Provinces, etc.

"The kernel abounds in starch, and is eaten either raw or cooked, especially by the Hindus. It may be boiled whole, after soaking a night in water, roughly broken up and made into a sort of porridge, or ground to meal and into chapattis."

THE COMMON NAMES OF NUTS WITH THEIR TECHNICAL EQUIVALENTS, UNDER WHICH THE NUTS ARE DESCRIBED.

Acajou	*Anacardium occidentale.*
Acorn, edible	*Pasania cornea.*
Acorn, edible	*Pasania cuspidata.*
Almond (of commerce)	*Prunus Amygdalus.*

NUTTÁLLIA: *Osmaronia.*

NYCTÁNTHES (*night flower:* blooms toward night and fls. fall at morning). *Oleàceæ.* One species, a small tree or shrub of India but now spontaneous in some other countries, sometimes planted in warm regions or grown under glass for its numerous white very fragrant flowers.

The species is **N. Árbor-trístis,** Linn., literally the "tree of sadness" because it blooms only at night; it is also known as the "night jasmine." Nyctanthes is much like Jasminum and some of the early names belong under that genus; it differs in its capsular fr. Lvs. opposite, ovate, cordate, short-stalked, entire or dentate, scabrous: branches 4-angled: fls. few in a sessile involucrate cluster or head, which are disposed in dichotomous cymes; corolla whitish, the tube orange, salverform, the lobes 4–8; stamens (anthers) 2, nearly sessile near the top of the tube; ovary 2-celled, the style short and stigma 2-lobed: caps. roundish, ¾ in. long, with one erect seed in each of the 2 cells. B.M. 4900. B.R. 399.—It is an interesting plant, but little grown in our territory; blooms in summer; prop. by firm cuttings in sand with bottom heat. Reaches 30 ft. in India.

L. H. B.

NYCTERÌNIA: *Zaluzianskya.*

NYCTOCÈREUS (*night* and *cereus*). *Cactàceæ.* A slender cactus, at first erect, then clambering, with few branches; the st. has many low ribs with closely set areoles producing 10 or more acicular spines: fls. large, nocturnal, white; tube and ovary covered with small bracts, producing in their axils small clusters of spines: fr. red; seeds black.—Several species are known. They are among the several kinds of night-blooming cereus. See *Succulents.*

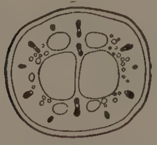
serpentìnus, Brit. & Rose (*Cèreus serpentìnus,* DC.). Sts. 5–8 ft. long, slender, flexuous; ribs 10–13, low, obtuse; spines acicular: fls. 6 in. long. Mex. B.M. 3566.

guatemalénsis, Brit. & Rose. A recently described species which has been widely intro. into Eu. and is being grown to some extent in this country. It grows easily in cult. It is not so tall as *N. serpentinus,* but the tips of the sts. are inclined to bend over and take root and start new plants. J. N. Rose.

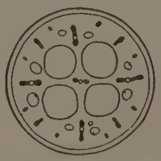
NYMPHÆA (from *Nympha,* in Greek and Roman mythology, a nature-goddess). Syn., *Castàlia. Nymphæàceæ.* Water-Lily. Pond-Lily. Nymphea. The most showy of aquatics (except Victoria), inhabiting the North and South Temperate and Tropical zones.

Herbs, perennial by horizontal or erect rootstocks or tubers, rooting in mud, covered by 3 in. to 6 ft. of water (rarely in bogs not submerged): lvs. floating, or when crowded rising a few inches above the water, round or oval, entire or dentate or sinuate, fissi-cordate, often sub-peltate, 2 in. to 2 ft. across: fls. mostly showy, white, yellow, blue, and red, in all shades, 1–12 or 14 in. across; sepals 4; petals and carpels many; stamens numerous; pistil with a broad cup-like depression in the center of the fl., surrounded by a ring of fleshy processes, the carpellary styles, and with a knob at the center.—About 40 well-marked species, with numerous local varieties and many cult. hybrids.

The petals and stamens of Nymphæa appear to be attached to the sides of the ovary; but this surface is to be considered as the outside of a cup-like receptacle, its cavity being completely filled by the radially placed carpels, with whose backs it is fused. Several species show easy gradations from sepal to petal and from petal to stamen, thus illustrating the homology of floral parts. The peduncles and petioles are traversed by a number of longitudinal air-canals, from whose walls star-shaped cells and rounded cell groups project inward; in the walls of these stellate internal hairs, are imbedded numberless minute crystals of calcium oxalate; they are objects of great beauty in microscopical sections. The distribution of these, as also of the air-canals, differs in different species. (Figs. 2541 to 2544.) Three types of leaf may be distinguished: (1) Very thin and fragile submerged leaves on short petioles; (2) floating leaves, thicker in texture, with stomata and palisade cells on the upper surface only; (3) aërial leaves, leathery in texture, sometimes, at least, bearing stomata on the under surface.

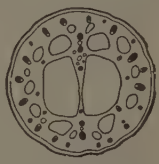


2541. Transverse section of petiole of Castalia group.

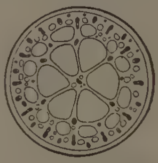


2542. Transverse section of peduncle of Castalia group.

The leaves spring from the rhizomes in spiral orders of varying complexity, from two-fifths up. The growing apex of the stem is protected by the colorless stipules and a dense growth of long fine hairs. A group of roots comes off from the stem just below each leaf. The flowers are extra-axillary, arising as members of the leaf spirals or in a spiral of their own. The rhizomes of species which dry off in the resting season (Lotos, Hydrocallis; Apocarpiæ) become protected by a strong corky bark; others remain continually in a state of more or less active growth.



2543. Transverse section of petiole of Lotos group.



2544. Transverse section of peduncle of Lotos group.

Habits of opening.—The flowers of every species open and close at a particular time each day, so that in a pond with eighteen or twenty kinds there is some change taking place at almost all hours. The hours of blooming are fairly regular, though the tropical species are more sluggish in cool weather, and the hardy ones are irregular in very hot times. Each flower opens from one or two to five or seven successive days (or nights), being about an hour later to open and an hour earlier to close on its first than on subsequent days. The flower then goes down into the water by a spiral coiling of the peduncle (or simply bending over if in shallow water), where the seed ripens. When in six to ten weeks the pod matures and bursts, the seeds rise to the water-surface and float for several hours by means of a buoyant aril. This finally decays and drops the seed at some distance from the parent. To secure these, the floating seeds may be dipped up in a wire sieve, or better, the pods may be inclosed in muslin or cheesecloth bags before ripening, all of the seeds being thus secured.

The hybrids.—The species of a single group hybridize very readily among themselves, and in the Lotos and Fucastalia groups the hybrids are more or less fertile. By means of this condition all shades of color have been obtained, from the pure white *N. Lotus* var. *dentata* to the dark crimson-red *N. rubra.* In this group and in Castalia varieties have so multiplied of late and fanciful names have been so freely given that an accurate classification of all of them is no longer possible. In the Brachyceras group, hybrids occur almost certainly if *N. zanzibariensis* is grown in the same pond with others of the group; thus have originated some very fine varieties. Outside of single groups, no genuine hybrids have yet been produced. Between the apocarpous and syncarpous species, a hybrid would be impossible. Authorities differ as to the best time to transfer pollen. Certain it is that the flowers are pistillate on the first day of opening, the pollen being shed on succeeding days or late on the first day. Some say that pollination should take place in the early morning hours, about daybreak; others consider the time most favorable just as the flower is closing for its first time.

Trouble with the names.—The water-lilies and yellow pond-lilies or spatterdocks were together included by Linnæus under the genus name Nymphæa. In 1805 Salisbury first separated these two parts of the genus. The water-lilies he called Castalia and the spatterdocks Nymphæa. J. E. Smith, writing two years later, disregarded Salisbury's work and called the two groups Nymphæa and Nuphar respectively. Thus Castalia, Salisb.=Nymphæa, Smith, and Nymphæa, Salisb.= Nuphar, Smith. Salisbury, contrary to good usage and the present International Rules (article 45), coined a new name for the group containing the larger number of species, and arbitrarily changed nearly all of the specific names. His names, however, never came into general use, but Smith's were generally adopted. Strict adherents of the "law of priority" have recently revived the generic names of Salisbury. The principle of fifty years of accepted usage may well be extended to this case, making it unnecessary, as it is also unfortunate, to revive the old name Castalia for these well-known and popular plants, which are habitually monographed under Nymphæa. The name Castalia is not adopted by most European botanists. Briquet, of the international committee on nomenclature and under whose name the international rules are issued, writes the author that the rules definitely mean to authorize Nymphæa rather than Castalia.

Until the first edition of this Cyclopedia, several specific names were confused, but this difficulty is mostly corrected now. In reading of aquatics prior to 1900, it is well to remember that many British botanists include all blue water-lilies of the eastern hemisphere (or all except the Australian forms) under the name *Nymphæa stellata*. *N. cærulea* of B. M. 552 and *N. scutifolia*, DC., are really *N. capensis*. The true *N. cærulea* was long known in American gardens as *N. scutifolia* (Tricker, "Water Garden," 1897). *N. ampla* of gardens may be either *N. amazonum* or *N. Lotus* var. *dentata* (see "Waterlilies: A Monograph of the Genus Nymphæa;" by H. S. Conard. Carnegie Inst. Publication No. 4).

The true Egyptian lotus.—Among common names the term "lotus" has been remarkably misapplied. It seems to be consistently used among us for the genus Nelumbo, *Nelumbo nucifera* being generally styled "Egyptian" or "sacred lotus." Historically this is entirely wrong. Nelumbo is not native in Egypt, and is not now found there in a wild state. It was cultivated extensively along the Nile in the Roman period, probably for food, and the flower is supposed to have furnished the design for one form of capital of the Egyptian columns. It is a native of southeastern Asia; is found near temples and carved on the walls of cave-temples in Hindustan, showing a veneration, which it shares, however, with *Nymphæa stellata*, *N. rubra* and *N. Lotus*. Nelumbo seems to have been regarded as sacred about temples in Japan and China. In Egypt, however, *Nymphæa cærulea* and *N. Lotus*, the "blue lotus" and "white lotus," are indigenous. The root (rhizome) of the former is said to have been pointed out as edible by Isis—or by Menes; its flowers, buds and leaves are often depicted on the monuments, the first sometimes in color. The flowers are figured among offerings under the fourth dynasty (3998–3721 B.C.), and the plant is certainly known from the fifth dynasty. Petals of this and of *N. Lotus* were found in the tomb of Rameses II, the Pharoah of the Israelitish captivity. *N. Lotus* was less regarded than *N. cærulea* in Egypt, though an object of veneration in India. Herodotus and other ancient writers speak of these water-lilies indiscriminately as the "lotos" of the Egyptians. With these facts, and the additional one that, except as referred to above, Nelumbo never appears in Egyptian carvings, the identity of the sacred lotus cannot be doubted. But the erroneous use of the word lotus is deeply rooted and may never be supplanted, and it is necessary to remember that the so-called "Egyptian lotus" is not the plant of the tombs and monuments. (The lotus of Tennyson's poem, "Lotus Eaters," is still another plant, a shrub or tree, which hangs out over the water; and the genus Lotus [which see] is distinct from all of these.)

The Marliac hybrids.—Two types of hardy free-flowering hybrids akin to *N. alba* and its variety *rubra*, but of uncertain parentage, have been introduced since 1888, one of sturdy habit, raising its leaves (4 to 8 inches across) and flowers (3 to 6 inches across) well out of the water when crowded, the other slender in growth, the leaves (3 to 6 inches across) and flowers (2½ to 4 inches across) usually floating. From 1888 to 1900 all of these superb varieties were introduced by M. Latour-Marliac of Temple-sur-Lot, France, whose methods, however, remain a mystery. Excellent culture combined with careful selection and wise hybridization have brought about these magnificent results. The first or Marliacea group seems to involve *N. alba* as one parent. The second started with a hybrid of *N. alba* var. *rubra* and *N. tetragona* known as *N. Laydekeri* var. *rosea*, to which is added in varying degrees blood of *N. alba* var. *rosea* and *N. mexicana*. But this does not adequately account for the whole group. Nearly all kinds of both groups are entirely sterile.

Important species.—The following account, which contains 200 varieties and about 48 synonyms, may seem rather formidable to the beginner, but the species of first importance are only eight in number: *N. Lotus*, *N. rubra*, *N. tuberosa*, *N. odorata*, *N. alba*, *N. mexicana*, *N. flavo-virens* and *N. zanzibariensis*. The greater number of the other names represent garden varieties and hybrids. It is impossible for any form of arrangement to be clear and logical on the one hand, and exhibit natural relationship on the other, at least, in a genus so greatly modified in cultivation. However, the true species may be distinguished in the treatment, the derivatives being apparent by description or hybridization sign (×) or otherwise.

The best water-lilies for amateurs.—Tender day-blooming kinds: *N. pennsylvania*, light blue; *N. zanzibariensis*, deep blue; *N. flavo-virens*, white; Mrs. C. W. Ward, pink; *N. Daubeniana*, dwarf, blue. Tender night-blooming kinds: *N. dentata*, white; *N. Omarana*, magenta; Frank Trelease, dark crimson. Hardy kinds: *N. chromatella*, yellow; *N. tetragona helvola*, dwarf yellow; *N. Gladstoniana*, white; *N. tetragona*, dwarf white; W. B. Shaw, pink; *N. Laydekeri rosea*, dwarf pink; Wm. Falconer, dark red.

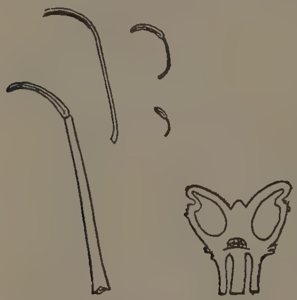
Cultivation of water-lilies. (William Tricker.)

Water-lilies or nympheas are among the most royal, gorgeous, diversified, and universally admired plants in cultivation. No class of plants in our public parks can compete with them in attracting the people. Moreover, America is the most highly favored country in the world for the cultivation of aquatic plants. Ours is the only country which can have so rich and continuous a display of aquatics in flower from April to October in the open without artificial heat. In parks and private gardens are to be seen, flowering early in spring, all native nympheas, and others from Europe and Asia. The species begin to flower in April and continue until early fall, when a number of the hardy hybrids continue to flower uninterruptedly until the end of the season. In the central states and southward, the hardy varieties decline when tropical weather sets in, and the nights and days are hot. In the eastern states, and especially near the coast, where the nights are cool, the season is much longer, and the color of some of the pink varieties is more intense. Following the hardy nympheas come the nelumbiums in all their oriental splendor, brightening the summer season, and bridging over the declining period of the hardy nympheas and the approaching season of the tropical nympheas which arrive at maturity toward the latter end of July or beginning of August, and continue until fall. Finally the grandest of all aquatic plants, *Victoria regia*, may be seen in America growing in a natural pond, and producing its chaste flowers as late as the middle of October.

America is rich in native species of nymphea, and it is the only country which has native white-, pink- and yellow-flowered kinds. Of the American nympheas there are about five that are best known. The common white water-lily is *Nymphæa odorata*. Its variety *rosea* is the Cape Cod pink water-lily. *N. tuberosa* (syn. *N. reniformis*) is a white-flowered species, inhabiting the western lakes. The yellow kind, *N. flava*, is indigenous to Florida and other southern states, but is hardy in New Jersey and southern New York. Another southern kind is the white-flowered *N. odorata* var. *gigantea*. In addition to the above well-known kinds, there are several distinct forms and hybrids.

The commencement of the cultivation of aquatics in

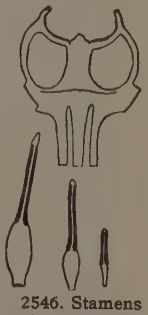
America led to the commingling of species, especially of *N. odorata* and *N. tuberosa*. The result is that in several sections are to be found many similar varieties, and forms of both white and pink, some of which are valuable, being distinct in color and having large, handsome, fragrant flowers, while a host of others are worthless, so far as distinct varieties are concerned. *N. tuberosa* is known as the largest and purest white water-lily, distinct in foliage, flowers and rootstock. This species has proved to be the most susceptible of cross-fertilization. One great hindrance to the cultivation of such half-breeds, is that most of them produce seed. The seedlings are either white or pink, and seldom, if ever, like the parent plant. There are in different sections of the country distinct forms of *N. tuberosa*, some having long, narrow petals and slightly fragrant flowers, others again having broad incurving petals, forming handsome cup-shaped highly fragrant flowers; still others have very full flowers, quite double, the numerous petals crowding each other until the reflexed sepals inclose the stalk, forming spherical flowers like balls of snow. *N. tuberosa*, in any of its forms, should not be planted in a small pond with other nympheas, for it is such a rampant grower that in a short time it will smother the less vigorous kinds. This species delights in plenty of space, and water 2 to 3 feet deep, with soil of a tenacious character. However, it will thrive in almost any soil, and is well adapted for naturalizing in lakes and ponds. Attempts at naturalizing or cultivating on a small scale have not been very satisfactory; but the species will well repay any extra care to establish it in desirable localities.



2545. Stamens and vertical section of ovary of Anecphya group.

Two or three species are indigenous to continental Europe, notably *N. alba*, the well-known English white water-lily, *N. candida*, the white Bohemian water-lily, and *N. alba* var. *rosea*, the Swedish water-lily. The last named is the only disinct or true red-flowered, hardy species. Still another species, which has played a very important part with specialists of the present day, is *N. tetragona* (*N. pygmæa*), from China and Japan.

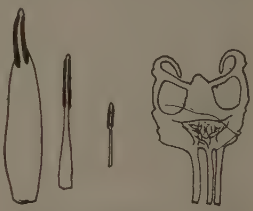
Nymphæa odorata was introduced into England during the eighteenth century, and was probably the first foreign nymphea to reach that country. Other species followed later, mostly tropical; but, although the English people were ardent horticulturists and lovers of the beautiful in nature over a century ago, nympheas never became popular, and remained a neglected class of plants until a few years ago, when N. Marliac, of Temple-sur-Lot, France, conceived the idea of crossing the English white water-lily with the well-known Cape Cod pink water-lily, and the Florida yellow variety. Nothing in the horticultural world has created more surprising results in the blending of the American and English species. These species have been the progenitors of numerous varieties, which have made this class of plants the most popular and desirable of all aquatic decorative subjects, and within reach of all. Their popularity has kept constantly increasing and ever heightened by new additions. America, also, has contributed its quota to the list of novelties, and some of these are unsurpassed by any European introductions.



2546. Stamens and vertical section of ovary of Brachyceras group.

From the apparently simple conditions under which our native species are found growing, many amateurs have concluded that all these plants require is water and possibly some mud to keep the roots in. Many attempts have been made to grow these plants in pails and tubs, with inevitable failure as a result. Professional gardeners, also, have made grievous errors, for, while they have used every means to secure fine specimen plants of flowers, vegetables and luscious fruits, they have usually given meager attention to water-lilies, and have not supplied half their wants. Water-lilies, all nympheas, succeed best when grown, as near as possible, under their existing natural conditions; these are a rich alluvial soil in abundance, water, and clear uninterrupted sunlight. Where natural ponds exist these conditions are found, but often there is a deficiency of light, caused by shade trees. Let the trees remain, but choose open spots for the nympheas. They may be planted on the margins of sluggish streams, in bays and sheltered nooks.

Where artificial ponds are used, the most satisfactory method is to build solid walls of reinforced cement, with a concrete bottom, provided with an outlet and overflow. In all cases make the pond as large as existing means will allow, not for a moment considering it possible to be too large. One method of providing for the sustenance of these plants is to place a layer of soil in the bottom of the pond from 9 to 12 or more inches deep. This will suit the plants admirably. Artificial ponds are usually constructed in a conspicuous spot, where everything is required to be well kept. In such situations it is necessary occasionally to take off some dead leaves, or cut a few choice flowers, and if they cannot be reached from the edge of the pond, the attendant must wade in after them. The result is that the water, which should always be clear, is muddy, and when it settles there is a muddy deposit on the leaves that makes them very unsightly. Moreover, this treading in the soft soil breaks numerous roots. To avoid these and other attendant evils, place the soil in boxes from 3 to 4 feet square, and 1 foot deep, and in these plant one single plant of the vigorous and moderate growers, allowing ample space between the boxes. One plant of any tropical water-lily in such a box, or three of smaller species, will require 50 to 100 square feet of water surface, as will also strong hardy nympheas, since these may remain two years undisturbed, although some of these are best replanted every season. The pond should be 2 to 2½ feet in depth. The soil should be a strong loam, the top-soil from a pasture composted with cow-manure in proportion of one-third. This should be prepared six months, at least, before planting time. This soil is suitable for all aquatic plants. In any case, when filling the boxes or placing the soil in bottom of pond, tread moderately firm and cover with an inch of sand. The water may be spring-water, rainwater or that from any available source. The clearest spring-water will soon turn green from exposure to the sun and air, but after fermentation settles clear. Do not place the plants in a newly constructed pond or basin immediately after it is finished, as the caustic property of the cement will injure the plants. Wash the new construction thoroughly and then supply it with clean fresh water. Planting of the hardy varieties may be done in April and May, according to the latitude and earliness or lateness of season. The conditions should be conducive to active growth at once.



2547. Stamens and vertical section of ovary of Castalia group.

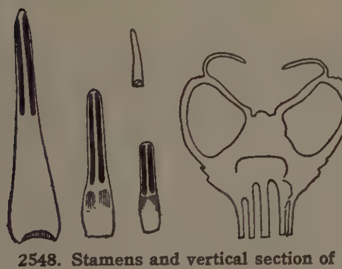
Tropical nympheas should not be planted until there is evidence that summer has come. Hardy nympheas may be planted in spring and summer (not in autumn); late planting is better than deferring till next spring, as the plants under such conditions will get established before autumn closes, and the plants will start naturally in spring, receiving no check.

The above method of construction and cultivation is to be commended, but other methods are adopted with a fair degree of success, but with attendant evils which are discouraging and at times very annoying and costly. Tanks or artificial ponds may be constructed with cement, digging the pond the desired size, having sloping sides and afterward lining the same with concrete and finishing with a facing of cement. However, such a pond will not stand the effects of hard freezing weather even if protected; and what is worse, the new or freshly removed soil will settle during the season, and the pond is very likely to spring a leak.

Another method of construction is to line the pond with well-tamped clay, from 4 to 6 inches thick, afterward covering with 2 inches of sand. The labor for such construction is expensive, however, the clay may not be good, and the pond is likely to be muddy; it is now better to build of cement.

There are yet the advocates for tub-culture. Plants will grow in tubs, and as soon as the plant-food is exhausted, which is often at an early date, the plants exist awhile and then draw out a miserable, exhausted and discouraging career. Fountain basins are often made the receptacles for nympheas. There they may be grown if the right conditions are accorded them, but there must not be a stream or spray of water running all the time, as the water may be cold, chilling the plants and checking their growth.

Nympheas have insect pests like other cultivated plants. Aphides are sometimes troublesome. The best remedy is their natural enemy, the "lady-bugs" or "lady-birds." A colony of these voracious insects makes short work of the aphides, as do also the lace-winged flies. An insect of recent acquaintance with nympheas is a leaf-miner, the larva of a small fly, which cuts channels through the leaf in all directions. Sometimes only a few of these are in evidence; at other times the leaves are fairly alive with them. The trouble is easily detected. A simple remedy is kerosene emulsion, applied with a fine spray at evening after the flowers are closed. Another troublesome insect is a leaf-cutter, *Hydrocampa obliteralis* (or *proprialis*). The larva cuts out pieces of the leaf and hides between two pieces, which makes a kind of tent. In this tent the larva moves about. At first it moves slowly, but as it nears maturity the larva becomes ravenous and then eats the surface of the leaves near the center, and cuts off much larger pieces of the leaf. The best remedy is a lamp trap for the mature insect. Frogs and dragon-flies will catch numbers of them. Arsenate of lead spray will destroy the larvæ.



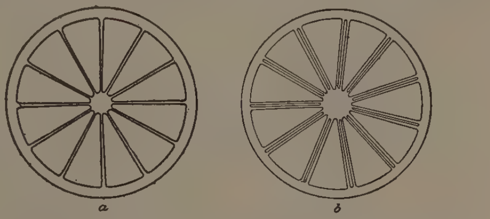
2548. Stamens and vertical section of ovary of Lotos group.

Nympheas are also subject to a fungous disease, a leaf-spot which is easily discerned after a spell of warm, humid weather. The leaves are scorched and crumpled, the plant is denuded of its foliage; new leaves are weak and smaller, and so too are the flowers, if indeed there are any. This disease must be checked at once or the plants will be severely set back, if not ruined. A remedy is bordeaux mixture. Use a fine spray, and dilute the mixture to half the strength recommended for most plants. It is best to spray twice with a weak solution rather than to spray once with a too strong solution and to damage the foliage. A light dusting on the leaves with carbonate of copper will soon remedy the trouble.

In winter, tender nympheas should be kept in tanks or tubs under glass. For hardy species, cover the tank with boards and pile on dry leaves, coarse hay or other material; or the roots may be taken out and buried in a sheltered place.

Water-lilies in California. (Edmund D. Sturtevant.)

The culture of nympheas in California presents fewer difficulties than in the eastern states. The varieties which are hardy in the East flourish equally well and bloom for a longer period. In frostless localities, especially where the lemon tree is free from injury, such tender varieties as *Nymphæa devoniensis*, *N. dentata* and *N. zanzibariensis* may be left in the open pond during the winter. In colder localities, the tubers should be removed to warmer quarters in November to remain until spring. If a greenhouse is not available, a small pool built in such a manner that it can be covered with hotbed sash will afford suitable protection. Very little room is needed for these when they are dormant. The manner of cultivating both the hardy and tender varieties is much the same in California as in the eastern states. For growing a small collection, a pool 8 or 10 feet across may be made by excavating 2 or 3 feet, making the walls of concrete, brick or stone, and covering the bottom with concrete. The best quality of cement should be used for all the work. An overflow pipe should be put in and so arranged that the pool may be emptied when occasion requires. Basins 20 or 30 feet in diameter, or even larger than this, are desirable for growing a good collection. In a small pool, wooden boxes 10 inches deep and 18 inches to 2 feet square may be used to hold soil for the plants. In a large basin some of the boxes may be 3 or 4 feet square. While most aquatics will flower freely in contracted quarters, they will attain greater perfection and produce much larger flowers if they have abundance of room.



2549. Transverse section of ovaries. ***a*, syncarpous, *b*, apocarpous.**

Most of these plants are gross feeders, and it is well-nigh impossible to make the soil too rich for them. It is not necessary to go to a swamp or natural pond to obtain what is suitable. Any soil that will grow good vegetables will, if properly enriched, grow water-lilies. A compost, consisting of two-thirds good soil and one-third thoroughly decayed cow- or stable-manure, with a sprinkling of bone-meal, is recommended. A dark friable loam, which is intermediate between "adobe" and sandy loam, is desirable for this purpose. The tenderest varieties, such as *N. devoniensis* and *N. dentata*, will flower for a long period without any forcing; but if started into growth in March in a greenhouse or hotbed and planted in the pond in May, there will be a great gain in the length of the flowering season. The soil for the tender varieties should be renewed every year, and that for the hardy ones every two years.

If aphides or the pest known as the leaf-roller make their appearance, the leaves, should be sprayed with kerosene emulsion very much diluted, using one part emulsion to fifteen of water. If large ponds or lakes with a natural earth bottom are used for growing water-lilies, care must be taken that noxious weeds do not get a foothold. Cat-tails (*Typha latifolia*) and "tules" or bulrushes are troublesome if not destroyed when they first make their appearance. Palms, both fan-leaved and feathery, giant bamboos, musas, strelitzias, papyrus, giant grasses, fatsia and caladiums are among the things which can be used to ornament the surroundings of the water-garden.

The genus Nymphæa divides itself readily into two main divisions, which again are subdivided into five subgenera as follows:

Section I. Apocarpiæ. Carpels free at the sides, united at their edges to the central column of the fl. and at their backs to the receptacle: outermost stamens ripening first, innermost last: rhizome ovate, stoloniferous.—Tender day-bloomers: fls. on strong scapes 4–12 or 14 in. above the water (*Lytopleura*, Casp.).

Subgenus I. Anecphya. Stamens all slender, half as long as the petals, almost without any appendage (Fig. 2545): carpellary styles wanting: fls. blue, rosy or white.—Two species, in N. Austral.

Subgenus II. Brachyceras. Outermost stamens with an appendage above the anther (Fig. 2546): carpellary styles short, triangular: fls. white, blue, pink or yellow.—About 15 species in the tropics all around the world.

Section II. Syncarpiæ. Carpels entirely fused together (*Symphytopleura*, Casp.).

Subgenus III. Castalia. Sepals not evidently nerved: carpellary styles flat, linear: outer stamens petaloid; innermost stamens first to ripen, their filaments short, narrower or but slightly wider than the anthers (Fig. 2547).—Hardy or half-hardy day-bloomers: fls. white, pink, red or yellow. In the entire North Temperate Zone, excepting the Pacific slope of N. Amer.

Subgenus IV. Lotos. Sepals prominently veined; a space between the insertion of the petals and stamens; stamens broad, flat, rounded at apex (Fig. 2548): carpellary styles linear: lvs. sharply dentate: rhizome ovate, stoloniferous.—Tender night-bloomers: fls. red or white on strong scapes 3–12 in. above the water, opening on 4 successive nights. Two or 3 species in S. Eu. and Asia and N. and Cent. Afr.

Subgenus V. Hydrocallis. Sepals not evidently nerved: carpellary styles long, club-shaped: petals in alternating circles of 4: stamens much as in Castalia, all opening about the same time: rhizome ovate, stoloniferous.—Tender night-bloomers: fls. creamy white. About 9 species in Trop. Amer.

The initial C in the synonymy=Castalia.

Section I. Apocarpiæ.

SUBGENUS I. ANECPHYA.

1. **gigantèa,** Hook. (*Castàlia gigantèa*, Brit.). Lvs. narrowly peltate, elliptic or ovate, margin sinuate-dentate, sinus open; under surface brownish pink to purple; 18 in. across: fls. light blue, open 7 days from 9 A.M. to 6 P.M., 6–12 in. across; sepals pure green; petals 18–50, dark blue at tip, shading to nearly white at base; stamens 350–750; filaments mostly filiform; anthers bright yellow. Austral. B.M. 4647. F.S. 7:751. G.C. III. 28:77; 34:63; 53:422 (var. *Hudsoniana*). Gn. W. 20, suppl. Sept. 5 (var. *Hudsonii*). G.W. 1:122; 9:447; 15:511. Gn. 64, p. 114 (var. *Hudsonii*).—The most delicate and lovely, and withal one of the largest of the genus. The original large-flowering type (sometimes called var. *Hoòkeri*) is difficult to cult. The form now in gardens is smaller and easier to manage; it is called by Henkel *N. Caspáryi*, and in Austral. is sometimes called *N. grácilis*. White and pink forms (*N. álba* and *N. ròsea*, Benth. & Muell.) occur in Austral. An English var. *Hudsoniàna*, said to be a cross with *N. stellata* is evidently only a seedling of *N. gigantea*.

2. **violàcea,** Lehm. (incl. *N. Hòltzei*, Rehn. & Henk. *N. Rehneltiàna*, Henk. *N. Bròwnii*, Bailey. *N. Bánksii*, Cunn. *N. serràta*, Muell. *N. repánda*, Muell.). Smaller: sepals marked with black lines: lvs. wavy margined or almost entire. Cape York Peninsula.—A beautiful white form of this is called "Eleonore." A very small white one from Arnheim's Land was misnamed *N. tetragòna* by Baron von Mueller.

SUBGENUS II. BRACHYCERAS.

A. *Lvs. entire or slightly wavy at base.*

3. **élegans,** Hook. (*C. élegans*, Greene). Fig. 2551. Lvs. narrowly peltate, orbicular to ovate; margin entire or with 5 or 6 small scattered teeth; under surface dark purple; 7 in. across: fls. pale violet; 3–6 in. across, open 3 days from 8 A.M. to 1 P.M.; buds ovate; sepals marked with black lines and dots; petals ovate, obtuse, 12–20; stamens stout, about 75, yellow; appendage a mere tip; filaments broad. Mex., Texas. B.M. 4604. J.F. 2:180. G.F. 8:206 (adapted in Fig. 2551).

4. **cærùlea,** Sav. (*C. cærùlea*, Woodv. & Wood. *N. stellàta*, Casp., etc.). Blue Lotus of Egypt. Lvs. narrowly peltate, oval, entire or slightly sinuate at base; under surface green, with dark purple blotches, purplish at margin, 12–16 in. across: fls. 3–6 in. across, open 3 days from 7.30 A.M. to 12 M.; buds conical; sepals thickly marked with black lines and dots; petals 14–20, lanceolate, acute, light blue above, basal half dull white; stamens 50–70; outer filaments broad, yellow; appendage long ($\frac{3}{16}$in. on outer stamens), pale blue. Egypt, N. and Cent. Afr. Ann. Mus. Paris, Vol. I (1802), p. 366 c.p. F.S. 7:653.—Free grower and bloomer but not showy. Forms occur in Afr. with pure

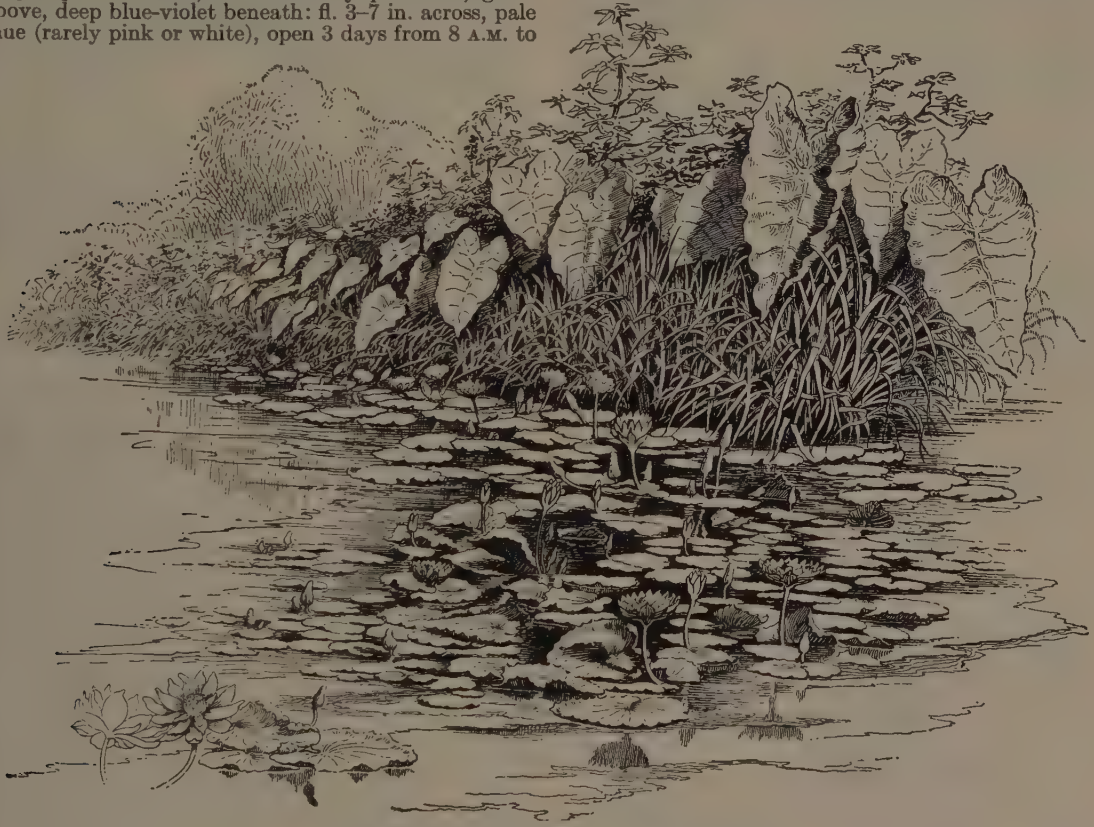
white or bright red fls., and some without spots on the calyx.

5. **micrántha**, Guill. & Perr. Lvs. elliptic, entire in apical half, rest of margin sinuate; sinus deep; lobes spreading, much produced and acuminated, bearing bulbs which produce new plants at the top of the petiole; under side of lf. green, tinged with purplish brown and minutely dotted: fls. small, white, 3–5 in. across; calyx pale green, unspotted; petals lanceolate, very acute. West coast of Afr. B.M. 4535.—*N. Daubeniàna*, Hort., intro. in 1912 by W. Tricker, is a pale blue form of this, possibly a hybrid with *N. cærulea*.

AA. *Lvs. distinctly or deeply sinuate.*

B. *Sepals marked with black dots and lines.*

6. **stellàta**, Willd. (*C. stellàta*, Woodv. & Wood, incl. *N. versicolor*, Roxbg.). BLUE LOTUS of India. Lvs. elliptic-orbicular, rather broadly peltate; margin irregularly repand-dentate; lobes scarcely produced; green above, deep blue-violet beneath: fl. 3–7 in. across, pale blue (rarely pink or white), open 3 days from 8 A.M. to 2 P.M.; buds ovate; sepals with minute blackish dots; petals 11–14, dull white at base; stamens 33–54; appendage blue; anthers and filaments pale yellowish. S. and E. Asia. Andr. Bot. Rep. 5:330. B.M. 1189 (pink); 2058. R.H. 1855:261. F.S. 8:854. Gn. 54, p. 97; 56, p. 277. G.M. 41:607.—White and pink forms occur in India.



2550. Nympheas in an effective and natural setting.

7. **ámpla**, DC. (*C. ámpla*, Salisb.). Lvs. narrowly peltate, suborbicular, sinuate or nearly entire, with small black spots above and below, 6–15 in. across: fls. white, 3–8 in. across; sepals coriaceous, ovate-lanceolate, acute; petals 7–21, lance-ovate; stamens 30–190, outermost ones much longer than innermost. Texas, south to W. Indies and Brazil. Fl. Brasil. 77:129, pl. 28–30. B.M. 4469.—Very near kin to *N. gracilis* and *N. flavovirens*. Vars. **speciòsa** and **pulchélla** are medium- and small-sized forms. Var. **Gerardiàna**, Hort. Fls. raised above water, very large, white and yellow anthers.

Two garden hybrids may be described here: *N. pulchérrima*, Tricker (N. cærulea × N. capensis?). Lvs. somewhat peltate, orbicular-ovate, strongly sinuate, angle of lobes acuminate; under surface green, densely blotched with purplish black; margin purplish red; 16 in. across: fls. light blue, 10–12 in. across; buds sharply conical; petals 22, lance-ovate, whitish at base; stamens about 140, appendaged. G.C. III. 28:273. G.M. 55:703.—*N. pennsylvània*. Conard (N. cærulea × N. zanzibariensis). Fls. large, deeper blue, open from 8 A.M. to 5 P.M.; petals 23; stamens 140.—The best blue in this group.

BB. *Sepals without black markings.*

8. **capénsis**, Thunb. (*N. scutifòlia*, DC. *N. cærùlea* of B.M. 552). CAPE BLUE WATER-LILY. Lvs. rather narrowly peltate, orbicular-ovate, strongly sinuate-dentate; angle of lobes produced, acuminate; 12–16 in across: fls. rich sky-blue, 6–8 in. across; open 4 days from 7 A.M. to 4 P.M.; buds ovate; sepals pure green outside, whitish within; petals 20–30, lower third nearly white, narrowly elliptic; stamens about 150; filaments yellow, outermost ones broad, innermost filiform; appendage and back of outer anthers blue. S. Afr. Andr. Bot. Rep. pl. 197. F.S. 6:645.—A very desirable species.

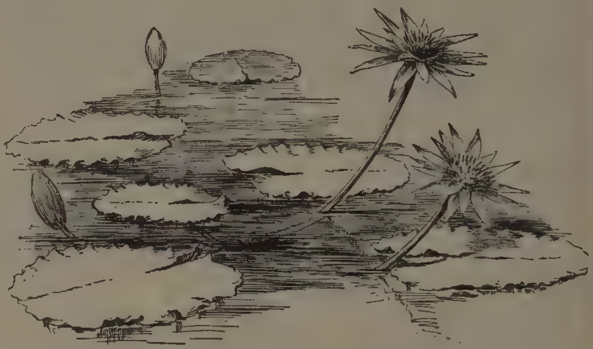
9. Var. **zanzibariénsis**, Casp. (*N. zanzibariénsis*, Casp.). Lvs. somewhat peltate, orbicular or orbicular-ovate, margin closely sinuate-dentate; angle of lobes scarcely pointed; under surface more or less suffused violet; 8–15 in. across: fl. 6–12 in. across, open 3–5 days from 11 A.M. to 5 P.M.; sepals green outside, margins purple, deep purplish blue within; petals 18–24, oblong, obtuse, deep blue; stamens 136–242, appendage dark blue; back of anther dark crimson-violet; outer filaments obovate and yellow. Zanzibar. B.M. 6843. Gn

25:210. R.H. 1897, p. 328. Var. **azùrea,** light blue, and var. **ròsea,** pink, are otherwise like the type, but open earlier in the morning; they come up promiscuously from seed of the type or of one another.—As now cult., the var. *zanzibariensis* shows the greatest variation in color of sepals and petals, as well as in shape and number of petals and stamens. The petals vary from obovate to elliptic-lanceolate. Colors shade from the deep purplish blue of the type to pale azure on one hand, or to purple, pink, and almost red on the other. The inner surface of the sepals varies from greenish white to almost pure white, or shaded toward the tip with pink, red, pale blue, or deep blue-purple. All combinations of sepal and petal coloring occur, apparently without any correlation. Many of these forms have been named, e.g., Amethyst, L. Dittmann, Kobald, Countess of Warwick, Lord Brooks, *N. Lísterii, N. z. violàcea, N. z. cœléstina,* etc. They can be reproduced true only by offsets. A small percentage of seedlings resemble the parents.

10. × **berolìna,** Hort. (*N. capénsis* × *N. zanzibariénsis? N. stellàta,* Berlin variety). Lvs. somewhat peltate, orbicular-ovate, strongly sinuate, angle of lobes acuminate; under surface dark purple; 8–16 in. across: fls. deep blue, open 3–5 days, from 9 A.M. to 4 or 5 P.M., 6–8 in. across; sepals green outside, blue within; petals 15–20, narrow, acute; stamens 60–100; appendage blue.—Free bloomer, strong grower; sterile. Originated many years ago in Germany, probably with Caspary.

11. **flàvo-vìrens,** Lehm. (*N. grácilis* of gardens, not Zucc.). Fig. 2552. Lvs. narrowly peltate, deeply and irregularly sinuate or nearly entire, suborbicular; angle of lobes rounded; under surface pure green (or purplish in hybrids); 15–17 in. across: fls. white, 6–8 in. across; sepals pure green; petals 16–20, acuminate; stamens about 60, deep yellow; outermost filaments short, broad, petaloid; anthers with long yellowish appendage. Mex. —Crossed with *N. capensis* var. *zanzibariensis,* this species has yielded a progeny showing much the same variation as is shown by *N. zanzibariensis* itself. These are distinguished from forms of the latter by their more slender and acute petals and sepals, and smaller number of floral parts. They propagate easily from the tubers, bloom very freely, and include the best of the tender, day-blooming nympheas. The deepest blue is Grossherzog Ernst Ludwig; Wm. Stone is bright blue; Mrs. C. W. Ward, pink; *N. gracilis rubra,* red. Several other named forms have been offered, e.g., Antoine Chaize, A. Siebert, *N. gracilis rosea.*

2551 Nymphæa elegans. A blue Mexican water-lily.



2552. Nymphæa flavo-virens.

Of other members of Brachyceras, the following should be mentioned: *N. Heudelótii,* Planch. Fl. 2–2½ in. across, pale blue: lvs. 2–4 in. Senegambia.—*N. calliántha,* Conard. Fl. 4–7 in. across, blue or pink: lvs. 6–12 in. Cent. Afr.—*N. sulfùrea,* Gilg. Fl. 2–3 in. across, cadmium-yellow: lf. 2–3 in. S. Cent. Afr.—*N. Stuhlmánnii,* Schw. Fl. 5–6 in. across, sulfur-yellow: lf. 10–12 in. Cent. Afr. The origin and relations of the true N. gracilis, Zucc., are uncertain; it is not in cult.

SECTION II. SYNCARPLÆ.

SUBGENUS III. CASTALIA.

A. *Fls. yellow (Xanthantha and hybrids).*

B. *Spreading by runners (natural species).*

12. **mexicàna,** Zucc. (*C. mexicàna,* Coulter. *N. flàva,* Leitner). Floating lvs. ovate, margin obscurely and finely sinuate, dark green above, beautifully blotched with brown; under surface dark crimson-brown, with small blackish dots; when crowded the lvs. rise 3–5 in. above the water, are orbicular, cup-shaped by overlapping of the straight sinus-margins, entire, 3–5 in. across, dark green and shining above, under surface bright green, with fine purplish brown mottlings: fls. 4 in. across, raised 4–5 in. above the water, bright canary-yellow, open from 11 A.M. to 4 P.M.; petals 23, grading in size and shape insensibly into the stamens, which are about 50, light golden yellow: rhizome erect, tuber-like, discoid, plane beneath, 3–5 in. diam.; runners terete, ½in. thick, white, rooting at the tip and sending up lvs.; the young plant flowers in a few weeks and again sends out runners. Fla., Mex. B.M. 6917. Gn. 23:334; 27, p. 439; 52:445.—Hardy as far north as New York "in 2 ft. of water, covered with boards and a few leaves." Mexican stock is stronger and blooms more freely than that from Fla. Rose considers them distinct species.

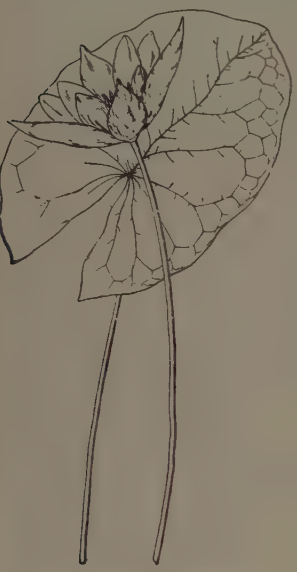
BB. *Without runners (hybrids).*

13. × **odoràta** var. **sulphùrea** (*N. sulphùrea,* Hort.). Lvs. all floating, 4–6 in. across, like those of *N. odorata,* but blotched with brown: fls. light yellow, 4–5 in. across, borne 2–4 in. above the water; open during the morning. One of Marliac's hybrids, doubtless *N. mexicana* × *N. odorata.* Hardy.—*N. odoràta sulphùrea grandiflòra* is a more recent and stronger-growing strain. G.L. 24:57.

14. × **tetragòna** var. **hélvola** (*N. hélvola* or *N. pýgmæa hélvola*). Lvs. floating, oval, 3–4 in. across, similar in shape to those of *N. tetragona,* blotched all over with brown: fls. floating, small, yellow, 2 in. across, open during the afternoon.—Probably *N. mexicana* × *N. tetragona.* Hardy.

15. ×**Marliàcea var. chromatélla** (*N. chromatélla*). Floating lvs. orbicular, much blotched with brown, 3–8 in. across; when crowded, the lvs. rise as much as 8 in. above the water, are dark green above, lighter beneath; petioles sometimes with longitudinal brown stripes: fls. bright yellow, 3–6 in. across; petals numerous, broad, concave; stamens deep yellow.—Probably *N. mexicana* ×*N. alba* (or *N. tuberosa*). Strong grower, free bloomer; a general favorite; perfectly hardy.

N. Moòrei (*N. Mooreàna*) is very similar to *N. chromatella;* believed to be *N. alba* × *N. mexicana.* —Probably as second or third hybrids of *N. mexicana* may be placed here Paul Hariot, clear yellow with delicate shadings of red at base of petals, and Sioux, rich brassy yellow, shaded red. Both have lvs. spotted reddish brown. They show some inheritance from *N. alba* var. *rubra* (see No. 28).



2553. Nymphæa tetragona.
(×½)

AA. *Fls. white, rosy or red.*

B. *Rhizome erect: fls. white (Chamænymphæa).*

16. **tetragòna**, Georgi (*C. tetragòna*, Lawson. *N. pýgmæa*, Ait.). Fig. 2553. Lvs. horseshoe-shape, entire, the lobes diverging, slightly produced and subacute, dark green above, inclined to brown blotching, reddish beneath, 3–4 in. across: fls. 1½–2½ in. across, open on 3 or 4 days from noon until 5 P.M..; base of fl. square; petals 13–17; stamens about 40, yellow. E. Siberia, China and Japan; also in N. Idaho and Ont. B.M. 1525. G.F. 9:134 (adapted in Fig. 2553).—The smallest nymphea in cult.; free bloomer; makes no side-shoots from the single crown, but grows readily from seed. Seed next to the largest of the genus. *N. fénnica*, Mela, is a form from Finland, and is offered by M. P. Andersen, Jönkoping, Sweden. It runs into purple-fld. varieties. Similar to *N. tetragona* and probably not botanically distinct. Requires cold water. *N. vomerénse* is a small white water-lily, said to be *N. alba* × *N. tetragona. N. orientàlis*, is a miniature plant with shining coppery green lvs. Japan. *N. himalayénsis*, is smaller than the type. Himalayas.

BB. *Rhizome horizontal, or, if not, fls. pink or red (Eucastalia).*

C. *Lvs. scattered loosely on the rhizome.*

17. **odoràta**, Ait. (*C. odoràta*, Woodv. & Wood). SWEET-SCENTED WATER-LILY. Lvs. nearly orbicular, entire, somewhat coriaceous, dark green above, purplish red when young; under surface deep red to reddish green or almost pure green; diam. 5–10 in.; lobes usually diverging, but often touching or slightly overlapping; petioles greenish or brownish: fls. (in the type) white, 3–5 in. across, open 3 days from 6 A.M. till 12 M.; sepals green, tinged with reddish brown; petals 23–32, ovate to lance-ovate; stamens 55–113, yellow; outer filaments broad, white, petaloid; seed medium-sized. E. U. S., common. B.M. 819 (small). Gn. 4, p. 368; 55, p. 179. V. 2:196; 19:9.—Varies greatly in size and color, approaching *N. tuberosa*. Garden forms selected for size of fl. are called var. **supérba** (*N. supérba*, Hort.) and **N. láctea.**

18. Var. **mìnor,** Sims (*C. odoràta* var. *mìnor*, Cock. *N. pùmila*). Lvs. deep red beneath (or green when aërial); lobes diverging; diam. 2–5 in.: fls. white, 2¼–3¼ in. across; sepals strongly purple-colored; petals 17–24; stamens 37–78. Same range as type; often a shy bloomer. B.M. 1652. A.G. 14: 112.—Sometimes grows where water recedes entirely in summer; usually in shallow water. N. Union is a garden form.

19. Var. **ròsea,** Pursh (*C. odoràta* var. *ròsea*, Brit. Var. *rùbra*, Hort.). CAPE COD WATER-LILY. Lvs. dark reddish on both sides when young, becoming green above: fls. pink, fading on the successive days of opening, 4 in. across. Cape Cod, Mass. B.M. 6708 (too pale). Var. **exquísita** is deeper in color of fl. and lf., and more easily grown. Vars. *rosàcea, Jessieàna* and *Hermòsa* are forms of var. *rosea.*

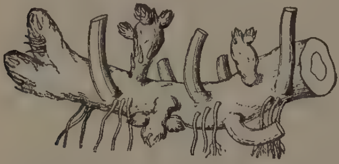
20. Var. **gigantèa,** Tricker (*C. odoràta* var. *gigantèa*, Fern.). RICE-FIELD WATER-LILY. Lvs. large, 12–16 in. across, green beneath, at times tinged purplish toward margin; edge often turned up; petioles green: fls. 4–7 in. across, pure white; sepals green; petals 24–31; stamens 69–120. Del. to Fla., Mex., Cuba, Brit. Guiana. —In this may be included *N. odoràta latifòlia*, Harper, *N. ebúrnea, N. caroliniàna nívea, N. gracíllima álba,* and *N. Parkeriàna*, Lehm.

21. × **caroliniàna,** Hort. (*N. odoràta caroliniàna* or *carolinénsis. N. odoràta supérba*, Rich. *N. tuberòsa supérba*). Lvs. entire, 12 in. across, sinus barely closed; green above, red beneath: fls. fragrant, 7 in. across; petals narrow, abundant, delicate rosy pink: rhizome stout.—Believed to be *N. odorata rosea* × *N. tuberosa.* The original type has given place to improved forms, such as *N. caroliniana perfecta, N. rosea,* and *N. salmonea* (*N. odorata perfecta* and *N. o. salmonea*), *N. odorata Luciana* (*N. Luciana*), *N. odorata suavissima* (*N. suavissima*), *N. odorata delicata, N. odorata turicensis,* and quite recently W. B. Shaw and Eugenia de Land. *N. Brakeleyi rosea* (*N. tuberosa rosea*) and *N. speciosa*

2554. Nymphæa tuberosa.
(×¾). No. 22.

belong here. *N. tuberosa* var. *rubra* of Sturtevant is a red form of this type, probably (*N. odorata rosea* × *N. tuberosa*) × *N. alba rubra*.

22. **tuberòsa,** Paine (*C. tuberòsa*, Greene. *N. renifórmis*, Walt.?). Figs. 2554, 2555. Distinguished from No. 17 chiefly by the numerous slenderly attached and spontaneously separating tubers, 1–3 in. long on the rhizome: lvs. when floating less coriaceous than in No. 17, and more veiny above; petioles marked with longitudinal brown stripes; no purple or red color about lvs. or sepals: fls. 4–9 in. across, pure white, open 3 or 4 days from 8 A.M. to 1 P.M.; petals broad, concave; seeds large (.44 cm. long). N. Cent. U. S. G.F. 1:366 (adapted in Fig. 2555), 367; 6:416 (good). Gn. 21:130; 52, p. 444. B.M. 6536 (poor).—A luxuriant grower; when crowded or in shallow water the lvs. and fls. rise 4–6 in. above the water; spreads rapidly by tubers. Moderate bloomer. Garden forms are *N. tuberosa robusta* and Helen Fowler. Var. **Richardsònii** (= var. *plèna*) has many more petals than the type. R.B. 40:101. Var. **máxima** (*N. odoràta máxima*, Hort.) is a form with round lvs. and closed sinus, the lobes curved out at the apex to a short point; petioles pubescent, with long hairs, with a few faint longitudinal brown stripes: fls. medium to large, pure white, somewhat cup-shaped. Lake Hopatkong, N. J.—Rather smaller than the type; possibly *N. tuberosa* × *N. odorata*. A diminutive form of *N. tuberosa* occurs near Trenton, N. J.



2555. Rootstock of Nymphæa tuberosa.

CC. *Lvs. crowded on the rhizomes; European species and hybrids.*

D. *Foliage green or reddish, not spotted with brown.*

23. **cándida,** Presl (*N. biradiàta*, Somm. *N. semiapérta*, Klinggraef. *N. álba mìnor*, DC. *N. nítida*, Sims?). Similar to No. 24: line of insertion of the sepals angular, projecting downward: lowest pair of veins of lf. (veins of the lobes) curved toward one another: all of the filaments broader than their anthers: fr. ovoid; seed large. Cent. and N. Eu.

24. **álba,** Presl (*C. álba*, Woodv. & Wood). Lvs. roundish, entire, floating, 4–12 in. across, red when very young; lowest pair of veins straight and diverging: rhizome black: fls. white (in the type), 4–5 in. across, open from 7 A.M. to 4 P.M.; petals broad, ovate, somewhat concave; angles of attachment of sepals rounded; filaments of innermost stamens not wider than the anthers: fr. more or less spherical; seed small. Eu. and N. Afr.—A robust species. In gardens, vars. called Albatross, *Harrisiàna*, Hermine, *delicàta* and *spléndens* may be found. Var. **candidíssima** (var. *máxima*, var. *pleníssima*) has lvs. orbicular, lobes strongly curved, overlapping, yellowish when very young: rhizome brownish, sometimes 3 in. through: fls. large, pure white, sterile.—The first nymphea to bloom in spring, continuing until frost. Very robust; a most desirable white variety.

25. Var. **rùbra,** Lönnr. (*C. álba rùbra*, Lönnr. *N. álba ròsea*, Hartm. *N. álba purpùrea*, Fries. *N. álba sphærocárpa rùbra*, Casp. *N. Caspáryi*, Carr.). Outermost petals rosy, intermediate intensely rosy, innermost deep carmine-red; anthers and stigma yellow; filaments and styles orange to deep red-brown; variable in depth and purity of color, deepening on second and third days of flowering. Lake Faver, Sweden. B.M. 6736 (stamens poor). R.H. 1879:230.—Difficult to grow, requiring cool water and subdued sunlight. About 15 named red water-lilies must be classed as forms of this variety. Var. **Froebélii** is the oldest of these and least adapted to cult. Jas. Brydon, *N. gloriòsa*, Wm. Falconer and *N. atropurpùrea* are favorites. See also No. 27.

26. **álba × odoràta ròsea.** Fls. large, cup-shaped, often raised above the water; petals broad, concave: lvs. large, dark green or purplish, rising above the water when crowded.—Robust, free-flowering plants, the color growing paler as the fl. ages; sterile. Three groups may be distinguished: (1) Fl. nearly white, flushed with rose; *N. Marliàcea álbida* (Gn. 78, p. 373), almost white; *N. Gladstoniàna*, white; Goliath and *N. lusitána*, very large, rosy. (2) Fl. light pink; *N. Marliàcea cárnea*, flesh-color; Wm. Doogue, Mark Hanna, *N. colóssea* (G. 34:609. G.M. 56:595). Leviathan, *N. somptuòsa* are very large forms, and very satisfactory. (3) Fl. rose-color; *N. Marliàcea ròsea*, *N. nobilíssima*, James Hudson.

DD. *Foliage more or less flecked with brown.*

E. *Petals never tinted yellow; color deepening with age of fl.*

27. **álba rùbra × tetragòna.** Rootstock usually erect and unbranched: lvs. small to medium size, dark green above with irregular brown spots: fls. small to medium size, pink or red.—Several garden forms, differing in size and color of fl., belong here: *N. Laydékeri ròsea*, fls. 2–3 in. across, pink changing to deep rose, opening about 11 A.M.; *N. Laydékeri ròsea prolífera*, a many-headed form. Of similar character, but larger in lf. and fl. (3–5 in. across) and colors from red to deep crimson are *N. Laydékeri lilàcea*, *N. L. fúlgens*, *N. L. lùcida*, *N. L. purpùrea*, *N. L. rùbra*, *N. Marliàcea ígnea*, *N. M. flámmea*, *N. M. rùbra punctàta*, *N. sanguínea*, *N. Ellisiàna*, Arethusa, Jas. Gurney, Jas. Brydon, Wm. Falconer, Mrs. Richmond.

EE. *Petals, especially the outer ones, more or less yellow.*

28. **álba rùbra × mexicàna.** Rhizomes erect: lvs. medium size (5–8 in.), brown-blotched: fls. 3–5 in. across, light yellow with pink center to orange, or red with yellowish tips and margins; the red color deepens as the fl. grows older. *N. Róbinsonii* is recognized by a notch midway of the sinus of the lf. *N. Seignorétii*, *N. Andreàna*, *N. auròra*, *N. chrysántha*, and *N. Laydékeri fúlva* are the older members of this group. With larger fls. and clearer colors are the recent N. Indiana, Comanche, Sioux, *N. solfatàre*, *N. graziélla*, Phebus, Phœnix, Paul Hariot. In this group may be placed Arc-en-ciel, Jean Forestier, *N. formòsa*, *N. punícea*.

2556. Nymphæa Lotus.

Redrawn from the old figure in Botanical Magazine (1804), showing an historical picture of the true white Egyptian lotus.

SUBGENUS IV. LOTOS.

A. *Fls. white.*

29. **Lòtus,** Linn. (*C. Lòtus,* Woodv. & Wood. *N. edùlis,* DC. *N. thermàlis,* DC., of the hot springs of Hungary). WHITE LOTUS. Fig. 2556. Lvs. orbicular, dark green above, under surface brownish, smooth or slightly pubescent; diam. 12–20 in.: fl. white, the broad outer petals suffused pink, 5–10 in. across, open 7.30 P.M. to 11 A.M.; sepals pure green; petals concave, broad, 19 or 20; stamens 96–103, yellow; anthers shorter than the filaments. Egypt. B.M. 797. F.S. 7:706, 707. G.F. 2:173. J.H. III. 67:497.—To this species may be assigned the garden forms *N. thermàlis* with broad petals and cup-shaped fls. from the hot springs of Grosswardein, Hungary; and the probable hybrids N. *dentàto-lòtus, N. eastonénsis* and Jubilee.

30. Var. **dentàta,** Schum. & Thonn. (*N. Ortgiesiàna,* Planch.). Lvs. glabrous or somewhat puberulent beneath: fls. pure white, 8–10 in. across, open until 1 P.M.; petals narrower than in the type, ovate, opening out horizontal; anthers longer than the filaments. Cent. Afr., Sierra Leone. B.M. 4257. F.S. 627, 628. A.G. 15:366.—*N. dentàta grandiflòra, N. d. magnífica,* and *N. d. supérba* are large and floriferous forms.

31. **pubéscens,** Willd. Lvs. ovate, 10–12 in. long, dark green above, dull purplish green and more or less pubescent beneath: fls. small to medium size, white; petals ovate, inner ones narrow; stamens inserted some distance above petals. India to Java and the Philippines.—Not cult.

32. **Zénkeri,** Gilg. Lvs. suborbicular, deeply triangular-excised, repand-dentate, thin and membranaceous, 5 in. across, pilose beneath: fls. 2½–3 in. across; petals 7–8, ovate-lanceolate, acute. Cameroon.—A very distinct dwarf form, cult. in Germany; probably not grown here.

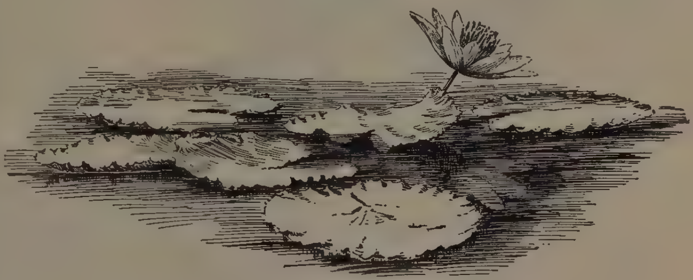
AA. *Fls. pink or red.*

33. **rùbra,** Roxbg. Lvs. orbiculate, reddish brown, bronzy, becoming greenish, pubescent beneath, 12–18 in. across: fls. deep purplish red, 6–10 in. across, open 3 or 4 nights from 8 P.M. to 11 A.M.; sepals dull purplish red, 7-nerved, never opening more than 10° above horizontal; petals 12–20, narrowly oval, rounded at apex; stamens about 55, cinnabar-red in color, becoming brownish. India. B.M. 1280. F.S. 6:629. R.H. 1879, pp. 74, 75. P.M. 11:265.—This species varies much in color, and produces fertile hybrids with *N Lotus* and *N. L. dentata.* There are, therefore, a series of garden forms of all colors from delicate pink to deep purplish crimson. In these the petals vary from broadly ovate and concave to narrowly ovate and flat, and the fls. are from tulip-shape to wide open. Some are highly floriferous, others shy bloomers. Most of these are arranged in order of color: fls. very delicate pink: *N. Smithiàna,* petals broad; *N. índica Isis, N. Laèlia, N. L. cólorans.* Fls. light pink: *N. delicatíssima, N. Deaniàna,* more pink, petals broad; *N. Boucheàna, N. índica Spìra, Reine d'Italie.* Fls. rosy pink: *N. kewénsis* (C. L. A. 25, March, p. 35), *N. Micheliàna.* Fls. red-pink: *N. Sturtevántii,* fl. tulip-shape, very massive; *N. rubicúnda,* Hofgartner Graebner. Fls. magenta: *N. Omaràna,* fl. wide open, narrow petal; *N. Ortgesiàno-rùbra, N. Màriæ-Legràngei, N. Bissétii,* Adele, Niobe, *N. tulipífera,* small, tulip-shape. Fls. rosy carmine: Diana, *N. índica Brahma, N. rùbra ròsea* (B.M. 1364), *N. devoniénsis* (B.M. 4665), Fig. 2557, *N. Arnoldiàna,* Pres. Girard. Fls. carmine: *N. Krumbiegélii, N. columbiàna, N. Diana grandiflòra.* Fls. dark red: *N. purpùrea,* Doctor Florenze, Geo. Huster. Fls. crimson to deep purplish crimson: Frank Trelease, Rufus J. Lackland, James Gurney, Jr.

SUBGENUS V. HYDROCALLIS.

34. **amazònum,** Mart. & Zucc. Lvs. ovate, entire; lobes rounded; upper and lower surfaces spotted brownish or blackish, under surface reddish brown; petiole with a ring of long hairs at the point of joining the lf.: fls. 3–6 in. across, imperfectly open 1 or 2 nights; the bud opens about half and closes again between 3 and 6 A.M. the first night; the second night the sepals and outer row of petals open about 7 P.M., the other parts remaining as a tight, white bud until 3.30 A.M., when the fl. opens fully from 4.30–5 A.M., then closes by 6.30 A.M. and draws down into the water; petals usually 20; stamens 93–297. Trop. Amer. B.M. 4823.

35. **Rudgeàna,** G. F. W. Mey. Lvs. elliptic to suborbicular, 18 in. long, margin coarsely and irregularly sinuate-dentate: fls. 3–6 in. across, imperfectly open 2 or 3 nights from twilight until dawn; usually only the sepals and 4, 8 or 12 outer petals open, the remaining parts forming a closed ovoid bud; occasionally a slight aperture is formed by drawing apart of the tip of the bud, which occurs before midnight; petals usually 16–20; stamens 43–83. Trop. Amer.



2557. **Nymphæa devoniensis.** ($\times\frac{1}{20}$). Under No. 33.

36. **blánda,** G.F.W. Mey. (Not *N. blánda,* Planch., nor of gardens). Lvs. small, membranous, entire, suborbicular; lobes slightly produced, subacuminate and subhastate: fls. 4 in. across; habits of opening unknown; petals 16; stamens about 65. Trop. Amer.

In the Hydrocallis group are the following, known only in herbaria: *N. lasiophýlla,* Mart. & Zucc. Bahia, Brazil; *N. Gardneriàna,* Planch. S. Brazil; *N. Jamesoniàna,* Planch., Porto Rico and Ecuador; *N. stenaspidòta,* Casp., Goyaz, Brazil; *N. tenerinérvia,* Casp., Bahia, Brazil; *N. oxypétala,* Planch., Ecuador; *N. Gibértii,* Morong, Paraguay.

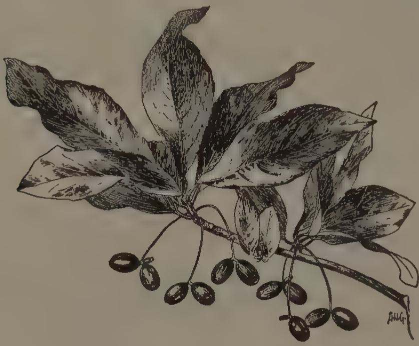
Other nympheas occasionally met with are: *N. Baùmii,* Rehn. & Henk., the smallest species known: fls. ¾–1 in. across, white, slightly fragrant. S. W. Trop. Afr.—*N. eastonénsis*=N. Smithiana × N. O'Marana.—*N. Henkeliàna,* Rehn. & Henk. Fls. strikingly flat, pale blue, having an odor of violets. Austral.—*N. Màynardii,* Hort. "Fls. fully 9 in. across, of a lovely pale shade of heliotrope."—*N. virginàlis,* Hort. Lvs. very large: fls. pure white, up to 11 in. across. Of garden origin.

HENRY S. CONARD.

NYMPHOÌDES (*Nymphæa-like*). Syn. *Limnánthemum. Gentianàceæ.* FLOATING-HEART. Ornamental aquatic herbs.

Perennial, fibrous-rooted, stoloniferous or proliferous, with floating foliage: lvs. ovate or orbiculate, heart-shaped at the base, rarely peltate, with a closed sinus, entire or slightly wavy: peduncles with 1, 2 or many fls.; fls. white or yellow, in spring and summer, borne in the axils or on filiform sts. apparently from the petioles; corolla wheel-shaped, deeply 5-cut; lobes fringed or not; stamens 5, fixed at the base of the corolla.—Species about 20 in fresh water, in tropical and subtropical regions around the world and reaching into temperate parts. The generic name is in dispute, it having been known heretofore as Limnanthemum. This genus and a very few others are sometimes separated in the family Menyanthaceæ, distinguished from Gentianaceæ in habit, in alternate or basal lvs., and different æstivation.

The floating-hearts of cultivation are most useful ornamental aquatic plants, and are represented in cultivation by but four species. *Nymphoides lacunosum* is hardiest of American species; its mottled, variegated leaves, about 2 inches broad, are very attractive, regardless of its dainty, white, miniature flowers. It is best grown under natural conditions, in pools and still water, and in water about 2 feet deep. It may also be grown in tubs, as a surface covering, with a few tall plants in the center. *N. aquaticum*, commonly known as the fairy water-lily, is a much stronger grower: leaves deep green, and, when grown in natural ponds, attain large proportions, 4 to 6 inches broad, and bears innumerable flowers, more like flakes of snow. It is also valuable for tub culture, similar to the preceding species *N. indicum*, commonly called water snowflake, is undoubtedly the most interesting and attractive of any, and deserving of most general cultivation. The leaves are of a light green color, heart-shaped, and it produces flowers in greater abundance, which are much larger and covered completely with hirsute glands. These, as in the other species, are produced in clusters on the petioles, near the surface, and, although they are of but one day's duration, they are produced in such quantities that there is never any lack of these delicate flowers all through the season. In tub culture, this species will soon crowd itself over the edge of an ordinary tub, and, although the leaves no longer float on the surface, it does not affect the growth or the proliferousness of its flowering. When grown in tubs, the receptacle should be filled two-thirds with moderately rich, loamy soil, covered with sand, and filled and kept filled with water. All three species, when strong enough to produce flowering leaves or petioles, send forth new shoots, as each cluster of flowers apparently terminates with a bud and produces leaves; these, when strong, produce flower-buds and leaf-buds again, and thus soon reproduce themselves. *N. aquaticum* produces a cluster of fleshy roots, with a bud from single leaves in fall, which are plentiful in Florida in the season. These are excellent for distribution, and can be sent safely a great distance. The petioles are very brittle and easily snap off, but the floating leaf soon emits roots at the broken end as well as where the flower-buds are located; thus it is very free and proliferous. These are very desirable aquatic plants. The fourth species, *N. peltatum*, is a rampant, weedy plant, although its mottled foliage is beautiful and the flower is much larger than those of the above plants. Its habit of growth is also different. it produces runners, and rambles over an immense space; it also produces seed in great quantity, which, when ripe, floats on the surface for a short time, then sinks to the bottom; it is best confined to the limits of a tub, where it grows freely and produces its large yellow flowers in profusion. It is hard to eradicate when once established, as it is perfectly hardy. All the floating-hearts are very pretty and useful for tub culture, but after knowing the water-lilies the general public desires more bold and striking plants. (Wm. Tricker)



2558. Nyssa sylvatica. (×⅓)

A. *Color of fls. yellow.*

B. *Fls. accompanied by clusters of tubers.*

lacunòsum, Kuntze (*Limnánthemum lacunòsum*, Griseb. *Villársia lacunòsa*, Vent.). Sts. sometimes 10 ft. long: lvs. orbicular-cordate, purplish beneath, 1–2 in. long: fls. 3–6 lines across; segms. ovate, acute: seeds smooth. July, Aug. Ponds, Nova Scotia to Fla. and La., west to Minn.

BB. *Fls. not accompanied by clusters of tubers.*

peltàtum, Brit. & Rend. (*N. nymphæòides*, Brit. *Limnánthemum nymphæòides*, Hoffm. & Link. *Menyanthes nymphæòides*, Linn.). Plant stout and branching: lvs. 2–4 in. broad: fls. 1 in. across or more; segms. obcordate, short-fringed. May–July. Eu., Asia; naturalized in District of Columbia.—Simulates *Limnocharis Humboldtii* in habit.

AA. *Color of fls. white (varying to yellow in the last).*

B. *Seeds rough.*

aquáticum, Kuntze (*L. trachyspérmum*, Gray. *Villársia aquática*, Gmel.). Stouter and larger than *N. lacunosum:* lvs. cordate orbicular, thick, entire or repand, 2–6 in. long, spongy: tubers thick: fls. 6–10 lines broad. April–July. N. J. to Fla. and Texas.

BB. *Seeds smooth.*

índicum, Kuntze (*L. índicum*, Thwaites. *Menyánthes índica*, Linn.). WATER SNOWFLAKE. Fls. white, yellow toward the base within; segms. fimbriated, densely papillose, without a longitudinal fold down the middle. Tropics. Gn.M 4:182.—There is said to be a rich yellow variety.

WILHELM MILLER.
L. H. B.†

NÝSSA (name of a water nymph; these trees grow in swamps). *Nyssàceæ*, formerly included in *Cornàceæ*. TUPELO. PEPPERIDGE. SOUR GUM. Ornamental trees planted chiefly for their handsome foliage and brilliant autumnal tints.

Deciduous. lvs. alternate, petioled, entire or rarely remotely toothed, stipulate: fls. polygamo-diœcious, minute, greenish white, in slender peduncled clusters; the staminate fls. slender-pedicelled in many-fld. clusters; calyx cup-shaped, 5-toothed; petals 5, imbricate, inserted on the margin of the conspicuous disk; stamens 5, exserted; ovary 0; pistillate fls. sessile, 1 or 2, or in few-fld. clusters; calyx-tube campanulate, 5-toothed, petals small; stamens 5–10, short, anthers often sterile; ovary 1-2-celled; style slender, recurved: fr. an oblong drupe, usually 1-seeded, with a bony, ridged or winged stone.—Five species in N. Amer. and 2 in Asia.

The tupelos are bold and picturesque trees with medium-sized or rather large, generally obovate or oblong lustrous leaves, insignificant greenish white flowers in slender-stalked clusters or solitary, and conspicuous, blue, red or purple oblong solitary or paired fruits. They are chiefly valued for the flaming scarlet of their autumn foliage and for the distinctness of their winter aspect. *N. sylvatica* is hardy North, while the other species are tenderer. They grow in swamps and are usually 40 to 60 feet high, attaining a maximum of 100 feet. Old specimens often have a melancholy appearance by reason of the drooping habit of the lower limbs. The upper branches of a tupelo are often twiggy, crooked or "kinky." Tupelos are hard to transplant from the wild, even when heavily pruned, because they have remarkably long roots with few rootlets. Nursery-grown trees that have been frequently transplanted are preferable. Propagation is by seeds sown at once or stratified; if allowed to become dry, they do not germinate until the second year; sometimes increased by layers which, however, root slowly.

sylvática, Marsh. (*N. multiflòra,* Wang.). TUPELO. PEPPERIDGE. BLACK GUM. SOUR GUM. Figs. 2558,

2559. Tree, to 100 ft., with slender pendulous branches forming a flat-topped usually cylindrical head, sometimes low and broad, or in crowded trees pyramidal: lvs. usually entire, obovate or oval, mostly acute or acuminate, lustrous above, pubescent on the veins or glabrous at maturity beneath, 2–4 in. long: staminate fls. in compound heads; pistillates larger, 2 or several: fr. ⅓–⅔in. long, nearly black, acid, with an ovoid stone, little flattened. Maine and Ont. to Mich., to Fla. and Texas. G.F. 3:491; 7:275. F.E. 14, pl. 32. S.S. 5:217.

aquática, Marsh. (*N. uniflòra*, Wang. *N. denticulàta*, Ait.). Cotton Gum. Tree, occasionally to 100 ft., with small spreading branches forming a pyramidal head: lvs. slender-stalked, ovate to oblong, acute or acuminate, entire or remotely toothed, at maturity lustrous above, pubescent beneath, 5–7 in. long: pistillate fls. solitary, surrounded by 2–4 strap-shaped bractlets to ½in. long: fr. oblong, 1 in. long, dark purple. Va. to Ill. and Texas. S. S. 5:220.

N. sinénsis, Oliver. Tree, to 40 ft.: branchlets pubescent: lvs. elliptic, dull dark green above, light green and pubescent on the veins beneath, 4–6 in. long: pistillate fls. few, on slender stalk: fr oblong, bluish, ½in. long. Cent. China. H.I. 20:1964.—Has proved hardy in S. England.

Wilhelm Miller.
Alfred Rehder.†

2559. Pepperidge.—Nyssa sylvatica.

O

OAK. Plants of the genus Quercus (which see). The word is also applied to other plants to some extent, from resemblances in form of tree, in leaf, or in hardness of wood. In Australia, where there are no species of Quercus, the word oak is applied to the species of Casuarina, "from a fancied resemblance," as Maiden says, "of the wood of casuarinas to that of oak." Other plants in Australia are sometimes known as oaks. The silk oak of florists is *Grevillea robusta*. The Jerusalem oak is *Chenopodium Botrys*, probably from the shape of the leaves. Poison oak is *Rhus Toxicodendron*, and related species.

2560. The white oak.—Quercus alba.

OAKÈSIA (Wm. Oakes, New England botanist, 1799–1848). *Liliàceæ*. Three species of native perennial woods herbs, having the graceful habit of such choice wild flowers as the Solomon's seal and more particularly the common bell-wort, *Uvularia perfoliata*. *O. sessilifolia* has been offered by a few dealers in hardy plants. It prefers a rich light soil in a rather moist, partially shaded position, and improves under cultivation.

Oakesia can be easily distinguished from Uvularia by the lvs., which are merely sessile instead of perfoliate, by the angled rather than terete sts., and fls. opposite the lvs. rather than terminal. Oakesia was separated from Uvularia in 1879 by Watson. Lately the name Oakesiella has been applied to the genus because there is an earlier Oakesia (which, however, is an untenable name for Corema). By some botanists, the species are still retained in Uvularia. Other generic characters are: fls. few, solitary on short pedicels opposite the lvs.; segms. without callosities: caps. membranous, elliptical, winged, acutish at each end, very tardily dehiscent: lvs. more or less rough on the margins: seeds globose, with a tumid raphe but no aril.

sessilifòlia, Wats. (*Uvulària sessilifòlia*, Linn. *Oakesiélla sessilifòlia*, Small). St. once forked: lvs. oblong-lanceolate, acute at each end; margins minutely scabrous: caps. borne on a distinct stipe. Canada to Fla. and Ark. B.M. 1402. L.B.C. 13:1262. L. H. B.†

OAT: *Avena sativa.*

OBELISCÀRIA: *Lepachys.*

OBERÒNIA (Oberon, king of the fairies, because of the quaint flower forms). *Orchidàceæ*. Perhaps 100 tufted epiphytic orchids in Trop. Asia and Austral. and Pacific islands, little known in cult., but of much botanical interest. Lvs. distichous, ensiform or terete: fls. very small, in dense spikes or racemes, in the cult. species yellow, orange or buff; sepals free, equal or nearly so, oblong or broadly ovate, larger than the petals; lip sessile, usually concave, entire or toothed. They probably require warmhouse treatment; some of them will grow on blocks. None of the species seems to be regularly in the trade here, but odd or particular plants are sometimes offered, as *O. tahiténsis*, Lindl. (*O. iridifòlia*. B.M. 4517, not Lindl.), *O. Myosùrus*, Lindl., *O. ensifórmis*, Lindl. (*O. acaùlis*, Hook. B.M. 5056).

ÓCHNA (old Greek name for a wild pear, which some of these plants were thought to resemble in foliage). *Ochnàceæ*. Glasshouse woody plants, little grown for the odd showy bloom and fruit.

Ochna is a genus of about 25–30 species of trees and shrubs of Trop. Asia and Afr., and a few in S. Afr.: lvs. deciduous, alternate, minutely serrate, leathery, shining: fls. yellow, rarely greenish, jointed to the pedicels; sepals 5, colored, imbricate, persistent; petals 5–10; stamens indefinite; anthers opening longitudinally or by pore-like slits; ovary deeply 3–10-lobed, the lobes 1-celled, 1-ovuled, and seated around a central disk or receptacle and becoming sessile drupes, styles connate.

multiflòra, DC. Glabrous shrub, 4–5 ft. or more high: lvs. oblong-elliptical to oblanceolate-oblong: petals sessile; anthers as long as the filaments, opening longitudinally, sepals in fr. about 4 lines long. Upper

Guinea. G.C. III. 40:212. J.H. III. 44:209. G.W. 2, p. 328.—*O. multiflora* is a greenhouse shrub cult. by a few fanciers for its remarkable appearance when in fr. The fls. are yellow, appear in spring, and are borne to the number of 10–15 in racemes terminating short lateral branches. The blossoms are short-lived, but the calyx is persistent. Its 5 sepals are greenish in fl., but become a bright red in fr. The receptacle increases until it becomes an inch or so thick, globular and bright red. Upon it are borne black seedlike bodies, which are the carpels. The red and black make a fine contrast. This plant is best prop. by half-ripened cuttings struck in summer or autumn. It requires in England a winter temperature of 48–60°, and summer temperature of 60–85°; soil, fibrous loam with plenty of drainage.

O. atropurpùrea, DC., of the Cape, may occur now and then: shrub, 4–5 ft., with ovate denticulate lvs.: calyx dark purple, petals yellow; fls. on 1-fld. stalks. J.F. 1:29.

WILHELM MILLER.
L. H. B.†

OCHROCÁRPOS (Greek, *yellow fruit*). Incl. *Calysáccion*. *Guttíferæ*. Trees, of about 20 species, widespread in the tropics, little known horticulturally. Lvs. opposite or in 3's, coriaceous: fls. axillary, polygamous, the petals 4–7 or more; stamens indefinite, free or somewhat connate, the filaments slender and anthers erect; ovary 2-celled: fr. berry-like, with a few large seeds. *O. africànus*, Oliver, is a tree 40–50 ft. high: lvs. large, oblong-elliptical, with the midrib very prominent beneath: fls. from the nodes of the fallen lvs., 1½ in. diam., the petals half as long again as sepals; stamens very many: fr. very large, several inches diam., with yellow pulp. Upper Guinea. *O. obovàlis*, Safford, is the "chopag" of Guam, the wood of which is used in house-construction (p. 1699, Vol. III). It is a medium-sized tree, with opposite short-petioled obovate or oblong-obovate entire lvs. rounded at the apex, and fragrant white polygamous fls. borne laterally, single or clustered. L. H. B.

OCHRÒMA (named for the *paleness* of the fls.). *Bombacàceæ*. One tree of Trop. Amer., allied to Ceiba: lvs. simple, angled or lobed: fls. large, terminal. **O. Lagòpus**, Swartz, is listed abroad but hardly a horticultural subject: it is the corkwood or balsa of the W. Indies, from which canoes and other things are made, the wood being very light, the bark yielding fiber: tree to 40 ft. high: lvs. 5–7-lobed or only angular, nearly entire or dentate, puberulous beneath: petals 5–6 in. long, yellowish white or brownish, somewhat surpassing the column of stamens, obovate and wavy, clawed; calyx 5-lobed, subtended by a caducous involucre of 3 parts; stamens comprising a column which is topped by 1-celled anthers; stigma 5, exserted, spiral: caps. 1 in. long, 5-celled, with reddish brown wool inside. L. H. B.

OCHRÒSIA (name records the pale yellow color of the fls.). *Apocynàceæ*. Fifteen or more trees, extending from the Mascarene Isls. eastward to Hawaii, little known to cult.: lvs. scattered, whorled or opposite, with numerous nerves, coriaceous, entire, often large: fls. in peduncled cymes, of medium size, often very fragrant, mostly white, yellowish or cream-colored; calyx small, glandless, deeply 5-cleft; corolla salverform, the tube cylindrical and dilated at point of insertion of stamens, the throat constricted and glabrous; disk small or wanting: carpels 2, distinct or connate at base, ripening into spreading few-seeded or 1-seeded drupes.—The species are grown somewhat in tropical countries for the ornamental foliage and frs.

O. borbónica, Gmel., is an evergreen tree 20–30 ft., with stout branches, glabrous: lvs. large, whorled, obovate, narrowed to a petiole, rounded at apex, shining above: fls. white; corolla-limb ⅓in. diam.: drupes about 2 in. long, bright red, considered to be poisonous. Mascarene Isls. eastward.—*O. ellíptica*, Labill.=O. parviflora.—*O. parviflòra*, Hemsl. (Cerbera parviflora, Forst.), is a Pacific species, somewhat planted in Hawaii: 30–40 ft., evergreen, with rough bark and cylindrical twigs: lvs. ternate quarternate, crowded at ends of branches, oblong-lanceolate, acuminate, shining: fls. small, white: fr. 1 or 2 scarlet drupes, not edible.—*O. sandwicénsis*, Gray, of Hawaii, is a small tree or large shrub, 10–25 ft., with long drooping branches: lvs. in 3's or 4's, long-oblong, short-acuminate, shining above: fls. yellowish to cream-colored: drupes dry, yellowish at maturity, not edible.

L. H. B.

ÒCIMUM (an old Greek name). Sometimes spelled *Ocymum*. *Labiàtæ*. Sweet herbs. See *Basil*.

Annual and perennial, sometimes shrubby, with opposite lvs.: fls. mostly small and white or whitish, or yellow, usually 6 in each verticil and the verticils in terminal or paniculate racemes; calyx deflexed in fr., unequal-toothed; corolla-tube usually not exceeding the calyx, 2-lipped, the upper lip 4-lobed; stamens 4, didynamous and declined; style shortly 2-cut: nutlets ovoid or subglobose, smooth or punctate.—Species about 60, in the warmer parts of the world. Little known in cult. except in the basil, which is used as seasoning and also grown for its very pleasing fragrance. This is **O. Basílicum,** Linn., of Trop. Asia and Afr. and Pacific islands: annual, glabrous or slightly pubescent, much branched, 1–2 ft. high: lvs. petioled, ovate, entire or toothed: fls. in moderately dense racemes, white or more or less tinged purple; calyx becoming ¼in. long, and corolla ⅓–½in. long; stamens slightly exserted. **O. mínimum,** Linn., the bush basil, is probably a small cult. form of the foregoing. **O. suàve,** Willd. (*O. gratissimum* var. *suàve*, Hook.), the tree basil of India, Afr., and the E., is a shrub 4–8 ft. high, woody below and much branched, the lvs. densely soft-tomentose on both surfaces and in this differing from *O. gratissimum:* lvs. ovate, acute, crenate or coarse-toothed: corolla whitish or purple-tinged, little exceeding the calyx, the latter becoming ¼in. long: racemes dense and much panicled, becoming 6–9 in. long.

Of the common basil (*O. Basilicum*) are forms of compact habit, and others with purplish foliage; also with crimped or wavy lvs. The basils are tender and should not be trusted in the open ground until unsettled weather is passed. The plants may be started indoors, and transplanted to 6–10 in. apart in warm ground. The herbage is cut when the plant is growing, and dried in bundles; the plant, when cut off, gives a new crop if it is not exhausted and if the soil is good. Roots may be lifted for a winter supply of foliage. The very aromatic herbage is used for seasoning, and the plant was once esteemed for medicinal properties. The oil is used in the preparation of certain liquors. L. H. B.

OCTOMÈRIA (from the Greek for *eight* and *part*, referring to the pollinia). *Orchidàceæ*. Epiphytic herbs: sts. cespitose: lf. solitary, sessile or subsessile, borne at the tips of the sts.: fls. small, clustered at the base of the lvs.; sepals and petals similar, spreading; labellum shorter than the sepals, strongly 3-lobed or pandurate; column short; pollinia 8.—The following species are natives of Brazil.

arcuàta, Rolfe. Sts. somewhat slender, clothed with membranaceous sheaths: lvs. subsessile, brown-purple on both sides when mature, lanceolate, sub-recurved, fleshy: fls. bright yellow, solitary, sub-pendulous; sepals and petals oblong, obtuse; labellum recurved, lateral lobes erect, obtuse, middle lobe broadly triangular-ovate, disk bicarinate, keels and side lobes dark purple.

decípiens, Dammer. Sts. 2–3-jointed, terete, clothed with membranaceous sheaths: lf. semi-terete; fls. fasciculate, shortly pedicellate; sepals and petals ovate, the lateral sepals slightly connate at base, yellow; labellum triangular-ovate, elongated, 3-lobed; lateral lobes rounded, erect; middle lobe yellow, disk bilamellate.

Óppenheimii, Dammer. Sts. about 2 in. long: lf. ovate-lanceolate: fls. white; lateral sepals connate at base, lanceolate, acute; upper sepal lanceolate, acuminate; petals lanceolate, labellum lyrate, 3-lobed, fleshy at base, otherwise hyaline, margin irregularly denticulate, disk bicarinate. Oakes Ames.

ODONTADÈNIA (Greek, *toothed glands*). *Apocynàceæ.* Here belongs the tropical yellow-flowered climber sold as *Dipladenia Harrisii*, which rivals in beauty the well-known greenhouse allamandas.

Tall shrubby climbers or lianas: lvs. opposite: cymes loose, usually ample, rarely few-fld. and scarcely branched; calyx 5-parted, the lobes remarkably blunt or rounded; corolla-lobes twisted in the pointed bud, overlapping to the right and twisted to the left; stamens fixed at the top of the narrow part of the tube; fls. yellow, whereas those of Dipladenia are yellow only in throat if at all. The genus is further distinguished from Dipladenia by the shape of the calyx-lobes and by the cup-shaped group of toothed glands below the pistil.—Species 20–25, Trop. S. Amer. and Cent. Amer.

grandiflòra, Schum. (*O. speciòsa*, Benth. *Dipladènia Hárrisii*, Hook.). Shrubby branched climber: largest lvs. 10–15 x 4–5 in., oblong, tapering, scarcely leathery, feather-veined, often purplish beneath; petioles stout, scarcely 1 in. long: racemes axillary and terminal; pedicels red, often 1 in. long, curved downward; corolla-tube with a roundish base about ½in. long and thick, then suddenly constricted, then gradually widening into a funnel-shaped fl. Brazil, Guiana, Trinidad. B.M. 4825.—The fls. are fragrant, about 3 in. across, funnel-shaped, with 5 rounded, spreading lobes, and are more or less streaked with red in the throat, at the base of the lobes, and on the back of the tube. The treatment for dipladenias (see *Dipladenia*, Vol. II) should be attempted for Odontadenia, but *O. grandiflora* perhaps grows at lower altitudes, and may require the treatment usually given to hothouse vines.

O. nítida, Muell. Arg. (O. cordata, A. DC.) from Trop. S. Amer., is a twining glabrous shrub with yellow corolla bearing a band of vermilion below the middle of the narrow tube: lvs. oblong or elliptic, 4–6 in. long: fls. nodding on axillary pedicels, the tube narrow and constricted at the colored part, the 5 lobes broad-ovate and acute. It is referred to the genus Angadenia in B.M. 8233 (*A. nítida*, Miers), and is probably best understood when thus separated.

Wilhelm Miller.
L. H. B.†

ODONTIÒDA (compounded from *Odontoglossum* and *Cochlioda*) *Orchidàceæ.* A genus established to contain the hybrids between Odontoglossum and Cochlioda.

The following are some of these hybrids: *O. beechénse* =O. Rolfeæ × C. Noetzliana.—*O. Bóhnhóffiæ* (O. cirrhosum × C. vulcanica). Fls. blood-red, the sepals and petals narrow, marked somewhat with white, tinged slightly purple at base; lip with a yellow crest with a few red spots.—*O. Bòltonii*=O. Vuylstekeæ × C. Noetzliana.—*O. Brádshawiæ* (O. crispum × C. Noetzliana). Fls. resembling in shape those of the first parent, but smaller; sepals and petals cinnabar-scarlet; lip 3-lobed, whitish, the lobes scarlet-tipped, and a spot of the same color in front of the yellow crest. Gn. 71, p. 55. G.M. 56:337.—*O. Brèwii*=O. Harryanum × C. Charlesworthii.—*O. Chárlesworthii* (O. Harryanum × C. Noetzliana). Fls. resembling in shape those of the cochlioda, ruby-crimson, except the spiny yellow crest. Gn. 72, p. 301. J.H. III. 56:583.—*O. chelseiénsis* (O. crispum × C. vulcanica). Fls. intermediate in shape between those of the parents, compactly arranged, carmine-rose, lightly marbled with yellow on the sepals; lip light yellow, 3-lobed, the lobes tipped with carmine-rose, and a darker blotch in front of the crest. O.R. 17:48. G.M. 52:70. Gn. 73, p. 112.—*O. chessingtonénsis*=O. Rolfeæ × C. Noetzliana.—*O. Coòksoniæ*=O. ardentissimum × C. Noetzliana. O. 1913, p. 103.—*O. Corneyàna*=O. Lambeauianum × C. Noetzliana.—*O. Craveniàna* (O. cordatum × C. Noetzliana). Fls. more nearly resembling in shape those of the cochlioda; sepals and petals red; lip broad, salmon-red, white in front, and with a yellow crest. G.M. 51:25.—*O. cùprea*=O. cristatum × C. Noetzliana.—*O. daltonénsis*=O. Phœbe × C. Noetzliana.—*O. Devossiàna* (O. Edwardii × C. Noetzliana). Panicle compact; fls. crimson, the 3-lobed lip lighter at the apex, and with a yellow crest. O.R. 16:41.—*O*, *eborìacum* (origin doubtful). Fls. medium-sized. scarlet; lip with pale yellow markings.—*O. Flòryi*=O. Andersonianum × C. Noetzliana.—*O. gattonénsis*=O. Kegeljanii × C. Noetzliana.—*O. Goòdsoniæ* (origin doubtful). Fls. large, rosy red, irregularly marked with cream-color; crest of lip yellow, somewhat red-marked in front. G.C. III. 45:195. G.M. 53:302.—*O. Graireàna*=O. Rossii majus × C. Noetzliana.—*O. gràta*=O. tripudians × C. Noetzliana.—*O. heatonénsis* (O. cirrhosum × C. sanguinea). Fls. white, the sepals and petals oblong-lanceolate, suffused at the apex and spotted below with rosy purple; lip ovate, spreading, acuminate and recurved at the rosy purple apex. B.M. 8133.—*O. Hemptinneàna*=O. eximium × C. Noetzliana.—*O. Hyeànæ*=O. ardentissimum × C. Noetzliana.—*O. ígnea*=O. Lindenii × C. Noetzliana.—*O. Jéssopiæ*=O. "Queen Alexandra" × C. Noetzliana.—*O. keighleyénsis*=O. cirrhosum × C. Noetzliana.—*O. Lambeauiàna*=O. Lambeauianum × C. Noetzliana.—*O. Leeàna*=O. spectabile × C. Noetzliana.—*O. Lutètia*=O. luteo-purpureum × C. Noetzliana.—*O. maculatíssima*=O. amœnum × C. sanguinea.—*O. Móssiæ*=O. maculatum × C. Noetzliana.—*O. nevénse*=O. nevadense × C. Noetzliana.—*O. oakwoodiénsis*=Odontioda Bradshawiæ × O. percultum.—*O. rawdonénsis*=O. ardentissimum × Odontioda Charlesworthii.—*O. Rólfei*=O. Hunnewellianum × C. vulcanica.—*O. rosefieldiénsis* (O. triumphans Mr. de B. Crawshay × C. Noetzliana). Fls. scarlet, slightly shaded yellow; lip yellow, red-tinged, the basal ridges bright yellow. G.C. III. 49:308.—*O. Sánderæ*=O. percultum × C. Noetzliana.—*O. Schrœderi*=O. crispum × Odontioda Bradshawiæ.—*O. Sèymouræ*=Odiontioda Charlesworthii × Odiontioda Bradshawiæ.—*O. Sèymourii*=O. Uroskinneri × C. vulcanica.—*O. speciòsa*=(?).—*O. Thwàitesii* (O. Harryanum × C. vulcanica). Sepals and petals bronzy claret; lip lilac-purple with a yellow crest. J.H. III. 57:147.—*O. Vuylstékeæ* (O. nobile × C. Noetzliana). Fls. about 2½ in. across; sepals and petals ovate-lanceolate, with a crimson base, the upper portion white with red spots, the margin pink; lip fiddle-shaped, yellow at base, the rounded lateral lobes crimson, the rounded middle lobe white, crimson-spotted. B.M. 7990. R.B. 33:169. Gn. 65, p. 433.—*O. wickhaménsis*=O. crispum × C. sanguinea.—*O. Wílsonii*=O. Pescatorei × C. vulcanica.—*O. Zenòbia.* G.C. III. 55:226.

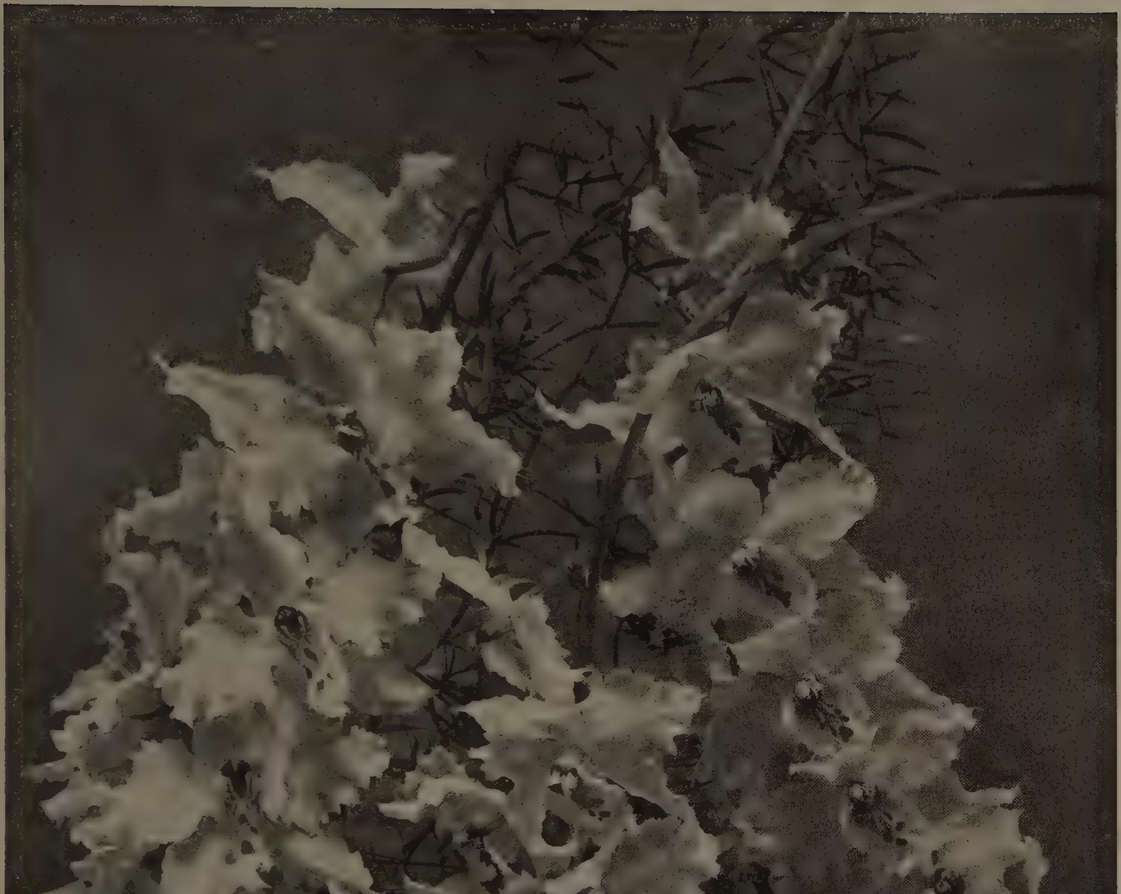
George V. Nash.

ODONTOCÍDIUM (compounded from *Odontoglossum* and *Oncidium*). *Orchidàceæ.* A genus established to contain the hybrids between Odontoglossum and Oncidium.

O. Edwardàtum=Odontoglossum Edwardii × Oncidium serratum.—*O. Fowleriànum*=Odontoglossum cirrhosum × Oncidium Forbesii. G.M. 54:878.

ODONTOGLÓSSUM (Greek, *tooth-tongue;* in allusion to the crest on the labellum). *Orchidàceæ.* Orchids which on account of their handsome flowers are great favorites of cultivators. *O. crispum* is one of the finest of all orchids.

Plants epiphytic, with short rhizomes and 2-lvd. pseudobulbs, often with sheathing lvs. at the base: fls. in few- to many-fld. racemes or panicles arising from the base of the pseudobulb; sepals and petals spreading, free, or the lateral sepals rarely somewhat united at the base; base of the labellum ascending parallel to the column and sometimes adnate to the latter; lateral lobes small, often erect; middle lobe large, spreading, variously shaped; column clavate, narrowed at the base, longer than in Oncidium.—About 100 species,



LXXVI. Odontoglossum crispum, with Asparagus Sprengeri decoration.

natives of the higher regions of the Andes from Mex. and Guatemala to Colombia, Bolivia and Peru.

This genus is closely related to Oncidium and Miltonia, some of the species of the latter being generally cultivated as odontoglossums. These two genera are easily distinguished from Odontoglossum by the labellum, which expands directly from the base of the column. There is perhaps no genus of orchids in which the species are more variable and more closely related than in Odontoglossum. Numerous varieties connect the species by intermediate links, and the occurrence of many natural hybrids makes the limitation of species in this genus almost impossible. However much this may add to the perplexity of the botanist, it gives the genus an additional horticultural value and interest resulting in the production of numerous garden hybrids and in the selection of many varieties, one species, *O. crispum*. having over a hundred named kinds.

Cultivation of odontoglossums.

Odontoglossums follow the high western mountain ranges from southern Mexico to southern Peru, and usually grow at great altitudes. With few exceptions, they are found in extremely moist situations where the annual rainfall is excessive and the temperature more or less even and cool throughout the year.

The extreme heat of our summer interferes somewhat with the culture of odontoglossums in America, especially those of the *O. crispum* section, and it is necessary to use every precaution during that season to insure success.

A lean-to or half-span roof structure of northern exposure, protected by a brick or stone wall on the south side, and with ample means of ventilation, is best suited to odontoglossum culture. Moreover, it should be provided with rolling shades elevated on framework 18 or 20 inches above the glass, to afford abundance of light, free access of air and requisite shade, with the additional assistance of keeping down the temperature in summer. The interior is best fitted with solid beds, if possible, but benches of stone flags or wood covered with ashes or gravel an inch or two deep will answer very well. These, with the floors, should be hosed down two or three times daily, to keep the house as cool and as moist as possible.

Ventilation is highly essential at all times, especially in dull or wet weather. When the atmosphere is overcharged with moisture, the quantity must be governed by outside conditions. Top ventilation is most satisfactory, because it allows the heated air to escape, gives less direct draft on the plants, and does not have the drying effect produced by side currents.

The temperature during winter should never rise above 65° F., even with mild sun heat, and may fall to 48° or 50° at night, or even lower, without injury; during summer it must be kept as low as the outside temperature will admit. Fire heat should be dispensed with as early as possible in spring.

Odontoglossums do well under pot culture, excepting a few, such as *O. Londesboroughianum* and *O. brevifolium*, with long creeping rhizomes; *O. citrosmum*, which has pendulous flower-scapes, and some of the smaller-growing species, such as the *O. Rossii* section, which are more easily cared for under basket culture.

Repotting should be attended to in October and November, never during the summer months. Chopped fibrous peat, live sphagnum and clean decayed leaves in equal quantity, well mixed together, afford a very satisfactory compost. About one-half of the pot space should be devoted to drainage of charcoal or broken potsherds. The plants should be firmly potted, leaving the surface slightly convex, thus elevating the base of the plant a little above the rim of the pot when finished.

The *O. crispum* section, which includes *O. Coradinei*, *O. gloriosum*, *O. cirrhosum*, *O. luteo-purpureum*, *O. nobile*, and kindred species, requires an abundance of water at all seasons; in fact, the compost should never dry out, and judicious light overhead syringing once a day is beneficial in bright weather, but on very warm days it should be applied in the evening, at the same time allowing free ventilation to ensure good atmospheric action. Weak liquid cow-manure during the flowering period is also of assistance.

Species of the *O. grande* section do not require so much water at the roots as the *O. crispum* type; the compost should be allowed to dry out frequently. They are also benefited by a little sun during winter. *O. citrosmum* is an exception to the genus as regards temperature, and should be grown 10° warmer. It does very well in the cattleya department, enjoys a good supply of water at the roots at all seasons, and may be easily induced to flower freely by giving it a sunny location during winter.

Very few of the species can be satisfactorily propagated by division; the trade depends principally on fresh importation, and they come readily from seeds. (See the article on *Orchids*, beginning page 2380, for discussing of seed-growing methods of orchids in general.)

Among the worst enemies of odontoglossums are slugs and the small shell snails. They destroy the tender flower-scapes, often attacking them even in the leaf-sheath. A piece of cotton wrapped about the base of the pseudobulb will afford a means of protection, and many may be caught by distributing bits of apple, potato, or saucers containing dry bran freely among the plants. Look them over in the morning or evening with a lantern.

Robert M. Grey.

Cool odontoglossums.

There has been a large measure of success attained in the culture of these Andean plants in several instances and near the seashore, or during a cool summer season. The plants do well under special conditions, such as a structure facing north, with ample shade by using roller-blinds a foot or more above the glass roof, and by using a spray of water on very hot days either under the benches or in the path, ejected with force to create a spray and cause rapid evaporation. Perforated pipes have been used, but these soon clog up and are ineffectual. It is best to turn off the spray at night as the outside air will be cooler. It is best in winter to bring the plants to a lighter house where they can get all the sun in the dull months, as most of the growth is made during the winter and needs to be well matured and strong to carry the plants through the flowering period of early summer months. In March, there are very bright days when a little shade is necessary, and early in April removal should be made to summer quarters in the coolhouse proper. One very hot summer has been known to undo the upbuilding of several preceding cool ones. Odontoglossums are freely raised from seeds by the hybridist in Europe, but have never been raised in the American collections. Their seeds germinate the readiest of any orchids, coming up like grass in a few weeks after sowing, but invariably go down again during the heat of "dog days" in summer. The hybrids imported seem to have more vigor, especially those that have *O. nobile* as a parent. One of the most wonderful phases of the hybridists' work is seen in the great variety produced, the proving up of the origin of many supposed species of Reichenbach and others, the reproduction of fine types from seeds true to themselves in a measure, but usually with an admixture of the poorest present, showing the very complex origin of our most beautiful garden orchids as they were found first. The partial extinction of these odontoglossums by the march of cultivation of coffee and other valuable crops in the Andes has no longer any terror to the cultivator, equally good forms now being raised in gardens, and sometimes flowered in months rather than years. There is still the element of uncertainty as to what will appear, as with the native imported pieces. Even the once rare native natural hybrids are now produced, but from the finest types as parents, and sold now at modest prices. It is too much to expect that the cultivation of *O. crispum* and other coolhouse species will become general until there is certainty of control of temperatures in summer as in winter. Good results have been gained by giving a weak solution of ammonium phosphate, two ounces potassium nitrate, three ounces to three gallons of water, using one ounce of this stock solution to each gallon used for the plants. This is known as the "Cookson formula," advocated by a cultivator who noticed that odontoglossums flourished in the vicinity of smoky cities, and it was traced to the deposit of soot on the glass roofs carried by rain-water into the cisterns to be used for the plants. Rain-water is seldom conserved here for watering orchids, but the addition of this slight quantity of fertilizer seems to be beneficial and to take the place of the rain-water.

SYNOPSIS OF SECTIONS.

A. *Fls. yellow, variously spotted with brown, crimson, etc.*

Section I. Ground-color of the labellum yellow... Species 1–14

Section II. Ground-color of the labellum white, rarely pale yellow or changing to yellow. Species 15–28

AA. *Fls. white, sometimes shaded with rose or cream, never with a bright yellow or greenish yellow ground-color.*

Section III. Plants not dwarf: fls. numerous, in branched panicles much exceeding the lvs..... Species 29–34

Section IV. Plants manifestly of dwarf habit: fls. few, in slender racemes, with the scape (and often the whole infl.) shorter than the lvs., rarely exceeding them .... Species 35–44

AAA. *Fls. dark purple.*

Section V. Fls. numerous, small, in large, branched panicles .... Species 45

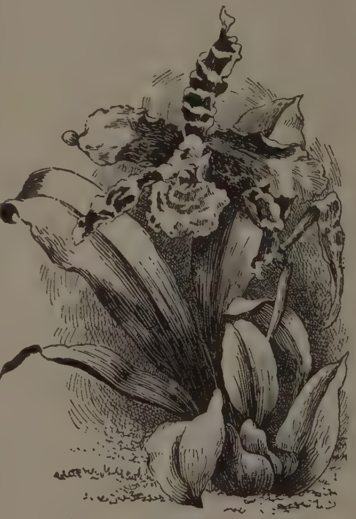
Section I.

A. *Labellum reniform, larger than the rest of the fl.* .... 1. **Londesboroughianum**
AA. *Labellum oblong or fan-shaped, shorter than the sepals; apex rounded, emarginate, or acute; margin entire.*
B. *Apex rounded or emarginate.*
C. *Sepals sub-rotund* .... 2. **brevifolium**
CC. *Sepals oblong to lanceolate.*
D. *Column with 2 blunt auricles.*
E. *Fls. marked with red-brown* .... 3. **grande**
EE. *Fls. marked with darker yellow* .... 4. **Schlieperianum**
DD. *Column with 2 cirrhous teeth* .... 5. **Insleayi**
6. **Coradinei**
BB. *Apex acute* .... 7. **Lindleyanum**
AAA. *Labellum variously shaped, fimbriately toothed, and having a pectinate crest* .... 8. **luteo-purpureum**
9. **facetum**
AAAA. *Labellum triangular or triangular-oblong, long-acuminate* ....10. **hebraicum**
11. **maculatum**
AAAAA. *Labellum lanceolate, cordate or hastate at base.*
B. *Column with rhomboid wings*...12. **mirandum**
BB. *Column with 2 subulate awns at apex* ....13. **gloriosum**
14. **odoratum**

1. **Londesboroughiànum,** Reichb. f. Pseudobulbs roundish ovate, 1–2-lvd.: raceme 3–6 ft. long, bearing as many as 30 fls.; sepals oblong, undulate, apiculate; petals obtuse, apiculate, wider; both light yellow, with many abrupt, narrow, concentric brown markings; blade of the labellum extending beyond the sepals, over 1 in. across, light yellow, with few brown blotches at base. Autumn. Mex. I.H. 30:497. Gn. 16, p. 502. F.M. 1877:246.—A distinct plant resembling an oncidium. Var. **pardinum,** Hort. Lip profusely dotted with brownish crimson. Gn. 16, p. 503.

2. **brevifòlium,** Lindl. (*O. coronàrium,* Hort.). Plants with leathery, ovate-oblong, spreading lvs. and erect racemes, about 1 ft. high, bearing 10–20 fls. 2–2½ in. diam.; sepals subrotund-unguiculate, undulate; petals similar, smaller; labellum smaller than the sepals, cuneate-emarginate, yellow in front, marked about the column with yellow and purple, with a 3-toothed tubercle on the base. Colombia. I.H. 21:170. G.C. II. 24:177; III. 18:489; 19:79. G.M. 34:819; 38:127.

3. **grânde,** Lindl. Baby Orchid. Fig. 2561 (redrawn from "The Garden"). Pseudobulbs 2-lvd.: lvs. broadly lanceolate: scape few-fld., twice as long as the lvs.; sepals lanceolate, the lateral ones keeled, yellow, banded with rich reddish brown spots; petals oblong, broader, obtuse, subundulate, apex yellow; labellum almost rotund, apex slightly emarginate, yellow, banded and spotted with rusty blotches, and with a large-lobed tubercle on the claw. Autumn. Guatemala. B.M. 3955. F.S. 1:24, 25. P.M. 8:49. Gn. 48, p. 219; 51:118. G.C. III. 17:41 (abnormal fls.); 42:387.—A magnificent species with half-drooping racemes a foot long, bearing few large, brilliantly colored fls. 5–6 in. diam.



2561. Odontoglossum grande.

4. **Schlieperiànum,** Reichb. f. (*O. Ínsleayi* var. *macrànthum,* Lindl.). Fls. on erect racemes, pale yellow, blotched and barred with deeper yellow mostly on the

lower half of the segms. Autumn. Costa Rica. G.C. 1865:1082; II. 25:269. F.S. 17, p. 78.—Resembles a small pale *O. grande*, but fine for summer flowering.

5. **Ínsleayi,** Lindl. (*Oncídium Ínsleayi*, Barker). Lvs. leathery, oblong, shorter than the raceme: fls. 3½–4 in. across, yellow, spotted with brown, borne in a stiff, erect raceme; sepals and petals oblong, undulate, nearly equal; labellum shorter, ovate, retuse, sagittate and tuberculate at base, orange-yellow, spotted with reddish brown. Oct.–Dec. Mex. F.S. 1:49. Gt. 39, p. 474.—Free-flowering. Resembles *O. grande*. Var. **spléndens,** Reichb. f. Fls. larger, labellum and segms. clouded with brown, yellow only at the tip. Gn. 25:148. G.C. II. 25:305. Var. **leopardìnum,** Hort. A highly colored form: segms. pale yellow, heavily barred with chestnut-brown. R.B. 14:61.

6. **Coradínei,** Reichb. f. (*O. Lindleyànum*, Reichb. f. & Warscz. × *O. críspum*, Lindl.). A supposed natural hybrid with the habit of *O. crispum*. Raceme arching, few-fld.; fls. stellate, 3 in. across, dark sulfur-color, with few chestnut-brown spots; sepals and petals oblong, acuminate, undulate; labellum shorter, oblong-acute, whitish, with a large oblong red-brown blotch near the center and several smaller ones on the disk; crest 3-toothed on each side. Winter. Colombia. G.C. 1872:1068; II. 24:200; 25:269; III. 25:315.—Resembles *O. triumphans*, but of more slender growth. Var. **supérbum,** Hort. A more robust variety with richly colored fls.: panicle much branched, 2 ft. long. Mex. Var. **grandiflòrum,** Reichb. f. Fls. yellow, blotched and spotted with dark brown, large and handsome. Colombia.

7. **Lindleyànum,** Reichb. f. & Warscz. Lvs. linear: raceme lax; fls. 2–3 in. across, thin; sepals and petals yellow, blotched and striped with brown; lateral lobes of the labellum small, white, with purple spots; middle lobe red-brown, tipped with yellow. Spring. Colombia. —A variable species, supposed to be the parent of many hybrids.

8. **lùteo-purpùreum,** Lindl. Lvs. ensiform, narrowed at base: fls. showy, 2–3 in. across, in a robust horizontal raceme; sepals ovate-oblong, undulate, brownish purple, with a yellow margin; petals similar, toothed and spotted with purple-brown; labellum quadrifid, cordate or oblong, fimbriate, yellow, spotted with purple and rose; crest on the claw pectinate. Winter and spring. Colombia. G.C. II. 21:585. G.W. 2, p. 611. —Owing to its wide geographical scope, this species is extremely variable. A very mixed progeny has resulted from the crossing of this with other species, and the intermixture of the descendants. Var. **radiàtum,** Hort. (*O. radiàtum*, Reichb. f.). Sepals and petals narrow, yellow, heavily spotted with dark brown; labellum expanded in front, white, shading into a brownish blotch at base. G.C. II. 25:76, 140. Var. **crispàtum,** Reichb. f. Front half of the labellum convolute into deep folds, fimbriate. G.C. III. 5:233. Not advertised. Var. **scéptrum,** Reichb. f. Sepals creamy yellow, barred and washed with brown; petals broader-toothed, densely spotted with brown; labellum whitish. I.H. 18:73; 37:99. Not advertised. Var. **hýstrix,** Hort. (*O. hýstrix*, Hort.). Labellum much fringed, and crests very spiny.

9. **facètum,** Reichb. f. (*O. Hállii*, Lindl. × *O. lùteo-purpùreum*, Lindl.). Natural hybrid: sepals lanceolate, straight, light yellow, with very large cinnamon-colored blotches; petals lanceolate, straight, finely toothed, with numerous small spots; labellum almost circular, short, finely fringed, convolute, undulate, light yellow, with a semicircle of radiating keels, some of which are fringed and in front of which is a horseshoe-shaped spot.

10. **hebràicum,** Reichb. f. (*O. cristàtum*, Lindl. × *O. cirrhòsum*, Lindl.). Natural hybrid: fls. 2½ in. across, borne in a panicle; sepals lanceolate; petals wider, undulate, all prettily marked, lemon-yellow, whitish in the center and spotted with red-brown markings suggesting Hebrew characters; labellum triangular or oblong, acuminate, erose-dentate, darker yellow toward the base, with a large maroon blotch and several smaller ones. Winter. Colombia. Gn. 21:. 386. G.C. II. 16: 173. Var. **aspérsum,** Rolfe. Differs slightly from the type in its lax racemes of golden yellow fls., blotched with purple-brown.

11. **maculàtum,** La Llave & Lex. Pseudobulbs ovate, 1-lvd.: lvs. lanceolate, acute, 6–8 in. long: raceme pendulous, loosely many-fld., longer than the lvs.; sepals narrowly linear or lance-oblong, acuminate, brown; petals ovate-lanceolate, acuminate, undulate, yellow, spotted with brown; labellum wide triangular, acuminate, crisp, yellow, brown-spotted, claw short, 2-crested; column white. Mex. B.M. 6455 (not 4878, which is *O. cordatum*, Lindl.). B.R. 26:30.—Fls. freely in June. Racemes a foot long, with stellate fls. 3 in. diam. Var. **Thompsoniànum,** Hort. Infl. vigorous, the fls. 3–3½ in. across; sepals salmon-brown, yellow-margined; petals and lip pale yellow, brown-blotched. G.C. III. 30:77. G.M. 44:547. Var. **spléndens** and var. **supérbum** are recommended.

12. **mirándum,** Reichb. f. Lvs. lanceolate: raceme stiff, 1-sided; sepals and petals lanceolate-acuminate, almost wholly red-brown, with yellow margins; labellum linear-lanceolate, similarly marked, and having a few purple lines at base, callus horned; wings of the column rhomboid-serrate. Colombia.

13. **gloriòsum,** Lind. & Reichb. f. Fls. pallid ochre, spotted with brown, paniculate; sepals and petals oblong-ligulate, acuminate; labellum lanceolate-acuminate, cordate at base, denticulate, about as long as the petals; claw with a 4-lobed, 4-toothed callus; column toothed below the middle. Colombia. G.C. 1865:578; II. 24:680.

14. **odoràtum,** Lindl. Pseudobulbs 2–3 in. long, narrowly ovoid, compressed: lvs. 1 ft. long, narrowly ensiform: panicle sometimes 2–3 ft. long, copiously branched and many-fld.; fls. 1½–2 in. across, dull golden yellow, blotched with brownish red; sepals and petals similar, narrowly lanceolate, acuminate, waved; labellum hastate, lateral lobes short, rounded; terminal lobe broadly subulate, narrowed, pubescent, waved; disk with 2 pairs of longitudinal, obtuse, erect teeth. Winter and spring. Mex. B.M. 6502. G.C. II. 15:337. Var. **latemaculàtum,** André. Fls. larger; spots purple-brown, larger and more intense. July, Aug. I.H. 17:39. Gt. 37, p. 492. Free-flowering.

SECTION II.

A. *Labellum more or less constricted in the middle, fiddle-shaped.*
  B. *Column not winged, but having 2 projecting horns at the apex*...... 15. **constrictum**
  BB. *Column winged; wings pectinate or consisting of few decurved spines*. 16. **Hallii**
  BBB. *Column winged; wings toothed or entire.*
    C. *Crest obsolete, 5-ridged*......... 17. **læve**
    CC. *Crest falcate-pectinate*.......... 18. **Wallisii**
    CCC. *Crest of radiating keels toothed or entire*....................... 19. **tripudians**
      20. **Harryanum**
    CCCC. *Crest a bifid callosity*........... 21. **nevadense**
      22. **Sanderianum**
AA. *Labellum with an ovate or oblong blade, often cordate at the base.*
  B. *Lateral lobes not upright; labellum with a toothed crest*............. 23. **triumphans**
      24. **aspersum**
      25. **cristatum**
  BB. *Lateral lobes on the claw fleshy, upright; labellum with obtuse crest or none*.................. 26. **cordatum**
      27. **bictoniense**
AAA. *Labellum hastate*.................... 28. **hastilabium**

15. **constríctum,** Lindl. Lvs. linear-lanceolate, elongate: panicle long, slender, loosely branched; fls. 1–1¼ in.; sepals and petals nearly similar, oblong-lanceolate, acuminate, bright yellow, blotched with orange-brown; labellum fiddle-shaped, with rounded or truncate, apiculate blade, white, with a rose-colored blotch on each side, toothed. Venezuela. B.M. 5736.—Small-fld., but a profuse bloomer, often bearing 4–5 many-fld. panicles 1–1½ ft. in length. Var. **castàneum,** Hort. Spots on sepals and petals covering nearly the entire surface. I.H. 35:66.

16. **Hállii,** Lindl. Lvs. a foot long, ensiform, narrowed at the base: scape 1–2 ft. long, with a many-fld. raceme of equal length; fls. 3 in. across; sepals and petals spreading, subsimilar, oblong-lanceolate, long-acuminate with recurved points, golden yellow, with transverse bands and spots of yellowish brown; labellum white, with a blood-red spot on the middle lobe and few spots on the lateral ones, erose-dentate, midlobe emarginate, with a short awn in the sinus, with 2 spinous crests on the claw. July. Ecuador. B.M. 6237. I.H. 18:58. F.S. 17, p. 81. G.C. 1865:962; II. 25:140.—The spots on the labellum are sometimes scattered.

2562. Odontoglossum crispum. (×⅓). No. 34.

17. **læ̀ve,** Lindl. (*O. Rèichenheimii*, Lind. & Reichb. f.). Lvs. 6–10 in. long, oblong-lanceolate: sepals and petals oblong-linear, acute, plane, yellow, blotched with cinnamon; labellum smaller, white in front, violet on the upper half. Spring. Guatemala. B.M. 6265. I.H. 6:213. B.R. 30:39.—Plants bear 4–6 strict, stout panicles, 3 ft. long, with numerous fls. 2 in. diam. Not much esteemed.

18. **Wállisii,** Lind. & Reichb. f. (*O. béllulum*, Hort.). Lvs. linear-lanceolate: sepals and petals ligulate, honey-colored, marked with brown streaks; labellum white, with a violaceous anterior part and marked with similar streaks at the base, with 3-falcate calli on the base. Dec. Colombia. I.H. 18:56; 38:127.—Elegant, with slender, drooping, mostly unbranched racemes, bearing few large fls.

19. **tripùdians,** Reichb. f. & Warscz. Lvs. 7–9 in. long, linear-lanceolate: raceme stiff, erect, longer than the lvs., 8–10-fld.; fls. 2 in. across, dull yellow-green on the back; sepals oblong-acute or subacuminate, dark brown, with yellowish green tips and bases; petals similar, with yellowish bands; labellum short, panduriform, as long as the segms., white, with rose-colored blotches, with about 10 keels radiating from the disk; lateral lobes rounded, crenulate; central lobe subreniform, erose-dentate. Peru. B.M. 6029. F.M. 1876:208; 1880:407. O. 1909, p. 28.

Var. **Harryànum,** Reichb. f. Sepals and petals almost blackish inside, tipped with light yellow, with a few similar marks at the base of the petal; labellum light yellow, with the base covered with rich mauve purple.

20. **Harryànum,** Reichb. f. Lvs. about 2, oblong-ligulate, obtuse, 6–12 in. long: raceme up to 3 ft. long, bearing 6–12 large fls.; sepals and petals ligulate-oblong, acute, wavy, brown with irregular, transverse, greenish yellow markings; the petals project forward; labellum large, flat, undulate, somewhat panduriform, lower half white, changing to yellow; upper half brownish marked with mauve lines and having about 7 serrated crests; column with 2 very small toothed wings. Colombia. Gn. 33:76. G.C. III. 2:169. Same as var. of No. 19(?).

21. **nevadénse,** Reichb. f. Pseudobulbs ovate, acuminate: lvs. linear-lanceolate, base narrow, keeled: sepals and petals similar, lanceolate, long-acuminate, dark brown with a golden margin, outside dark green; limb of the labellum wide, hastate, deflexed, fimbriate, white-spotted; apex acute, subincurved, appendage on the claw bifid. Spring. Colombia. I.H. 17:45. Gn. 19, p. 425; 32, p. 589; 39, p. 250. G.C. II. 16:461; 24:201. G. 16:415.—A showy plant, with slender, arching, 6–10-fld. panicles, and fls. 3–4½ in. across.

22. **Sanderiànum,** Reichb. f. Resembling *O. nevadense.* Fls. stellate; sepals and petals lanceolate, acuminate, yellow, with numerous chocolate-brown markings; labellum cuneate, panduriform, apiculate, toothed, white or pale yellow, with a purple blotch in front; lateral lobes erect. Early spring. Trop. Amer.—Free-flowering.

23. **triúmphans,** Reichb. f. Pseudobulbs 3–4 in. long: lvs. oblong-lanceolate, 1–1¼ ft. long: scape arching, branched and many-fld., 2–3 ft. long: fls. 3–4 in. across; sepals and petals lance-oblong, subacuminate, undulate, yellow, blotched with deep crimson-brown; labellum ovate, cordate, acute, toothed and undulate, white with a roseate tip; crest of yellow or white teeth. March, April. Colombia. I.H. 16:609. G.C. 1867:516; II. 24:205; 25:141; III. 27:213 (var.) R.B. 18:121. G.M. 34:89. F. 1877:217. G. 28:185.

24. **aspérsum,** Reichb. f. (*O. maculàtum*, La Llave & Lex. × *O. Róssii*, Lindl.). Natural hybrid: lvs. oblong, acute: raceme few-fld.; sepals ligulate, acute, keeled, pale yellow, mottled with numerous brown blotches; petals oblong, acute, much broader, similar in color; labellum with a cordate, acute blade wholly whitish, callus toothed, yellow, with brown lines, pubescent. Feb., March.—Free-flowering.

25. **cristàtum,** Lindl. (*Oncídium cristàtum*, Beer). Lvs. linear-lanceolate, a little shorter than the many-fld. scape: sepals and petals lanceolate-acuminate, yellow, spotted with brown; labellum oblong-lanceolate, white; apex and margin brown, with purple striæ, with a digitate crest on the disk; wings of the column semi-ovate or subquadrate. Peru. I.H. 17:21. Var. **Dayànum,** Reichb. This is colored like the type, but the lip is rhomboid, apiculate, serrate, and the teeth of the crests on the labellum cross each other like the bristles on the nearly closed leaf of *Dionæa muscipula.*

26. **cordàtum,** Lindl. Pseudobulbs oblong, 1-lvd.: lvs. oblong, acute, 6–8 in. long: fls. large and handsome, with the sepals and petals yellowish green, richly blotched with brown; labellum cordate, acuminate, subcrenate, white, with a purplish crest at base and spotted with brown on the limb; sepals lance-linear, acuminate; petals broader and longer, undulate. Mex. B.M. 4878 (as *O. maculatum*). I.H. 26:355. P.M. 13: 147. Gn. 27:46. F.C. 3:100.—St. 2–3 ft. high: few or many-fld.

27. **bictoniénse,** Lindl. Pseudobulbs oblong, 2–3 in. long, 2–3-lvd.: lvs. 1 ft. long, ensiform, undulate, spreading: raceme 3 ft. long; fls. 1½ in. across; sepals and petals subequal, linear-lanceolate, greenish yellow, blotched with brown; claw of the labellum bilamellate, blade cordate, acuminate, undulate, white or roseate. Autumn. Guatemala. B.M. 3812 (as *Zygopetalum africanum*).—This was the first odontoglossum to reach England in a living state. It is free-flowering, but not so good as plants subsequently intro. Var. **álbum,** Hort. Like the type, but labellum pure white instead of wine-red; sepals and petals brown. I.H. 19:91.

Var. **spléndens,** Ch. Lem. Labellum rose-lilac; other segms. spotted. Seems to be like the type, with more pronounced color. I.H. 12:449.

28. **hastilàbium,** Lindl. Lvs. linear-oblong: scape 1½–2 ft.; bracts long, deciduous; fls. numerous, large, handsome, varied with pale green, purple and white, fragrant; sepals and petals spreading, lanceolate, very acuminate, pale green, with transverse purple dots and lines; labellum large, the lateral lobes forming 2 horns at base, the central one with a purple, crested claw, and orbicular-ovate, white, acute blade; column slender, winged, purple. Summer. Colombia. B.M. 4272. G.W. 13, p. 620.

SECTION III.

A. *Column without wings*............29. **ramosissi-** **[mum**
AA. *Column with 2 spreading awns*......30. **nævium**
31. **cirrhosum**
AAA. *Column pluricirrhose; segms. lanceolate*..........................32. **Ruckerianum**
AAAA. *Column with fimbriate or toothed wings; segms. ovate or rhomboid*...33. **nobile**
34. **crispum**

29. **ramosíssimum,** Lindl. Lvs. linear-oblong, acute, 1 ft. long: panicle much branched and many-fld., 2 ft. long; fls. 2 in. across, white, spotted with pale purple or violet; sepals and petals very undulate, narrowly ligulate, the latter wider; labellum rhomboid, acuminate, cordate at base, crested, tomentose. March, April. Colombia. J.H. III. 29:77. I.H. 40:170 (var. *cœleste*, Lind. & Rod.).—A distinct and beautiful plant whose fls. have been likened to large spiders.

30. **næ̀vium,** Lindl. & Paxt. Pseudobulbs oblong: lvs. thin, lanceolate: panicle erect, arching, much branched, bearing numerous star-shaped fls.; sepals and petals 2 in. long, narrowly lanceolate, beautifully crenate-undulate, white, profusely spotted with rose-purple; labellum shaped nearly like the petals, shorter and broader, with 2 large crests on the yellow base. May, June. Colombia. F.S. 6:594. G.M. 31:559. B.M. 8097.—Closely allied to *O. cirrhosum.*

31. **cirrhòsum,** Lindl. Pseudobulbs lanceolate, compressed, 2–3 in. long: lvs. 4–6 in. long, linear-ensiform, leathery: panicle often over 2 ft. long, drooping, or inclined; fls. 3 in. across, snow-white, blotched with crimson or brown, base of the labellum yellow, with brown lines at the sides; sepals narrowly lanceolate, ending in long, curved points; petals wider; labellum two-thirds the length of the petals, with 2 ciliate lateral lobes and a narrow acuminate middle lobe. April, May. Ecuador, Peru. B.M. 6317. I.H. 25:301. Gt. 41:1383. Gn. 9, p. 401; 16, p. 19. G.C. II. 5:501, 503; 9:181; 25:12. F.M.1876:222.—This species sometimes produces stout few-fld. sts., which should be cut to save the vigor of the plant.

32. **Ruckeriànum,** Reichb. f. Related to *O. crispum:* sepals and petals lanceolate, acute, creamy white, bordered with violet and spotted with brown, waved; labellum rather narrow, oblong, angular-lobed on each side of the base, yellow at base, with few chestnut-brown blotches; callus rhomboid serrate. Colombia. G.C. 1873:105; II. 24:204, 748 (var. *insigne*). J.H. III. 30:455 (var. *splendens*).

33. **nóbile,** Reichb. f. (*O. Pescatòrei*, Lind.). Pseudobulbs ovate, bearing 2 strap-shaped lvs.: panicle 2–3 ft. long, diffuse, bearing numerous white, membranaceous fls. slightly tinged with rose; sepals ovate-oblong, slightly undulate; petals similar but much wider; labellum cordate-oblong, pandurate, with a yellow fimbriate crest and a few rose-colored spots. Spring. Colombia. F.S. 16:1624. I.H. 28:407. Gn. 21:216 (as *O. excellens*). G.C. II. 24:212; III. 3:245; 7:200; 25:69.; 35: 131. A.F. 5:183. J.F. 4:331. J.H. III. 60:389. G. 31: 285; 36:307.—A fine species producing numerous large, erect panicles. Var. **Veitchiànum,** Reichb. f. Like the type, but the parts of the fl. have large, crimson-purple spots. Gn. 26:112.

34. **críspum,** Lindl. (*O. Blúntii*, Reichb. f. *O. Alexándræ*, Batem.). Figs. 2562 and 2563. Pseudobulbs ovate, compressed, about 3 in. long: lvs. linear, 1 ft. long: panicles rather short, but attaining a length of 2½ ft., with few short branches and crowded fls.; fls. white, variously spotted with crimson, brown, etc., or tinged with rose, 2–3 in. across; sepals ovate to ovate-lanceolate, often undulate; petals ovate to rhomboid, toothed and undulate-crisp; labellum oblong-ovate, fringed with teeth, wavy and crisp. Fls. are produced at any season of the year. Colombia. F.S. 16: 1652. Gn. 4, p. 241; 20:12; 21, p. 95; 23, p. 210; 40, p. 596; 46, p. 149; 53, p. 297. R.B. 21:3. Gng. 6:24; 16:133. J.H. III. 34:499; 49:329; 62:449. G.C. III. 21:379; 23:165, 390; 25:67, 179, 187; 43:4. A.F. 13: 34. F.E. 9:327. G. 4:619; 9:223; 24:662; 26:198. 35: 333. G.M. 50:527. G.Z. 21, p. 145. O. 1910, p. 24. C.L.A. 10:413; 20, Aug., p. 44.—As was stated in the introduction, this species has probably more than 100 named varieties. Many besides those cited have been figured in horticultural and botanical works. Very few varieties are found in American trade lists, but some of the most distinct are given below:

2563. Habit sketch of Odontoglossum crispum.

Var. **Andersoniànum,** Hort. (*O. Andersoniànum*, Reichb. f.). Fls. creamy white, with broad, longitudinal bands of cinnamon. F.M. 1872:45. G.C. II. 24:680, 681; III. 17:739. G.W. 13, p. 619.—Listed in Amer.

Var. **apiàtum,** Ballantyne. Fls. very large; sepals and petals laciniate on the edges, white, with rich chocolate-brown blotches. G.C. III. 15:375.

Var. **Ashworthiànum,** O'Brien. Fls. almost entirely rose-purple, with white margins and a few white marks on the sepals and petals. G.C. III. 19:197.

Var. **Coòksoniæ,** Hort. Fls. 4 in. across, the segms. fringed and heavily tinged with purple on back, the face pure white around the column, the margins white, tinged purple in places, the segms. with a large central purple-red blotch, surrounded with smaller blotches. G.C. III. 33:109.

Var. **Fowleriànum,** Hort. Fls. white, the sepals with 2 large irregular ruby-crimson blotches and smaller purple ones, the petals with large ruby-crimson blotches separated by narrow white lines; lip crimped, purple-marked, the crest yellow. G.C. III. 41:278; 45:211.

Var. **Gouvilleànum,** André. Fls. large, white; petals irregularly toothed, with few small crimson blotches; sepals heavily blotched. R.H. 1888:132.

Var. **Grairiànum,** Hort. Sepals and petals for most part a glowing yellowish rose, the margins white with a few white inward-running lines; crest yellow. G.C. III. 33:407.

Var **guttàtum,** Hort. (*O. Alexándræ* var. *guttàtum,* Hook.). Sepals linear-oblong, with several pale purple blotches; petals broader, similarly spotted; labellum oblong-quadrate, contracted in the middle, spotted with rose and having a large rose patch on the disk. B.M. 5697.

Var. **Kárthausii,** Hort. Sepals and petals strongly toothed, pure white or tinted in places on the margins, with several large irregular, more or less confluent bright purple central blotches; lip marked with red-brown. C.O. 1 *s.*

Var. **Léhmanni,** Hort. Labellum broadly ovate, bright ruby-red, broadly edged with white; crest yellow; sepals and petals tinged with rose, with few red spots. G.C. III. 24:147.—In American trade.

Var. **Lùciani,** Hort. Sepals and petals violet on back, marked on face with large irregular purple-brown blotches. C.O. 1*s.*

Var. **maculàtum,** Hort. Fls. white, spotted with purplish brown; petals suborbicular, laciniate-toothed. G.C. III. 16:248.

Var. **Marìæ,** André. Fls. pure white, except a few red spots on the base of the sepals. I.H. 25:325.

2564. Odontoglossum Cervantesii var. decorum. (×⅓)

Var. **Mundyànum,** Hort. Fls. white, rose-purple tinged, heavily blotched with chestnut or red-brown, the center of lip bright yellow. G.C. III. 27:117.

Var. **Pittiànum,** Hort. Fls. white, slightly rose-tinged, the acuminate sepals and petals heavily blotched with red-brown, the back heavily tinged with purple; lip with a yellow crest marked with reddish lines and brown-spotted. G.C. III. 30:154. G.M. 49:212.

Var. **purpuràscens,** Hort. Fls. heavily tinged with rose-purple, the dorsal sepal and petals with numerous small well-defined reddish purple spots, the spots on the lateral sepals obscured by the coloring; lip white with reddish blotches in front, the crest yellow, with a few reddish lines. G.C. III. 29:233. G.M. 46:391. J.H. III. 42:275.

Var. **Sánderæ,** Hort. Fls. purple-tinted, heavily blotched with reddish orange-brown. G.C. III. 33:416. J.H. III. 43:3.

Var. **Schroèderi,** Hort. Fls. with 1 or 2 large and several small, brownish red spots on the white segms. Advertised in Amer.

Var. **Triànæ,** Hort. (*O. Alexándræ* var. *Triànæ,* Hook.). Dorsal sepals with a single roseate spot; lateral sepals suffused and spotted with rose; petals pure white; labellum with a large 2-lobed spot. B.M. 5691.

Var. **Veitchiànum,** Hort. Sepals ovate, undulate, white, with several brownish crimson spots; petals broader, color like the sepals but mostly in one large central blotch; margins undulate and toothed. G.C. III. 1:799. F. 1884:177. G.Z. 30:217.

SECTION IV.

A. *Sepals and petals similarly colored.*
  B. *Column without wings.*
    C. *Pseudobulbs compressed and edged.*
      D. *Labellum white or colored like the petals*..................35. **madrense**
        36. **nebulosum**
      DD. *Labellum violet*..............37. **Krameri**
    CC. *Pseudobulbs smooth, terete*......38. **Oerstedii**
  BB. *Column with entire wings*.........39. **Cervantesii**
  BBB. *Column with toothed or crenate wings.*
    C. *Labellum reniform*............40. **citrosmum**
    CC. *Labellum oblong-quadrate*.......41. **pulchellum**
        42. **Egertonii**
AA. *Sepals and petals dissimilar in color*..43. **Rossii**
        44. **Dawsonianum**

35. **madrénse,** Reichb. f. (*O. maxillàre,* Hook.). Pseudobulbs long-ovoid: lvs. strap-shaped, 10 in. long: fls. 2½ in. across, 4–10 in a raceme; sepals and petals lanceolate, keeled, white, with a purple blotch at the base; labellum shorter than the sepals, the lateral lobes forming 2 acute recurved appendages on the claw, middle lobe trowel-shaped, white, with a yellow base and an orange blotch. Summer. Mex. B.M. 6144. I.H. 30:480. F.M. 1875:158. Gn. 10, p. 443. G.C. II. 25:116 (seed-pod). G.M. 39:117. G. 2:535.

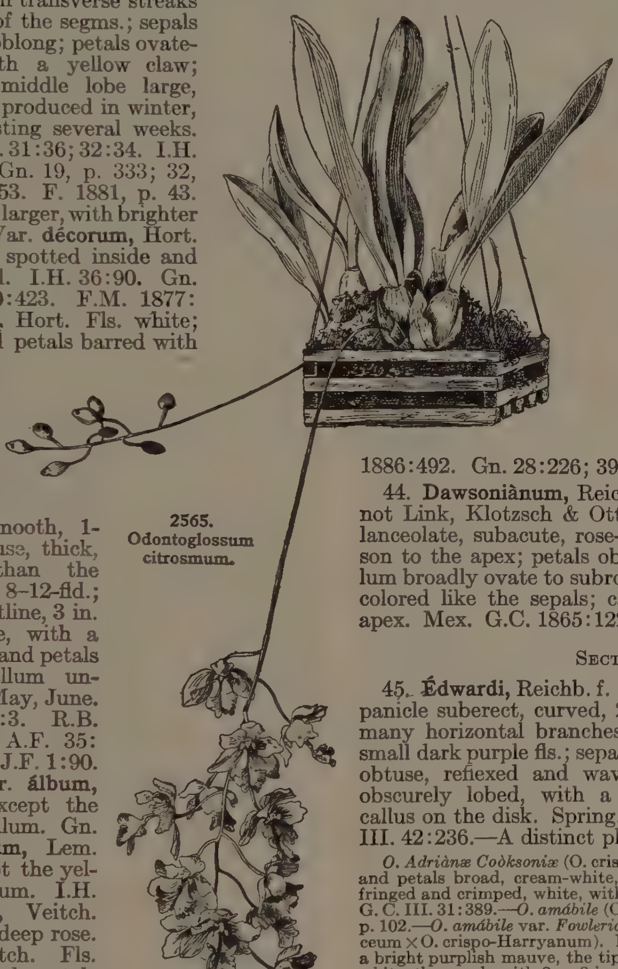
36. **nebulòsum,** Lindl. (*O. maxillàre,* Lindl.). Pseudobulbs 2–3-lvd.: lvs. oblong, acute, 9 in. long: scape about as long as the lvs., 5–6-fld.; fls. 3 in. across, pure white, with the bases of all the parts profusely spotted with brown; sepals membranaceous, oblong; petals similar but wider, all pubescent at the base; labellum with 2 large, erect lobes on the yellow claw; limb ovate, acute, dentate, pubescent. Mex., at an elevation of 10,000 ft. I.H. 6:200. G.C. 1867:572; II. 25:597. Not B.M. 6144, which is *O. madrense.* Var. **candídulum,** Reichb. f. Sepals and petals pure white, with a brown blotch and a few spots on the labellum. G.C. 1867: 710; II. 25:596. Var. **guttàtum,** Reichb. f. Sepals and petals spotted to above the middle. I.H. 31:524.

37. **Kràmeri,** Reichb. f. Pseudobulbs subrotund, compressed and sharply 2-edged, 1-lvd.: lvs. 7–9 in. long, 1½–2 in. broad, keeled: scape 4–8 in. long, inclined or pendulous, 3–5-fld.; fls. 1½ in. diam.; sepals and petals subequal, oblong-acute, pale violet-red in the center, with broad white margins; labellum with a stout yellow excavated claw bearing 2 erect calli; middle lobe subquadrate, 2-lobed, pale violet, with white and brown streaks at base. Costa Rica and Mex. B.M. 5778. I.H. 32:562. F.S. 23:2469. G.C. 1868:98; II. 25:756.

38. **Oérstedii,** Reichb. f. Plants small: lvs. linear-oblong, 4–5 in. long, narrowed to a petiole: raceme suberect, few-fld.; fls. 1½ in. across, white, with the base of the labellum golden yellow; sepals and petals broadly

oblong, the latter narrowed to a short claw; labellum sessile; lateral lobes small, auriculate; middle lobe suborbicular, plane, deeply bifid. Feb.–May. Costa Rica. B.M. 6820. Gn. 26:160. G.C. II. 7:811; 25:757; III. 19:77. G. 28:261.

39. **Cervántesii,** La Llave & Lex. (*O. membranàceum,* Lindl.). Pseudobulbs usually 4-angled, 2 in. long, bearing a single oblong lf. 4–6 in. long: scape sheathed with large bracts, bearing 2–6 membranaceous fls.; fls. 2 in. across, pure white, with transverse streaks of red near the bases of the segms.; sepals broadly lanceolate to oblong; petals ovate-rotund; labellum with a yellow claw; lateral lobes small; middle lobe large, broadly cordate. Fls. produced in winter, very fragrant and lasting several weeks. Mex. B.M. 4923. B.R. 31:36; 32:34. I.H. 1:12. P.M. 12:193. Gn. 19, p. 333; 32, p. 323. G.C. II. 15:753. F. 1881, p. 43. Var. **màjus,** Hort. Fls. larger, with brighter spots. I.H. 25:313. Var. **décorum,** Hort. Fig. 2564. Fls. large, spotted inside and outside with bright red. I.H. 36:90. Gn. 32:322. J.H. III. 30:423. F.M. 1877: 254. Var. **Ándersonii,** Hort. Fls. white; base of the sepals and petals barred with reddish brown; labellum bordered with spots of the same color. Mex.



2565. Odontoglossum citrosmum.

40. **citrósmum,** Lindl. Fig. 2565. Pseudobulbs subrotund, compressed, smooth, 1-lvd.: lvs. oblong, obtuse, thick, somewhat shorter than the raceme: scape pendent, 8–12-fld.; fls. large and full in outline, 3 in. across, white to rose, with a violet labellum; sepals and petals oblong, obtuse; labellum unguiculate, reniform. May, June. Guatemala. B.R. 29:3. R.B. 21:265. F.S. 6:633. A.F. 35: 480. Gn. W. 18:545. J.F. 1:90. J.H. III. 51:27. Var. **álbum,** Veitch. Fls. white, except the yellow claw of the labellum. Gn. 24:414. Var. **roséllum,** Lem. Fls. rose-colored, except the yellow claw of the labellum. I.H. 2:59. Var. **ròseum,** Veitch. Blade of the labellum deep rose. Var. **punctàtum,** Veitch. Fls. pale rose; sepals and petals spotted with purple. A variety called **máximum** is also advertised.

41. **pulchéllum,** Batem. Pseudobulbs oblong, compressed, 2-lvd.: lvs. grass-like, rather stiff or rigid, 9–12 in. long: scape weak, 6–7-fld.; fls. white, except the yellow crest of the labellum; sepals ovate, acute; petals obovate, acute, somewhat undulate; lateral lobes of the labellum triangular, middle lobe oblong, subquadrate, apex recurved; column very short, with 3 fimbriate wings. Spring. Guatemala. B.M. 4104. B.R. 27:48. O. 1912, p. 150. G. 33:153.—Easily grown, and never fails to blossom. The fl.-spikes suggest the lily-of-the-valley. Fragrant. Var. **màjus,** Hort. More robust than the type, with larger fls. Var. **grandiflòrum** is listed.

42. **Égertonii,** Lindl. Like *O. pulchellum,* but with the fls. only half as large: labellum acute, not almost truncate, excavated at the base and with 2 teeth inflexed over the excavation. Guatemala.—This is probably only a form of *O. pulchellum.*

43. **Róssii,** Lindl. Pseudobulbs small, much compressed, 1-lvd.: lvs. about 6 in. long: raceme about as long as the lvs., 2–5-fld.; fls. 2–3 in. diam.; sepals lanceolate, acuminate, cream-colored to greenish yellow, with short bars of dark brown; petals white, with a few brown spots at base, oblong, obtuse, revolute; labellum round-ovate, emarginate, undulate, pure white, except the yellow claw. Winter. Mex. F.C. 3:129. B.R. 25:48. Gn. 19, p. 306; 28: 226. F.S. 20:2110.—This is an extremely variable species, and probably includes the forms cult. as *O. Ehrenbergii* and *O. Dawsonianum,* which are united with this species by some authors. The name *majus* has been applied to several varieties. Probably I.H. 1: 30 (as *O. Ehrenbergii*) and F.S. 8:846 (as *O. Ehrenbergii* =*O. apterum,* ex-Index Kewensis) also belong here. Var. **rubéscens,** Carr. (*O. Róssii màjus rubéscens* Hort.). Fls. large; petals clear rose, with dark brown spots at the base. R.H. 1886:492. Gn. 28:226; 39, p. 345. G.C. II. 21:345.

44. **Dawsoniànum,** Reichb. f. (*O. Éhrenbergii,* Hort., not Link, Klotzsch & Otto). Raceme few-fld.; sepals lanceolate, subacute, rose-colored, blotched with crimson to the apex; petals oblong, acute, pure rose; labellum broadly ovate to subrotund, crenulate; apex retuse, colored like the sepals; callosity with 2 teeth at the apex. Mex. G.C. 1865:1226; II. 25:469. F.S. 17, p. 76.

SECTION V.

45. **Édwardi,** Reichb. f. Lvs. 2 ft. long, strap-shaped: panicle suberect, curved, 2 ft. long, the rachis bearing many horizontal branches covered with many rather small dark purple fls.; sepals and petals oblong to ovate-obtuse, reflexed and wavy; labellum tongue-shaped, obscurely lobed, with a prominent yellow lobulate callus on the disk. Spring. Ecuador. B.M. 6771. J.H. III. 42:236.—A distinct plant, easily cult.

O. Adriànæ Coòksoniæ (O. crispum × O. Hunnewellianum). Sepals and petals broad, cream-white, evenly brown-blotched; lip finely fringed and crimped, white, with fine brown spots and yellow crest. G.C. III. 31:389.—*O. amábile* (O. crispum × O. spectabile). O. 1913, p. 102.—*O. amábile* var. *Fowleriànum* (*O.* crispum punctatum violaceum × O. crispo-Harryanum). Fls. 4 in. across, the sepals and petals a bright purplish mauve, the tips pale violet, the margins silvery white, the sepals with 2 or 3 irregular white lines, the petals with a few white spots; lip white in front, and red around the yellow crest, marked with rose. G.C. III. 44:4.—*O. ardentíssimum* (O. crispum × O. nobile). Fls. most like those of O. crispum in size and form, white, blotched claret-purple, the crest yellow with reddish markings. G.C. III. 32:50.—*O. aspidorhìnum,* Lehm. Fls. 9–15, the sepals and petals oblong, contracted into long points, yellow, blotched with red-brown; lip subpanduriform, clawed, white, spotted with lilac-crimson. Colombia. G. 31:643.—*O. Bingeliànum* (O. crispum × O. Harryanum). G.M. 51:69.—*O. blándum,* Reichb. f. Sepals and petals pale yellowish white, spotted with crimson-brown, cuneate-lanceolate, acuminate; lip ovate, acuminate, crisped. Colombia.—*O. Brádshawiæ* (O. Andersonianum × O. Harryanum). Fls. 4½ in. across, resembling more those of O. Harryanum, yellow, tinged with rose on back of sepals, marked on the face below with numerous red-brown blotches, more or less confluent in groups. G.C. III. 33:82. G.M. 46:87. Gn. 63, p. 184.—*O. cærùleum* (O. armainvillurense × O. crispum). Fls. resembling in shape those of O. ardentissimum, the greater part of the segms. marked with confluent blotches of violet-purple. G.M. 50:413.—*O. Clàytii*=(?).—*O. Crawshayànum* (O. Hallii × O. Harryanum). Fls. intermediate in shape between the parents, but more like O. Hallii in color. G.C. III. 30:77.—*O. críspo-Harryànum* (O. crispum × O. Harryanum). More like the second parent in shape, the sepals and petals light yellow, smaller basal markings of red-brown. G.C. III. 45:133. G.M. 52:144.—*O. Edgertoniànum*=perhaps O. Egertonii.—*O. Fowleriànum* (O. cirrhosum × O. Rossii). Sepals and petals narrow, thickly spotted deep purple, bright rose-purple on margins and tips. the lip rose-purple, the callus yellow. G.M. 49:181. Gn. 69, p. 173.—*O. Gròganiæ* (O. Edwardi × O. Uroskinneri). Fls. rose-purple, with the crest yellow. G.C. III. 49:72.—*O. harvengténse* (O. crispum × O. triumphans). Sepals and petals pale yellow, spotted with red-brown, the latter with a paler central strip, the lip brown-spotted, the center yellow, the margins white. C.O. 4.—*O. Hárwoodii* (O. Wiganianum × O. maculatum auriferum). Fls. yellow, spotted dark purple. G.C. III. 49:98. G.M. 54:93.—*O. Lambeauiànum exquísitum* (O. crispum Madame Folcke × O. Rolfeæ ardentissimum). Segms. white, rose-suffused on petals, blotched red-brown. G.C. III. 38:434. C.O. 12. O.R. 14:57.—*O. Lawrenceànum* (O. Rolfeæ × O. triumphans). Fls. bright yellow, heavily brown-barred, the white lip purple-blotched. Gn. 67, p. 207.—*O. Leeànum*, Reichb. f. Fls. yellow, brown-blotched. Colombia. B.M. 8142. J.H. III. 43:193.—*O. Lucasiànum* (O. cristatellum × O. Hallii). Sepals and petals chocolate, margined and tipped yellow, lip cream-white, brown-spotted.—*O. Ossuttònii* (O. nobile × O. spectabile). Sepals and petals cream-yellow, spotted and blotched brown, the sepals flushed rose. G.W. 13, p. 212. G.M. 49:419.—*O. Phalænópsis*=Miltonia Phalænopsis.—*O. ramulòsum*, Lindl. Fls. bright yellow, with a large basal blotch of brown on dorsal sepal and petals, the lateral sepals brown-spotted, the lip with a brown band in front of the orange crest. Colombia. B.M. 8031.—*O. Roèzlii álbum*=Miltonia Roezlii alba.—*O. Rólfeæ* (O. Harryanum × O. nobile). Fls. ivory-white, with numerous small purple spots, those of the lip basal, those on the petals in a central zone, the sepals slightly purple-stained at tip. Gt. 58:1580.—*O. rosefieldiénse* (O. Harryanum × O. Lambeauianum). Fls. white, slightly tinged pink, blotched with various shades of reddish claret. G.C. III. 49:163.—*O. Smíthii* (O. Rossii × O. spectabile). Sepals and petals light green, margined with violet-purple, in upper half blotched black-brown, the front lobe of lip violet-purple, the disk and crest yellow. G.C. III. 38:427; 45:212. G.M. 48:805.—*O. Thompsoniànum* (O. crispum × O. Edwardi). Fls. rich claret-purple, the margins and tips rosy, the crest deep yellow.—*O. venùstulum* (O. armainvillurense × O. spectabile). Fls. white tinged lilac and heavily purple-blotched. G.C. III. 38:2.—*O. vexillàrium* =Miltonia vexillaria.—*O. Vuylstékeæ* (O. spectabile × O. Vuylstekei). Fls. rosy claret, with slight silvery white lines between the confluent blotches. G.C. III. 38:379. G.M. 48:743.—*O. Vuylstékei* (O. Durisonæ × O. triumphans). Sepals and petals deep red-brown, the apex and margins light yellow, a narrow irregular transverse line about the middle, the lip whitish with few irregular brown spots. G.M. 47:59.—*O. waltonénse* (O. crispum × O. Kegeljani). Fls. resemble in shape more those of O. crispum, soft canary-yellow, the lip pandurate with a bright red-brown blotch in front of crest. G.C. III. 33:51. G.M. 46:73. O.R. 11:49.—*O. Wárneri*=Oncidium Warneri.—*O. Wattiànum Crawshayànum* (O. Harryanum × O. Lindleyanum). Sepals and petals yellow, closely marked with brown, the lip white with a large violet-purple blotch and some smaller ones. G.C. III. 28:286.—*O. Wattiànum príncеps* (O. Harryanum × O. Lindleyanum). Sepals and petals pale yellow, heavily blotched with chocolate-purple, the white lip with violet basal markings. G.C. III. 41:135.—*O. Wéltonii*=Miltonia Warscewiczii.—*O. Wendlandiànum Crawshayànum* (supposedly a natural hybrid). Sepals purple, yellow-margined, with a few basal chocolate blotches, the petals tinged claret, profusely spotted with brownish purple. G.C. III. 27:275. G.M. 43:521.—*O. Wiganiànum* (O. harvengtense × O. Rolfeæ). Sepals and petals bright canary-yellow, the sepals bearing few large, the petals numerous small red-brown spots, the lip white at base, primrose in front, with a few purple spots at the middle. G.C. III. 37:274.—*O. Wilckeànum Rothschildiànum* (O. crispum × O. luteo-purpureum). Sepals yellow, blotched and barred with brown, the petals light yellow, marked with brown in center, the lip fringed, orange-yellow at base, the front lobe yellow with a large purple blotch. G.C. III. 32: suppl. Dec. 6.—*O. Wyoniànum* (hybrid). Fls. white, the middle area of segms. blotched with red-purple. G. C. III. 45:211.

Heinrich Hasselbring.
George V. Nash.†

ODONTÒNIA (compounded of *Odontoglossum* and *Miltonia*). *Orchidàceæ.* A genus established to include hybrids of the genera Odontoglossum and Miltonia.

Odontònia brugénsis=O. Edwardi × M. vexillaria.—*O. Chólletii*=O. Harryanum × M. vexillaria.—*O. Cleverlyàna*=O. Rolfeæ × M. vexillaria Leopoldii.—*O. décora* =O. Adrianæ × M. Warscewiczii.—*O. George V. Nash.

ODONTOSÒRIA (Greek, *toothed leaf*, alluding to the fact that the sori are on slender segms. of the leaf). *Polypodiàceæ.* A group of tropical ferns formerly included with Davallia; characterized by the decompound lvs. with cuneate ultimate segms. and the compressed suborbicular or cup-shaped indusium which is attached at its sides and open only at the top. For cult., see *Fern.*

chinénsis, J. Smith (*Davállia chinénsis*, Smith. *Stenolòma tenuifòlia*, Fée). Lf.-blades 12–18 in. long, 6–9 in. wide, quadripinnatifid, on polished dark brown stalks which rise from stout creeping fibrillose rootstocks; ultimate divisions with toothed cuneate lobes; sori terminal, usually solitary. Trop. Asia and Aus-Polynesia. Var. **stricta,** Hort., has a more upright habit and narrower lvs.

L. M. Underwood.
R. C. Benedict.†

ŒCEÓCLADES: *Saccolabium.*

ŒNÁNTHE (name refers to the vinous scent of the flowers). *Umbellíferæ.* About 30 species of glabrous often aquatic perennial herbs, rarely transferred to grounds; some kinds are poisonous. They are widely distributed about the world in temperate regions: roots fibrous or tuberous: lvs. 1–3-pinnate, much dissected, sometimes reduced to a hollow or fistular petiole: fls. white, small, in compound umbels, often polygamous and the outer ones usually sterile and rayed; calyx-teeth minute; petals 2-lobed or notched with an inflexed point. **Œ. fistulòsa,** Linn. Water Dropwort, native in Eu., W. Asia and N. Afr., is listed abroad: roots of many fleshy fibers, running deep: st. 2–3 ft. high, stoloniferous, very hollow and thick, little branched: radical lvs. 2-pinnate, the lobed segms. cuneate; st.-lvs. reduced mostly to hollow stalks, bearing at the apex only a few linear-lobed segms.: umbels terminal, each with 3–5 rays. Adapted to wet places, for its ornamental and interesting character.

L. H. B.

ŒNOCÁRPUS (*wine fruit*, as some of the species yield a beverage). *Palmàceæ.* A few species of S. American tall pinnatisect-lvd. palms differing from Euterpe in character of calyx and infl.; little grown, but numerous in the Amazon and Oronoco countries. The lvs. are borne in a large crown, and the fls. are in spikes arising beneath the lvs. Some of the species yield useful oil: fr. a medium-sized usually purple or black berry. *Œ. Bacàba*, Mart., and *Œ. Bataùa*, Mart., are the species most likely to be mentioned.

ŒNOTHÈRA (said to be Greek for *wine-scenting;* in allusion to an ancient use of the roots). *Onagràceæ.* Evening Primrose. Flower-garden and border plants, prized for their showy bright yellow, rose or white flowers.

Herbs, or sometimes shrubby at the base, annual, biennial and perennial, with alternate simple or pinnatisect lvs. and mostly showy fls., which are yellow, white or rose-color: calyx with a tube prolonged beyond the angled or cylindrical ovary, with 4 usually strongly reflexed lobes; petals 4, mostly obovate or spatulate; stamens 8, with narrow mostly versatile anthers: fr. a 4-valved loculicidal caps.—The œnotheras are mostly dry-soil plants and are chiefly N. American, the known species being perhaps 90–100. Some of them are S. American, and Bentham & Hooker admit 1 plant which grows in Tasmania. The genus is polymorphous, and there is consequently great difference of opinion as to generic bounds. The marked differences reside in form of caps., character of calyx-tube or hypanthium, and in the habit of the plant. What is by some botanists regarded as 1 genus is broken up into 10 or a dozen genera by others. These genera are here treated mostly as subgenera, for the group is fairly homogeneous from the horticultural point of view, and an entirely new set of names in several strange genera could scarcely be forced on the trade, particularly since the botanists are themselves not in agreement. Godetia is kept separate (Vol. III). Some of the true œnotheras make glowing displays of yellow in the border; but the greater number of the species are of only secondary importance to the cultivator. Amongst the best of the border-plant species are *Œ. fruticosa* var. *Youngii*, *Œ. linearis*, *Œ. pratensis*, *Œ. glauca* var. *Fraseri*, *Œ. cæspitosa*, *Œ. missouriensis*, *Œ. speciosa*. There are numbers of showy species in the genus, and others than those here accounted for may be expected to appear in cult. In recent years, the genus has assumed unusual interest because of the de Vriesian studies of evolution, founded on the mutations or elementary species in the Onagra group.

The œnotheras are of wide distribution in North America. They are open-ground sun-loving plants. Many of them are prominent plants of the prairies and plains. Some of them grow on the seacoasts and others in moist ground, but they are not marsh plants. The several widespread field species, the dead stalks of which, with the split upright pods (Fig. 2566), are conspicuous in pastures and on roadsides, are grouped together in current floras under the name *Œ. biennis*, but show great diversity among themselves. They are not ornamental plants, although the flowers that open first are usually rather large and attractive. The plants of the subgenus Kneiffia afford the sundrops of gardens, these cultivated plants are not well understood botanically, and it is not unlikely that some of them are hybrids or mutants.

There is nothing special to say about the culture of œnotheras except to note the tender kinds and the biennials. All do well in ordinary garden soil, enjoying sunshine. They are easily raised from seeds and cuttings. *Œ. acaulis*, *Œ. cæspitosa* are low-growing biennials which do well treated as annuals. They will not endure the winter. *Œ. missouriensis* is an excellent trailer, with enormous yellow flowers and seed vessels. It is quite hardy, and a fine rock-garden plant. *Œ. biennis*, the common evening primrose, is rather weedy, and fit only for the wilder parts of the garden. *Œ. Lamarckiana* is a better form. *Œ. fruticosa* and *Œ. Fraseri* are two of our best border kinds, with stiff branching stems. *Œ. linearis* is a pretty little species, often naturalized but well worth growing. Child's Mexican primrose is tender, but makes a pretty plant for hanging-pots. *Œ. speciosa* is a fine species, but spreads so quickly by underground stems as to become a weed in favorable situations: it is good for naturalizing in wild grounds. (T. D. Hatfield.)

CC. *Plant stemless.*
D. *Caps. with wrinkled wing-angles*.........
X. Pachylophus, No. 21.
DD. *Caps. with plane or entire wing-angles*....
XI. Lavauxia, No. 22.

I. SUBGENUS TARAXIA.

Stemless, usually perennial: stigma capitate; calyx-tube filiform: caps. sessile, narrow to ovate, usually not winged: fls. yellow.

1. **ovàta**, Nutt. Golden Eggs. Perennial: lvs. slightly pubescent, ovate to lance-oblong, 8 in. or less long, acute, serrulate or entire: fls. yellow; petals about ½in. long, orbicular; calyx-tube filiform, 3–4 in. long; fl.-bud erect: caps. to 1 in. long, more or less subterranean. Calif.

II. SUBGENUS SPHÆROSTIGMA.

St.-bearing: stigma capitate; calyx-tube short, inversely conic or funnelform: caps. sessile, linear, not winged: fls. various.

2. **bistórta**, Nutt. One to 2 ft., the base decumbent, hairy and pubescent: radical lvs. spatulate to lanceolate and petiolate, dentate; st.-lvs. mostly sessile-ovate to narrow-lanceolate and about 1 in. long, dentate: fls. yellow, turning green, the petals (about ½in. long) usually with a brown spot at the base; calyx-tube 1–3 in. long: caps. ¾in. or less long, 4-angled, contorted. S. Calif.

Var. **Veitchiàna**, Hook. More slender: radical lvs. narrow-oblanceolate and long-petioled: caps. longer and narrower (1–1½ in. long) and little contorted. S. Calif. B.M. 5078.

3. **cheiranthifòlia**, Hornem. Sts. decumbent or ascending, 2 ft. or more tall, canescent: lvs. thick, about 1–2 in. long, broad-ovate to oblanceolate or the lower ones spatulate, the upper ones becoming sessile, most of them entire: petals yellow, ¼–⅓in. long: caps. ¾in. or less long, curved or spiral, somewhat hairy. Calif. B.R. 1040.

III. SUBGENUS MERIOLIX.

St.-bearing: stigma disk-like but 4-toothed; calyx-tube shorter than the ovary, enlarging upward: caps. linear or nearly cylindrical, sessile: fls. yellow, axillary.

4. **serrulàta**, Nutt. (*Meriolix serrulàta*, Walp.). Biennial or perennial: slender, simple or branched, about 1 ft. high but variable in stature, nearly glabrous to canescent: lvs. linear to lanceolate, 1–3 in. long, usually acute, attenuate to the base, sharply dentate: petals broad-obovate, ¼in. long, wavy-margined. Minn., west and south. Mn. 7:41.

IV. SUBGENUS ONAGRA.

St.-bearing: stigma 4-cleft; calyx-tube elongated and cylindrical, enlarging at the throat: caps. linear-oblong to long-conic, 4-angled: fls. yellow, opening in evening.—True Evening Primroses, comprising a mutating group.

5. **biénnis**, Linn. (*Ónagra biénnis*, Scop.). European Evening Primrose. Fig. 2566. Usually biennial, but often flowering the first year: mature rosettes of plants grown in rich soil 2 ft. diam.: roots large and fleshy, often 2 in. diam. at the crown: st. about 3–4 ft. tall, copiously branched, green: lvs. varying from narrowly oblanceolate below to ovate above: calyx-tube

nearly 1½ in. long; unopened bud an inch long or less; petals obcordate, broader than long, 1 in. wide; stigmas surrounded by the anthers and self-pollinated in the bud: caps. 1 in. long, loosely aggregated in the lower part of the spike, more densely above, shorter than the subpersistent leafy bracts.—Intro. into Eu. from Amer., and now a common weed in the Old World. Gn. 26, p. 480.—It is somewhat coarse and has little to recommend it to cult., although it is larger-fld. and more beautiful than the common American plants, which, although they are different from the species here described, pass under the name *Œ. biennis*. In France and other European countries, the roots of *Œ. biennis* are said to be used as a vegetable, after the manner of salsify or oyster plant. The root should be eaten, according to Vilmorin, "at the end of the first year of its growth." *Œ. biennis* is now unknown as a wild plant in Amer., although it will probably be found among the numerous locally distributed forms which have not yet been adequately studied. A number of obscure kinds pass in Amer. under the name *Œ. biennis*. Most of them are more weedy than the European species and the roots are generally woody and tough. A var. *hirsutissima* (*Œ. franciscàna*, Bartlett) is offered in Calif., described as having sts. stout and reddish: lvs. hairy, light green, lanceolate: fls. large, bright yellow.

2566. Capsules of evening primrose — Œnothera biennis, as known in North America. (×½)

Var. **grandiflòra**, Lindl. (*Œ. grandiflòra*, Ait.). Plant large and strong: lower lvs. often pinnatifid: fls. much larger, the petals 1–2½ in. long; buds glabrous and usually red-spotted. B.M. 2068. B.R. 1604. Gn. 26, p. 482; 46, p. 64.—Very showy when the fls. open. Commoner southward. Seeds sold under this name are usually the next species.

6. **Lamarckiàna**, Hort. Differs from the above in its densely red-tuberculate sts., broad crinkled lvs. and much larger fls.: the stigmas are longer than the stamens and are pollinated by insects after the buds open: the buds are densely pilose and viscid: the fls. open suddenly about dusk and are immediately visited by the sphinx moths.—This species is unknown in the wild state. It is suspected by some of having had a horticultural origin, but by others considered more probable that it is a wild species which will yet be rediscovered in its native region. It has become the subject of an enormous literature, due to de Vries' discovery that it gives rise to distinct true-breeding derivatives (mutations) in every generation. These mutations are considered to throw light on the vexed question of the origin of species and horticultural varieties. The most interesting of them are a giant form, *Œ. gigas*, and a dwarf, *Œ. nanella*. Others are *Œ. rubrinervis*, *Œ. lata*, *Œ. brevistylis*, and *Œ. oblonga*, whose names suggest the characters in which they differ from the parent species. They are cult. in most botanic gardens, but are not offered by the trade. *Œ. Lamarckiana* closely resembles several beautiful species of the W. which have not been intro. into cult. *Œ. rubricalyx*, Gates, is a derivative of *Œ. Lamarckiana*, from which it differs in having the calyx-tube and segms. a fine rich red. G.C. III. 53:165. It is the only one of the mutations referred to above which has been intro. into general cult. It is known to the trade as "Sutton's Afterglow."

V. SUBGENUS RAIMANNIA.

St.-bearing: stigma deeply 4-cleft; calyx-tube very long and filiform or linear: caps. narrow-cylindric, obtusely 4-angled, with numerous seeds in 2 rows in each locule: fls. yellow, mostly showy.

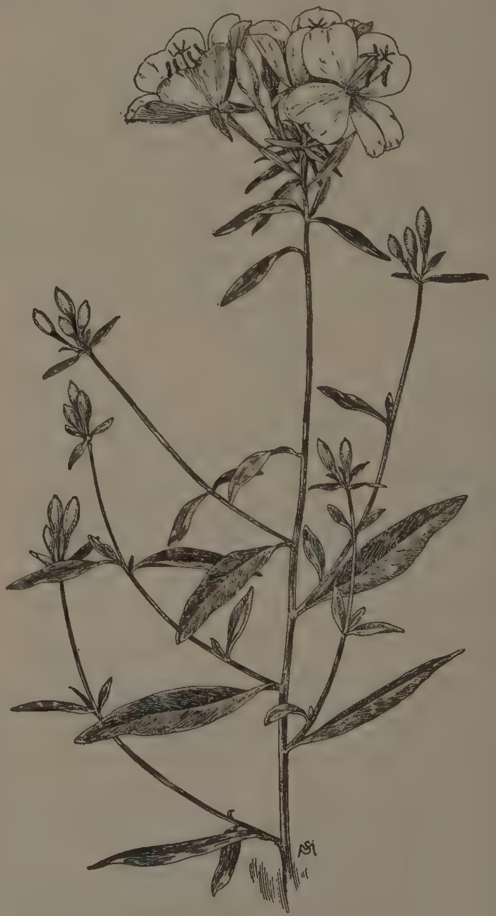
7. **Drúmmondii**, Hook. One to 2 ft., from an oblique or decumbent base, densely soft-pubescent: lvs. lance-oblong or oblanceolate, acute or obtuse, either gradually or abruptly tapering into a short petiole, entire or slightly toothed: calyx-tube usually 2 in. long and very narrow: fls. 2–3 in. across, nocturnal, bright yellow, showy: caps. 1–2 in. long. Texas coast. B.M. 3361.—Perhaps biennial, but grown as an annual.

VI. SUBGENUS ANOGRA.

St.-bearing: stigma deeply 4-cleft; calyx-tube elongated and enlarging upward: caps. oblong or linear: fls. white or pink, opening by day.

8. **albicaùlis**, Pursh (*Œ. pinnatífida*, Nutt. *Ánogra albicaùlis*, Brit.). Annual or biennial, low (1 ft. or less tall), sts. white and shreddy, the branches ascending, slightly pubescent or sparsely hairy: lvs. lanceolate, oblanceolate or lance-oblong, deeply pinnatifid or some of the larger ones only strongly toothed, 4 in. or less long, sessile or nearly so: fls. large (3 in. or less across), diurnal, white and fading to rose, the petals obcordate. Prairies, west.

9. **califórnica**, Wats. (*Œ. albicaùlis* var. *califórnica*, Wats.). Smaller and hoary-pubescent or villous, the sts. only 3 or 4 in. long, ascending from a rootstock:



2567. One of the sundrops—Œnothera linearis. (×½) lvs. narrow-oblanceolate and acuminate, usually stalked, toothed or pinnatifid: fls. often larger, fragrant, the petals lobed. Cent. and S. Calif.

VII. SUBGENUS MEGAPTERIUM.

St.-bearing: stigma 4-cleft; calyx-tube very long and slender, enlarging at the top: caps. very broad and strongly 4-winged: fls. yellow, showy.

10. **missouriénsis,** Sims (*Œ. macrocárpa,* Pursh. *Megaptèrium missouriénsis,* Spach). Low perennial with a hard base, the ascending sts. mostly not over 1 ft. long, usually pubescent: lvs. thick, varying from oval to linear to narrow-lanceolate, 5 in. or less long, acuminate, narrowed to a petiole, entire or remotely denticulate: petals 1–2½ in. long, very broad, yellow: caps. 2–3 in. long and nearly as wide, broad-winged. Mo. and Neb., west and south. B.M. 1592. Gn. 26, p. 480. R.H. 1857, p. 598.

11. **Hávardii,** Wats. Sts. numerous, short, slender and simple or branching, rising from a branching caudex, the plant canescent: lvs. linear-lanceolate in a rosette, narrowed toward either end, sinuate-pinnatifid: fls. sessile, the buds erect, the calyx-tube with coherent tips; petals ½–1 in. long, yellow turning red: caps. oblong-ovate, 4-angled and ribbed. Texas.

VIII. SUBGENUS KNEIFFIA.

St.-bearing: stigma deeply 4-lobed; calyx-tube very slender, somewhat dilated at the top: caps. rather small, club-shaped, 4-angled or narrowly 4-winged: fls. yellow, diurnal.

A. *Plant more or less glaucous, glabrous.*

12. **glaùca,** Michx. (*Kneìffia glaùca,* Spach). Erect perennial, 2–3 ft.: lvs. ovate to ovate-oblong, 4 in. or less long, acute or somewhat obtuse, sessile, remotely denticulate: fls. large, in short leafy clusters, the calyx-tube about ¾in. long; petals an inch long, more or less emarginate: caps. oblong, broad-winged, short-stalked, Va., Ky., and south. B.M. 1606. Var. **Fràseri,** Torr. & Gray (*Œ. Fràseri,* Pursh), is a form with ovate-lanceolate often slightly petioled lvs. Southern states. B.M. 1674.

AA. *Plant not glaucous, usually hairy or pubescent.*

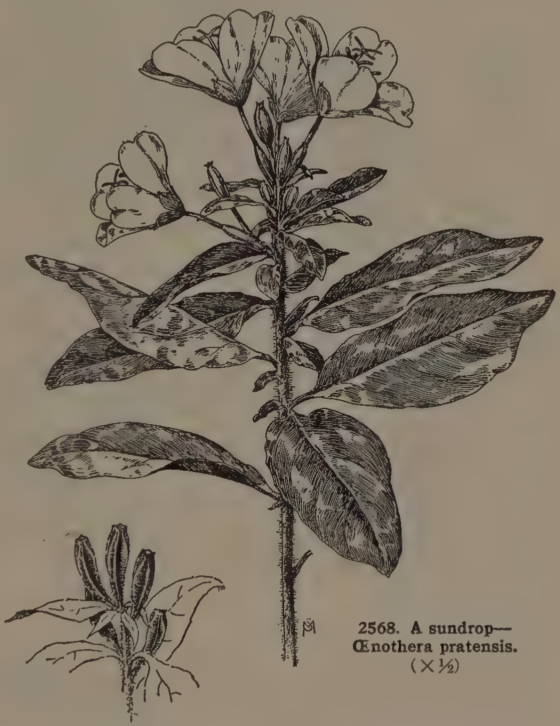
B. *Caps. smooth, or bearing slight gland-tipped hairs.*

13. **fruticòsa,** Linn. (*Kneìffia fruticòsa,* Raim.). Sundrops. Perennial (or sometimes biennial), erect and more or less branchy, rather stout, 1–3 ft. high, the terete usually reddish sts. somewhat villous: lvs. ovate to narrow-lanceolate, 3 in. or less long, firm, usually acute, remotely denticulate or entire, mostly sessile: fls. 1½–2 in. across and showy, in an elongating cluster, with linear bracts: caps. oblong to obovate, short-stalked or sessile, strongly winged. Dry soil, Nova Scotia, south and west. B.M. 332.—Very variable. Var. **Yoùngii,** Bailey (*Œ. Yoùngii,* Hort.), is common in cult., and is prized for its stocky growth and profusion of bloom. It is a strong larger-lvd. plant, with firm shiny slightly glaucous foliage, and bearing many bright lemon-yellow fls.: 2 ft., much branched and somewhat decumbent at base. Excellent. Var. **màjor,** Hort., is a strong-growing floriferous form, forming a dense bush-like specimen.

14. **pùmila,** Linn. (*Kneìffia pùmila,* Spach). Sundrops. Slender erect biennial or perennial, 1–2 ft. high, simple or branched: lvs. oblanceolate or oblong, usually glabrous, entire, the radical spatulate: fls. an inch or less across in a loose, leafy spike or raceme, the calyx-tube shorter than the ovary, the petals obcordate: caps. mostly clavate, short-stalked or sessile. Newfoundland, south and west. **Œ. Pìlgrimii,** Hort., appears to belong with this species. It is very like *Œ. fruticosa* var. *Youngii* horticulturally, but in established plants it is apparently somewhat taller and more branching, and the fls. not so large and color not so deep; it may be an offshoot of *Œ. fruticosa.*

BB. *Caps. grayish pubescent, the hairs glandless.*

15. **lineàris,** Michx. (*Œ. fruticòsa* var. *lineàris,* Wats. *Kneìffia lineàris,* Spach). Sundrops. Fig. 2567. Slender, 12–20 in. high, biennial or perennial, pilose, puberulent or nearly glabrous: basal lvs. spatulate to broad-oblanceolate; st.-lvs. linear to narrow-lanceolate: fls. bright clear yellow, 1½ in. or more across, standing well above the foliage lvs.; petals obovate and notched or emarginate at apex: caps. mostly less broadly winged, clavate. Conn., south. Gn. 26, p. 481.—In cult., this is a neat and bright little plant, blooming in July. The plant known in gardens as *Œ. fruticosa* var. *pallida* probably belongs with this species or with the form of it sometimes separated as *Kneìffia Állenii,* Small.



2568. A sundrop—Œnothera pratensis. (×½)

16. **praténsis,** Rob. (*Kneìffia praténsis,* Small). Fig. 2568. Sundrops. A day-blooming perennial, 1–3 ft. high, making a good clump and frequently planted in yards: sts. sometimes branched above, with soft-spreading hairs: lvs. oblong-lanceolate to elliptic-lanceolate, hairy, entire or sinuate, acute or obtuse: fls. bright yellow, leafy-bracted, mostly clustered at top of st.; tips of calyx hirsute; petals ½–1 in. long, obcordate: caps. club-shaped, hispid, sessile or nearly so. Maine to Iowa and Ark.—A good hardy plant for early summer to midsummer bloom.

IX. SUBGENUS HARTMANNIA.

St.-bearing: stigma 4-lobed; calyx-tube funnelform, often very long: caps. club-shaped or obovate, broad-winged: fls. white, pink or red, diurnal. (Including Xylopleurum, etc.).

A. *Plant canescent or villous, usually erect, or at least prominently ascending.*

17. **speciòsa,** Nutt. (*Hartmánnia speciòsa,* Small). Perennial, with a rootstock, erect or ascending branches, 2 ft. or less high, canescent: lvs. linear to lance-oblong, 4 in. or less long, remotely or sinuately dentate, or the

lower ones pinnatifid, attenuate at base: calyx-tube as long as the ovary; petals large, obcordate, white: caps. ½–¾in. long, 8-winged, acute at top. Mo., west and south. B.M. 3189. Gn. 26, p. 482.

18. **tetráptera,** Cav. (*Hartmánnia tetráptera*, Small). Villous: caps. larger and more broadly winged, very abruptly contracted at top: calyx-tube shorter than the ovary: fls. white, becoming rose. Texas and Ariz., south. B.M. 468. Var. **Childsii,** Bailey (*Œ. ròsea mexicàna*, Hort.), is a handsome form intro. from Texas by John Lewis Childs in 1892. It was found in the wild. "We first secured the pink," Childs writes, "and afterwards someone else sent us the white, blush and the other shades, all from Texas." In some respects it differs markedly from *Œ. tetraptera*, and it is not impossible that it is a distinct species. In cult. it is a trailing plant. The lvs. tend to be broader and less pointed than in *Œ. tetraptera*. It does not produce seed in the N., but is readily prop. by cuttings. It is an excellent plant either for the flower-garden or for pots in the conservatory. It is popularly known as the "Mexican evening primrose."

2569. Okra. The pods of okra vary greatly in length, depending on the variety, up to 10 and 12 inches; they are usually 4 to 6 inches long. (×½)

19. **ròsea,** Ait. (*Hartmánnia ròsea*, Don). Root biennial or perennial: st. erect or ascending, 1–2 ft., branching from the base: lvs. lanceolate to narrow ovate-lanceolate, mostly acuminate, rather abruptly narrowed to a petiole, entire or remotely denticulate or the larger ones small-lobed at the base: calyx-tube shorter than the ovary: fls. small, fuchsia-like, purple or rose, the petals rounded and entire: caps. much like that of *Œ. speciosa*. Texas and New Mex., south. B.M. 347.

AA. *Plant glabrous or essentially so, nearly stemless or else prostrate.*

20. **acaùlis,** Cav. (*Œ. taraxacifòlia*, Hort.). Tufted perennial or biennial plant, at first stemless, but producing prostrate, somewhat zigzag sts.: lvs. oblong in outline, 5–8 in. long, petioled, divided into many unequal narrow divisions (like a dandelion lf.): fls. usually opening white, but changing to rose, large (2–3 in. across), the very slender tube 3–5 in. long: caps. short-obovate, broadly triangular-winged above. Chile. B.R. 763. Gn. 26, p. 480.—A very interesting and attractive plant.

X. SUBGENUS PACHYLOPHUS.

Stemless or essentially so: stigma 4-cleft; calyx-tube very slender but enlarging upward, longer than the ovary: caps. with wrinkled or contorted wings: fls. white or pink.

21. **cæspitòsa,** Nutt. (*Pachýlophus cæspitòsus*, Spach). Crown 2–4 in. high, perennial or biennial: lvs. clustered, oblong to narrow-lanceolate or spatulate, sometimes 1 ft. long, attenuate, repand-toothed, pubescent: fls. white or pink, 1⅓–3 in. across, the petals obcordate; calyx-tube 2–6 in. long: caps. oblong-pointed, 1–2 in. long. S. Dak., Neb., west and south. B.M. 1593, 5828 as (*O. marginata*). Gn. 26:480; 47, p. 46 (both as *O. marginata*).

XI. SUBGENUS LAVAUXIA.

Stemless or essentially so: calyx-tube very slender, enlarging upward, longer than the ovary: caps. with plane or entire wings: fls. white, pink, or even pale yellow.

22. **brachycárpa,** Gray (*Lavaùxia brachycárpa*, Brit.). Perennial, densely pubescent: lvs. thickish, ovate to very narrow-lanceolate, about 6 in. long, long-stalked, entire or notched or lyrately pinnatifid; calyx-tube 2–3 in. long; petals about 1½in. long, purplish: caps. ovate, often 1 in. long, the wings not wrinkled. Mont. to Kans., west and south.

Œ. Árendsii, Bowles. Said to be a hybrid of Œ. speciosa and Œ. rosea, ("Œ. speciosa var. rosea") hardier than the former: spreads freely from the base, blooming on the young shoots: fls. large, delicate shade of pink with white eye. Gn. 76, p. 638.

L. H. B.

OKRA, or GUMBO (*Hibiscus esculentus*) is a half-hardy plant introduced into United States and West Indies from Africa, and cultivated for its fruit-pods, which are used in soups, stews, catsups, and the like (Fig. 2569). In soups and catsup, it gives body to the dish; stewed, it is mucilaginous, and while at first not agreeable to many persons, a taste for it is easily acquired. It is also dried and canned for winter use. When ripe, the black or brown white-eyed globular seeds are sometimes roasted and used as a coffee substitute.

Okra should be sown in a dry warm soil, of medium fertility and texture, after danger of frost has passed. It is important to select the correct type of land for growing okra. It should be a well-drained sandy loam, or if clay only is available it should be a loamy clay, and a soil that is not likely to become water-logged during the rainy weather. The soil should be prepared deeply and thoroughly, the deeper the better, if the soil is good. The rows should be made 3 to 5 feet apart, according to variety, and seeds dropped about 2 inches apart in the row; cover 1 or 2 inches deep. After plants are 6 inches high, thin to 1 foot apart for dwarf varieties and to about 3 feet for the largest varieties. After the plants have been cut out to a proper stand in the row, frequent cultivation should be given. This is best performed with implements that cut rather deeply. The okra plants do not throw out many lateral roots in the early stages of growth if planted on the proper kind of soil. The seedlings transplant with considerable difficulty, so they need to be started in flower-pots if an extra-early crop is desired. The pods must be gathered before the fiber develops in them: the size will vary with the variety, but if it is too "stringy" to cut with a dull case-knife it is too old. Keep all old pods cut off. The dwarf varieties are in greater favor in the South because of their habit of bearing early. A plant, constantly cropped, remains in bearing condition until frost kills it, but allowed to retain pods it suspends growth until the seeds have matured, when a second growth may take place. Okra will grow for years if not killed by frost or other adverse conditions, i. e., it makes an indeterminate growth like cotton, malva, hibiscus, and the like. For shipping, cut the stems (peduncles) an inch or so long so as to prevent wilting in transit. Pack firmly in vegetable crates. The demand for this vegetable is increasing, especially in New York City. Seed is easily grown and saved. The plant is subject to several diseases to such an extent that it is impracticable to raise a crop on certain pieces of land. Rotation is the best remedy. P. H. Rolfs.

ÒLAX (probably from the odor or smell). *Olacàceæ.* Thirty and more species of trees, sometimes scandent, shrubs and subshrubs in the tropical parts of the Old World, little known in cult.: lvs. alternate, simple: fls. white or whitish, sometimes colored, small, mostly in short axillary simple or branched racemes; calyx cup-shaped, minute; petals 3–6, some of them in some species coherent; fertile stamens usually 3, sometimes 4 or 5, mostly standing opposite the edges of the petals; staminodia 5 or 6, notched, mostly standing opposite the petals; ovary free, in a cup-shaped disk, the stigma 3-lobed: fr. somewhat immersed in fleshy calyx, containing a 1-seeded stone. None of the species seems to be listed; probably some of them would be interesting far S. L. H. B.

OLDENBÚRGIA (S. Oldenburg, a collector for Kew in 1772–3). *Compósitæ.* Three species of remarkable S. African stocky shrubs or subshrubs, with woolly rootstocks, and large solitary heads of purple corollas. They are not in general cult., but may be expected in some of the botanical collections: lvs in a rosette, coriaceous and 1-nerved, very hairy underneath: fls. all perfect in the head, the outer ones radiate; scales of involucre linear, acuminate, not spiny: achene beakless, with a pappus of many plumose bristles. *O. Árbuscula,* DC., has flowered in recent years in England (at Kew the plant was 3 ft. high and unbranched at 16 years): lvs. crowded at ends of branches, obovate or oblong, to 18 in. long, at first white-woolly: fl.-heads often 1 ft. across, purple and white. B.M. 7942. G.C. III. 35:9. L. H. B.

OLDENLÁNDIA (H. B. Oldenland, Danish botanist, of the 17th century). *Rubiàceæ.* More than 200 species of shrubs, subshrubs and herbs in many parts of the world, mostly tropical, of little value horticulturally. Fls. small, most inconspicuous, white or rose-colored, rarely solitary but mostly in dichotomous panicles; calyx mostly 4-toothed; corolla usually 4-toothed, rotate, funnel-shaped or salver-shaped; stamens mostly 4, inserted in the throat of the corolla: fr. a small caps. adnate to calyx-tube, dehiscent at top: lvs. opposite, mostly small and narrow. A few annual or perennial species are native in N. Amer., being small plants of no prominence. L. H. B.

OLDFIÈLDIA (from R. A. Oldfield, a merchant at Sierra Leone). *Euphorbiàceæ.* Evergreen tropical tree rarely cult. in greenhouses: lvs. opposite, digitately compound; lfts. 5–7, entire, coriaceous, pinnately veined: fls. diœcious, apetalous, in short axillary clusters; stamens 4–10; ovules 2 in each cell. Related to Bischofia. One species in Trop. Afr., *O. africàna,* Hook., is said to yield the African oak, or African teakwood, sometimes exported. It may be grown from cuttings in loam, leaf-mold and sand and should be well watered when growing rapidly. J. B. S. Norton.

OLD MAN. Another name for the southernwood, *Artemisia Abrotanum;* also for the rosemary, *Rosmarinus officinalis;* and probably for various hoary plants. *Artemisia Stelleriana* is said to be known sometimes as Old Woman.

OLD-MAN-AND-WOMAN, or common houseleek: *Sempervivum tectorum.*

OLD MAN CACTUS: *Pilocereus senilis.*

OLD MAN'S BEARD. In Europe, *Clematis Vitalba;* in America the common wild clematis, *C. virginiana;* also *Saxifraga sarmentosa;* rarely the fringe tree, Chionanthus.

ÒLEA (classical name for olive). *Oleàceæ.* Olive. The olive tree and fruit; and other small trees or shrubs of little importance in cultivation. (The *Olea fragrans* of greenhouses is Osmanthus; also *O. Aquifolium.*)

Spiny or unarmed: lvs. evergreen and thick, opposite, usually entire, and often rusty-tomentose beneath: fls. small, usually imperfect, white or whitish, in forking panicles or fascicles, the short calyx 4-toothed (corolla sometimes none), the short-tubed corolla with 4 valvate lobes, the stamens 2; ovary 2-loculed, bearing a short style and capitate stigma: fr. an oblong or ovoid drupe.—Between 30 and 40 trees or shrubs of the tropical and warm-temperate parts of the Old World to New Zeal.

europæ̀a, Linn. Small tree, rarely exceeding 20 or 25 ft. in height, and bearing small oblong or lanceolate lvs. and axillary forking racemes of yellowish white fragrant fls. It is probably native to the E. Medit. region or W. Asia, but has been in cult. from the earliest times and is spontaneous in parts of S. Eu.

Var. **Oleáster,** DC. (*O. Oleáster,* Hoffm. & Link. *O. sylvéstris,* Mill. *O. europæa* var. *sylvéstris,* Rouy). The wild form: thorny, the branches 4-angled or -cornered: lvs. elliptic or oblong: fr. small, roundish, inedible.

Var. **commùnis,** Ait. (*O. gállica,* Mill. *O. officinàrum,* Crantz. *O. lancifòlia,* Moench. *O. sativa,* Hoffm. & Link. *O. europæa* var. *sativa,* DC.). The cult. olive, a handsome gray-green tree, with thornless terete or only obtuse-angled branches: lvs. lanceolate, willow-like in shape: fr. size of a damson or larger, nearly globular to oblong. See *Olive.*

chrysophýlla, Lam. Small tree, noteworthy because of the drab or golden color of the under surface of the lvs.: branchlets slender, lepidote or scurfy upward: lvs. lanceolate, 2–4 in. long, the petiole very short: fls. small (corolla ⅛in. long), in axillary panicles: drupe rather large and blackish, globose or somewhat long. Trop. Afr.—It has been intro. to cult. in S. Calif. L. H. B.

OLEANDER: *Nerium Oleander.*

OLEÀRIA (J. G. Olearius, who published a flora of Halle, 1668). *Compósitæ.* Tree-Aster. Shrubs and trees of Australia and New Zealand, allied to Aster, somewhat planted abroad, but apparently not tested in this country.

The tree-asters are of more than 100 species, evergreen, with white, blue or purple rays, many of which are worthy of cult.: lvs. alternate, or sometimes opposite or fascicled, mostly tomentose beneath: heads various in size, solitary or clustered, sometimes rayless, the involucre with several rows of bracts that have scarious or dry margins; ray-florets female, in a single row; disk-florets perfect: achene terete or somewhat compressed, bearing one or more rows of pappus bristles. Some of the New Zealand species have large usually solitary fl.-heads and stiff lanceolate toothed lvs., which should be tested in Amer.; Cockayne writes that they require a moist equable climate with low summer temperature, and are not suited to ordinary garden conditions. Speaking of the New Zealand olearias in general, of which there are more than 40 species, Cockayne says that all are well worthy of cult.; some are alpine and subalpine; some are both trees and shrubs, others shrubs alone.

Haàstii, Hook., long known in south of England as a good late summer- and autumn-blooming shrub and apparently the only one that has been regularly offered in this country: in New Zeal., where it is native (in the south island), a shrub 4–8 ft. high, with hoary branches:

lvs. alternate, oblong, elliptic or oblong-ovate, 1¼ in. or less long, shining above and tomentose beneath: heads small and numerous, containing 8–10 florets, and 3–5 short broad white rays. B.M. 6592. G.C. III. 20:533. Gn. 38, p. 149; 78, p. 473. J.H. III. 68:265. F. 1874, p. 198. R.H. 1913, pp. 495, 497.

Other recent accessible portraits of olearias as cult. plants are: *O. chathamica*, Kirk, G.C. III. 53:363; *O. Forsteri*, Hook. f., G. 35:515; *O. insignis*, Hook. f., G.C. III. 57:333. Gn. 79, p. 301. G. 37:283. *O. macrodonta*, Baker, G. 35:443, 445; O. *myrsinoides*, Muell., Gn. 77, p. 58, the Australian daisy-bush blooming in England in June; *O. nitida*, Hook. f., G.M. 56:692. G. 35:757; *O. semidentata*, Decne., B.M. 8550; *O. stellulata*, DC. (*O. Gunniàna*, Hook. f.), B.M. 4638. Gn. 78, p. 350. R.H. 1913, p. 547.

L. H. B.

OLEASTER: *Elæagnus angustifolia;* also *Olea.*

OLFÉRSIA (after Ignaz Olfers, a German consul at Rio Janiero). *Polypodiàceæ.* A genus of one species related to Polybotrya, formerly classified with Acrostichum. Fertile and sterile lvs. dissimilar, the sterile 2-pinnate, the fertile 3-pinnate, with the sporangia in masses completely covering the backs.

cervìna, Kunze. A showy large fern adapted for cult. on palm trunks, and the like: rootstock creeping, densely clothed with long narrow scales, the lvs. 3–6 ft. long, 10–20 in. broad, coriaceous, with prominent veins which unite at the margins. R. C. Benedict.

OLIGOBÒTRYA (*few clusters*). *Liliàceæ.* One species, in China, intermediate between Smilacina and Polygonatum. It is an erect herb, 3 ft. and more tall, adapted (in England) to a shady moist border such as is suited to hardy cypripediums. *O. Hénryi*, Baker, is the species: lvs. ovate-oblong or ovate, alternate, sessile or short-stalked, many-nerved, pubescent, about 4 in. long: fls. white or pale yellow, in terminal simple or branching racemes; perianth-tube cylindric, ⅓in. long, the 6 broad lobes shorter and spreading; stamens joined to throat of corolla, the filaments very short; ovary ovoid, the stigma 3-lobed. B.M. 8238. Var. *violàcea*, C. H. Wright, has a violet perianth-tube and paler lobes. B.M. 8238.

OLIVE. A small evergreen tree grown for its drupes which yield oil and are also prepared as a food and condiment.

The cultivated olive (*Olea europæa*) is the typical species of the genus Olea (Fig. 2570). It is found growing wild in various countries from the Punjab to Morocco and the Canary Islands and on both sides of the Mediterranean from the slopes of the Atlas to southern France and Macedonia where moisture and temperature conditions are favorable. It is particularly abundant in Syria and Algeria. The wild form has small rigid leaves and a fruit with little flesh and is sometimes considered as a distinct botanical variety under the name of oleaster or *Olea sylvestris* (see *Olea*). It is used as a stock on which to graft the cultivated forms and in Algeria the government encourages the utilization of wild trees by grafting in place (Fig. 2571).

2570. Olive in flower and fruit.

The cultivated olive is grown throughout the same region and, with the aid of irrigation, in localities too dry for its naturalization. It has been grown from prehistoric times in Asia Minor where it seems to have originated. Its culture was introduced into all Mediterranean countries by the Phœnicians, Greeks, and Romans. In modern times it has been widely dispersed by colonists in America, Australia, and South Africa.

In the United States the olive succeeds only in California and in parts of Florida, Arizona, and New Mexico. It was planted at the missions by the Franciscan padres and from the trees grown there came the variety now known as the Mission, which is still preferred to all other varieties by most growers. The original trees were grown at the San Diego Mission from seeds brought from Mexico. Like the Mission grape, the Mission olive has not been identified with any Old World variety and is probably a seedling. Some growers distinguish several forms or variations of the Mission, differing in size and form of leaf, fruit, and tree. The correctness of this view seems probable from the mode of its origin, but others consider these differences to be due simply to variations of soil and climate.

The olive thrives in all soils providing they are deep and well drained, but the crops are in proportion to the fertility of the soil. The olive will often make a handsome vigorous tree in dry situations unsuited to most fruits, provided the subsoil will allow of deep penetration of the roots. Paying crops are obtained, however, only on fairly fertile soil and with intelligent and thorough cultivation. It requires a slightly greater annual sum of heat than the vine and is more sensitive to winter cold, which should never fall below 14° F., nor frequently below 19° F. A clear dry atmosphere is favorable. Summer rains or fogs render the tree subject to the attack of the black scale, which is very harmful and difficult to control on the olive.

Suitable situations and paying orchards are found in California from the upper end of the Sacramento Valley to the borders of Mexico in Imperial County. Most of the paying orchards are on the slopes of the Sierras at moderate elevations, in southern California, and widely scattered through both the Sacramento and the San Joaquin valleys. There are a few good orchards in favored locations in the inner coast valleys from Sonoma southward. Olive-growing promises to be very successful in the Imperial Valley.

The suitability of California for olive-growing began to be generally recognized between 1880 and 1890 and many orchards were planted during this period. The expectations of large profits were not as a rule realized when the trees came into bearing. Several causes contributed to this. The oil could not compete with the cheap cottonseed oil which was often sold as "pure olive oil;" the ripe pickled olives were a novelty and their merits not understood in the East and the first attempts to manufacture green pickled olives were unsuccessful. Many orchards were accordingly uprooted and few trees were planted during the next fifteen years. Recently effective pure-food laws have removed much of the competition of imported and domestic cottonseed oil, the taste for ripe pickled olives has been acquired by a large body of consumers and the methods of producing green pickles have been perfected. Few of the last, however, are made, as the demand for good ripe pickles exceeds the supply. Olive-growing has therefore been on a profitable basis for some years and large new plantations have been made during the last five years.

No reliable statistics of the olive industry are available but the statistician of the California State Board of Agriculture places the number of trees in California at 1,530,000 which corresponds to something under 30,000 acres. The same authority credits Florida with 8,000 trees, Arizona with 1,600 and all other states with 200. The State Board of Equalization, however, placed the number of trees in California in 1912 at only 700,000, or about 14,000 acres.

It is estimated that California produced in 1910 about 800,000 gallons of olive oil and 1,000,000 of pickled olives. For 1911, the oil output is placed at 920,000 gallons and the pickles at 1,150,000 gallons. If one ton of olives is reckoned to yield thirty-five gallons of oil and that it requires six pounds of olives to make one gallon of pickles, the crop of 1911 represents about 31,000 tons of fruit, of which 85 per cent were used for oil and only 15 per cent for pickles. If the average of the estimates of total acreage given above is taken, the crop is equivalent to 1.4 tons to the acre. When it is considered that many orchards are planted with poor bearing varieties and in unfavorable situations, this average is satisfactory.

2571. Arab family gathering fruit of grafted wild olive in Algeria.

According to the state statistician, six counties of the San Joaquin and Sacramento valleys produced in 1900 nearly 75 per cent of the crop of the whole state, though having but 25 per cent of the trees. This indicates a variation of crop of less than half a ton to over four tons to the acre, according to locality. In the south of France 2.7 tons to the acre is considered a maximum yield and good well-cultivated orchards are not expected to average more than 1.3 tons.

Using the estimates given above, it will be seen that pickles were made from only about 15 per cent of the crop, the remainder being used for oil. The reason for this is that while pickled olives of suitable quality are more profitable than oil, only the large olives are acceptable to the market. During the first period of heavy planting, a large number of the trees used were of varieties suitable for oil, which are all of small or medium size. Even when large-fruited varieties are planted, there will always be a large proportion of the fruit undersized, especially in poor soil and in unfavorable localities. At present the tendency is to plant only those varieties which are capable of producing large fruit but which at the same time are rich in oil of good quality. The pickled olive is thus considered the main crop and the oil a kind of supplementary or by-product. From this point of view, the Mission olive, when propagated from selected trees in favorable localities, is perhaps the best variety. Pickling and oil-making tend to concentrate in large central establishments in each olive-growing center. This makes it possible to employ the best methods and machinery in the hands of trained men. The results are great improvement in quality of the product and economy of operation.

The price paid for olives fell at one time to $15 a ton which, with the average crop, represents gross returns of $25 or $30 an acre, which in most cases would not pay the cost of cultivation and harvesting. It has risen gradually until during the last few years $100 a ton has been paid for olives suitable for pickling and even $150 to $200 a ton for very large fruit. This represents average gross returns of about $150 or more to the acre and is very profitable, as the large olives are gathered much more cheaply than the small. When turned into pickles, a ton of olives represents $250 at the low retail price of 75 cents a gallon, but a ton of olives will yield oil of a value of only about $87.50 at the ordinary price of $2.50 a gallon. As olives are usually bought ungraded, the buyer of pickling olives at present prices incurs a loss on all the small olives he uses for oil. The price paid for oil olives too small for pickling is less than half that paid for the large fruit.

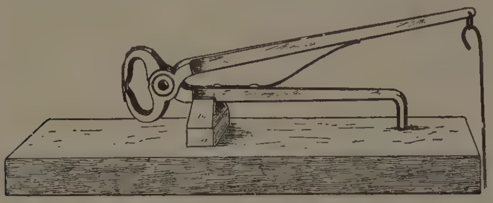
Propagation.

Olives in California are usually grown from cuttings taken from the tree when it is most dormant, that is, in January and February. These cuttings may be of any size and taken from any part of the tree. Most nurserymen prefer to use "tips." These are the mature ends of shoots 4 to 5 inches long. Two or three of the upper leaves are left or trimmed back a little and the remainder removed entirely. They are then planted in boxes of sand under glass with artificial heat and, after rooting, transplanted to the nursery where they remain for one, two or three years before being planted in place. When a greenhouse is not available, larger cuttings of older wood are preferable. These cuttings are usually made about 14 inches long and may be from ¾ to 1½ inches in diameter. Their rooting may be facilitated by splitting or scratching the bottom 2 or 3 inches with a knife. In Spain, large branches of old trees are used to produce young plants. These branches (truncheons) are cut into convenient lengths and incisions reaching half way to the center made every 3 or 4 inches. The sections are then placed horizontally in trenches about 10 inches deep, where they are covered with soil, and watered. Shoots arise near the saw-cuts and when sufficiently developed they are removed with the roots which have formed, and planted in the nursery. This method, formerly employed in California, is now little used there. Suckers taken from the base of the trunk with a plate of the old wood attached to the base are sometimes used and root more easily than ordinary cuttings.

Olives may also be propagated by seeds, which are supposed to give a stronger root-system and more fruitful trees. The seedlings, however, must be grafted and it takes a little longer to obtain a tree by this means.

The Mission and many other cultivated varieties have large seeds which are hard to germinate. Small-fruited varieties, such as the Redding and Chemlali, which resemble the wild olive, are the best. The completely ripe olives are placed in a heap until the pulp becomes soft enough to be removed easily. Usually the stones are then treated for twelve to twenty-four hours in a 10 per cent solution of caustic soda. The process must be carefully watched by breaking a stone occasionally and the lye removed before it penetrates to the kernel. The treated pits are kept in moist sand until March or April, when they are planted thickly in close rows. Many will not germinate the first year and many not at all.

Much time may be saved by clipping off the apex of the olive pit. Seeds treated in this way will germinate readily in a few weeks. By means of a simple device originated by the California Experiment Station, this clipping can be done very rapidly (Fig. 2572).



2572. Device for clipping olive seeds.

The second or third year, the young seedlings are transplanted to nursery rows in good rich soil, where they are budded or grafted the following spring. One or two years later, they are ready to be planted in the orchard.

The planting distances vary with the nature of the soil and of the variety. The trees in some orchards are planted as near as 20 feet, but more at 24 to 30. The olive is very long in reaching its full size, and some growers plant at 20 or 24 feet with the intention of taking out three-quarters of the trees when they begin to crowd, leaving them 40 to 48 feet apart. It is not, however, until the trees are twenty-five or thirty years old that they reach full size, and most growers prefer to plant at intermediate distances of about 30 to 36 feet. In France, the distances adopted vary from 15 feet in the most northerly districts to 24 feet in the more southerly. In Algeria, from 30 to 36 feet are the usual distances, while in Tunisia 45 feet and even 60 to 72 feet are adopted, usually with intercalary annual crops. Most of the olives in California are planted in solid orchards, but many are used as avenue and border trees.

Seedling olives are grafted in the nursery. This may be done when the seedlings are one year old, by means of a side- or whip-graft in early spring, or of a twig-bud after the sap is flowing freely. The graft is made at or near the surface of the ground. Older seedlings may be crown-grafted or twig-budded higher up in late spring. Old trees may be grafted to change to a more desirable variety. Much grafting of this kind has been done in California, the large pickling varieties being grafted on small oil olives or on the strong-growing Redding, which bears a worthless fruit and was at one time planted largely in the mistaken belief that it was the large-fruited Picholine. The trees may be cut back to the main branches and crown-grafted immediately or allowed to form a growth of new shoots, which are budded the following year. Much care and work are necessary for several years to prevent the growth of suckers from the old stocks.

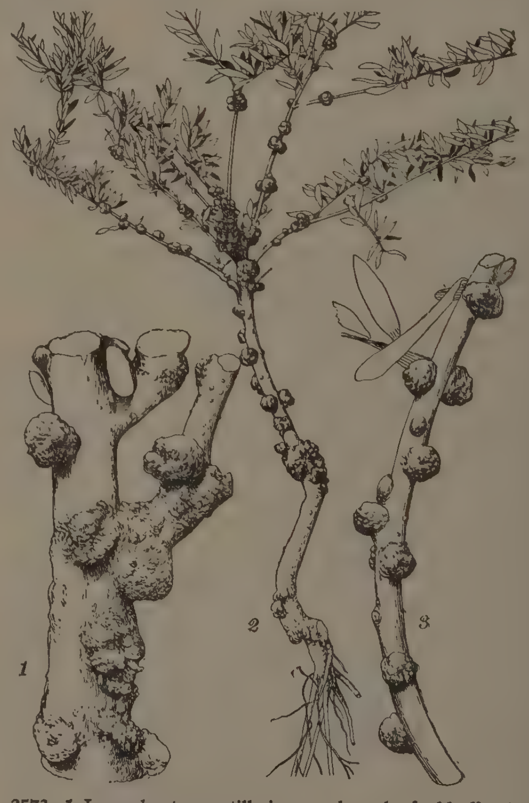
Cultivation and pruning.

The planting and cultivation of the olive require the same care as in the case of other fruits. Where the rainfall is ample, thorough cultivation may insure sufficient soil-moisture, but in most cases irrigation is necessary. Cutting back and the removal of ill-placed branches is advisable during the first and second years, and the tree should be allowed to make only one trunk. After the second year, the lower branches should be gradually removed until a clean trunk of 2 or 3 feet is formed. Cutting back and thinning out of the branches should be practised at every winter pruning in order to give the tree the required symmetrical arrangement of branches. For trees which tend to become close and compact, thinning out of branches is chiefly needed; for those which tend to become weak and elongated, more cutting back is necessary.

By the fifth or sixth year, the framework of the tree should be formed and paying crops produced. The methods of pruning bearing trees vary greatly in various countries. In many, a very severe cutting-back is practised every other year and, as a consequence, the olive bears only on alternate years. The origin of this custom seems to have been due to the olive-fly and scale, which can be fairly well controlled by this means. Trees which are not pruned at all also tend to bear only every other year and to have small inferior fruit. As the olive bears only on the two-year-old wood, like the peach, annual pruning is necessary for annual crops.

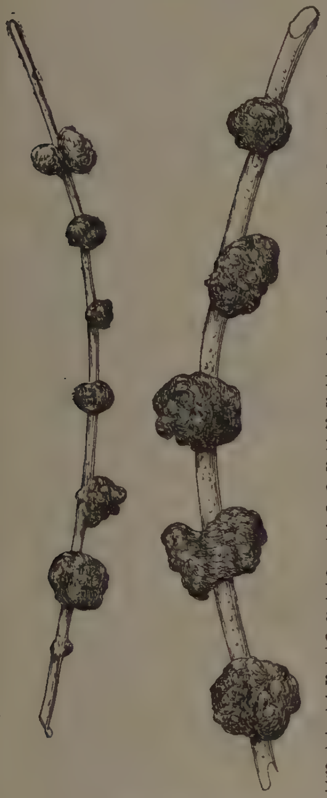
The most approved method in California is an annual pruning which consists principally of thinning out from one-third to one-half of the small branches. As much as possible of the removals should be of branches which have borne the preceding year, especially those which have made little new growth. Injured or ill-placed branches are removed and the fruiting surface spread as uniformly over the tree as possible. Vigorous trees should be pruned less than those which are weak and removals made in such a way that light and air reach every part of the bearing wood.

Thorough clean cultivation is needed by the olive and is practised as with other orchard-trees in California. The olive will live with less water than most orchard-trees, but for the production of good crops of large fruit an abundant water-supply is necessary. When the moisture is inadequate, the blossoms do not set well and the fruit is small. Most of the paying orchards are irrigated. Frequent and shallow irrigations are unfavorable to the health and bearing of the



2573. *1*, Large knots on still vigorous branch of old olive tree. *2*, Young tree planted to replace one destroyed by knot. *3*, Small knots on much weakened branch.

tree. Heavy winter and spring irrigations followed by thorough summer cultivation are usually sufficient, though a supplementary watering just before blossoming time (March to May) and one when the fruit is almost of full size are useful in many soils and locations.



2574. Tuberculosis of olive.

Diseases and insects.

The only serious disease which attacks the olive in California is the "olive-knot." This disease is characterized by numerous knots or tumors on the leaves, twigs, branches and trunk, varying in size from ⅛ inch to 1 or occasionally 2 inches (Figs. 2573, 2574). When badly attacked, the tree is much weakened and, in extreme cases, killed or rendered unprofitable. The disease is infectious and caused by specific bacteria (*Bacterium savastanoi*). Though found in several widely scattered districts, few orchards have been seriously injured and it seems probable that its spread can be controlled by quarantine. It is most harmful to young trees and in rich moist soils of the warmer districts. Eradication by means similar to those used for pear blight seems possible.

A fungous disease of the leaves (*Cycloconium oleaginum*) occurs, but is not important. Rarely, susceptible varieties are slightly weakened by an unusually heavy attack. Fungous decays of roots and stem have been noted, but do little damage as a rule. Old olive trees in Europe often bear satisfactory crops even after a great part of the interior of the trunk has decayed (Fig. 2575).

The black scale (*Saissetia oleæ*) is very injurious to the olive in the moister regions of the coast ranges, in some parts being so prevalent as to prevent the profitable growing of the tree. In the dry summer air of the interior the scale is absent or not injurious. The noxious olive-fly and olive-moth of Europe do not exist in California.

Harvesting.

The stage of maturity at which the olives are harvested depends upon the use that is to be made of them. For green pickles, they should be gathered as soon as or just before they have reached full size and before they show the slightest change of color. Only at this stage is it possible to preserve the clear yellowish green which the consumer demands and which insures the best price. In ripe pickles, the consumer demands a deep uniform shade as nearly black as possible. Different varieties of olives vary considerably in the amount of coloring matter they contain, but in all varieties it develops its full intensity only at full maturity. As the olives on a tree do not all ripen together, it is customary to wait until nearly all have developed a good black color. If gathered too soon, many will bleach to yellow or red in the pickling process; if left too long many will become too soft. Both these difficulties can be overcome to a large extent by modifications in the methods of pickling.

When used for oil-making, the quality and quantity of the oil will vary according to the degrees of ripeness of the fruit, when gathered. The maximum quantity is obtained by harvesting the olives when they are completely mature and soft. There is an increase in the percentage of oil afterward, due to a partial drying of the fruit, but no increase in the total quantity of oil. The finest and most highly prized oil is made from olives gathered just before they begin to soften.

In gathering olives for any purpose, they must be picked from the tree by hand and all bruising of the fruit avoided. Cloth bags or lined buckets hung over the shoulders of the pickers are used. Knocking the olives off the trees with rods and gathering from the ground is never practised for pickling olives; nor is it advisable for oil olives, as the mechanical injuries to the fruit promote rotting and molding which much depreciate the quality of the oil. Beating the trees also destroys much of the best fruit wood and tends to promote the spread of the olive-knot disease. Where oil olives can be marketed immediately, they may be gathered by means of special rakes with wooden teeth.

Pickling olives.

When pickles are made, the olives should be cleaned and sized as soon as possible after gathering. The sizing is done by mechanical graders which sort the olives into three or more sizes. The larger sizes are each pickled separately and the smallest used for oil. The grader should be such that the fruit is bruised as little as possible. The cleaning is accomplished by a blower which removes leaves and similar light materials and by running the olives into water which removes the dust.

The pickling process consists in removing the bitterness by means of soda or potash lye and water, then hardening and preserving the olives with a solution of common salt.

The nature of the lye treatment will depend on the variety, size and degree of ripeness of the fruit. For this reason, each variety and grade should be treated separately. The effect of the lye is partially to destroy the bitterness and to make the skin more pervious to the pickling solutions. Some varieties of olives are extremely bitter or thick-skinned and require two or three times as much lye as other varieties. If too little lye is used, the extraction of the bitterness will be very slow and often incomplete; if too much is used, the olives will become soft, the flavor will be injured and the nutritive value impaired by saponification of some of the oil.

2575. Ancient olive tree in orchard in south of France.

Average olives are placed in a solution composed of two ounces of potash lye to one gallon of water. They are left in this solution from four to not more than twelve hours. When the lye has penetrated nearly to the pit as shown by a darkening of the flesh, the olives should be removed to a bath of pure water. With very bitter olives, a second treatment with lye is often necessary. Stronger lye is likely to soften the fruit too much. With very ripe or soft olives, it is necessary to use salt from the beginning in the lye solution. Equal quantities of salt and lye may be used and more time is needed for neutralization owing to the hardening effect of the salt. Some picklers prefer to use a 1 per cent lye for all olives and to repeat the treatment two or three times. The next step is to remove the excess of lye from the olives. If the olives are firm, this is most economically and rapidly accomplished by soaking in pure water which is changed twice a day. If the olives are soft, the water should contain 2 per cent of salt. As soon as no taste of lye remains in the olives, they are placed in a brine composed of four ounces of salt to one gallon of water. This brine is replaced in about two, seven and twenty-one days with brines of six, ten and fourteen ounces to the gallon. This gradual increase of the strength is necessary to prevent shrinkage and shriveling of the olives.

Great care should be taken not to allow the olives to come in contact with anything that will injure their flavor. The vats or other receptacles used for pickling should be perfectly clean, odorless, and tasteless. Concrete is the best material, but wooden receptacles thoroughly treated with boiling water and soda until they are sterilized and all taste of the wood removed, may be used. The vats should be provided with a removable wooden grating, fastened 1 or 2 inches from the bottom, and a close-fitting, floating wooden cover to keep all olives submerged. Each vat should be provided at the bottom with a wooden spigot for drawing off the solutions. The thickness of the layer of olives should not be more than 2 feet. or less with soft varieties.

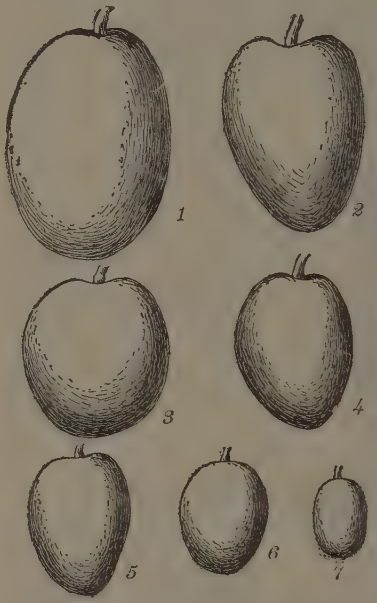
In pickling green olives, when a light color is desirable, the fruit should be exposed as little as possible to the air, especially during the extraction of the bitterness. In pickling ripe olives, on the contrary, when a uniform dark color is desired, the action of the air is beneficial. A great improvement in this respect can be obtained by leaving the olives exposed to the air for twenty-four hours when making the various changes of lye and salt solutions.

However carefully the processes of pickling are carried out, the olives will keep only for a limited time. They usually remain in good condition for about six months when kept in a strong brine, and the best may last in fair condition for a few months longer. Few olives are good when kept in the ordinary way for twelve months, but by heating them in sealed cans or bottles, they can be kept indefinitely with as great facility as any other food-product. The heating does not injure the flavor and the texture, but, on the contrary, improves them. Olives preserved by heating do not require such strong brine, and it is only necessary to add as much salt as the palate requires.

Olive oil.

The best oil is made by working the olives as soon as they are gathered, but it is usual to dry them partially first to facilitate crushing and pressing. The drying is accomplished by spreading the fruit in layers not over 3 inches deep on wooden trays which are spread out in a well-aërated shed or loft. The olives must be turned daily and prevented from molding. In cool, moist weather this is very difficult, and artificial driers constructed on the same principles as those for fruit and hops are sometimes used. The heat of these driers should be between 120° and 130° F. Higher temperatures produce rancidity of the oil. Artificial drying requires about forty-eight hours; natural drying one to two weeks. The dried olives may be stored in a cool, dark, dry place for some time before crushing, but the sooner they are used the better the oil, especially when dried by artificial heat.

The olives are first passed through a crusher consisting usually of corrugated rollers which disintegrate the flesh without breaking the pits. The crushed mass is then put under a press of moderate power. To facilitate the escape of the oil and water, the crushed olives are placed in layers of 3 to 4 inches, inclosed in strong cloth and separated by gratings. After this pressing, the pulp is thoroughly ground, usually with the pits, in an "edge-runner" mill. The ground pulp is then pressed a second time. The second pressing requires a very powerful press and very strong cloth to contain the pulp. The first pressing may be omitted when the olives are dried.



2576. Varieties of olive. ***1*, Ascolano; *2*, Sevillano; *3*, Manzanillo; *4*, Mission; *5*, Nevadillo; *6*, Frantoio; *7*, Redding.** (× about $\frac{5}{8}$).

The liquid which comes from the press contains oil, water and various impurities both solid and dissolved in the water. If allowed to stand, the oil, owing to its light specific gravity, will come to the top and may be skimmed off and freed from floating solid matters by screening. The separation, however, is very slow and imperfect and is facilitated by the process known as "washing." There are various devices for this purpose but they all consist in mixing the press liquids with a stream of pure water with continued gentle agitation. Some of the devices are continuous and the oil rising to the top flows off into the oil vats and the water and impurities escape at the bottom.

The oil thus obtained is more or less cloudy owing to the presence of minute particles of solid matter and must be made perfectly bright before it is merchantable. Perfect clarification of the oil may be accomplished by several successive settlings and decantations. The settling vats may be of tin or concrete. Drawing off after a settling of twenty-four to forty-eight hours removes most of the solid matter. The remainder is removed by two or three drawings-off, each after a settling of about a month. Filtration is usually used to hasten clarification. The most commonly used filtering materials are cotton, pure sand and filter paper. Filtering must be practised with moderation as it tends to diminish the flavor.

Only 50 per cent to 65 per cent of the oil is recovered by the methods now in use in California. The pulp with the retained oil is wasted or used as pig feed. A somewhat large percentage of the oil can be recovered by means of a centrifugal machine and the troublesome pressing and press cloths done away with. This method, however, has never been adapted to an industrial scale. Pressing is also done away with in the "Acapulco" method by which the oil is extracted by a partial vacuum. This method is said to be used successfully in several mills in Spain and Italy.

Varieties.

A very large number of olive varieties have been introduced into California, including the principal varieties of Spain, France and northern Italy. Many of these, especially the Italian varieties, are too small to make acceptable pickles and have been in great part abandoned or grafted over with larger varieties. Most of the recent plantings have consisted of Mission, Ascolano, Manzanillo and Sevillano, though about ten or twelve varieties are still found in commercial quantities. Short descriptions of the chief of these are given.

Mission (Fig. 2576).—The fruit of the common or broad-leaved Mission is typically olive-shaped, slightly oblique and pointed. Its deep color when ripe makes it suitable for ripe pickles. It ripens rather late and does not fruit nor mature well in the cooler sections. It varies in size from small to large according to soil, climate and cultural conditions. The ripe fruit is very bitter but it is firm and easy to pickle. It is one of the best oil olives among the large varieties, both as regards quantity and quality. More than half of the olives of California are of this variety.

Ascolano (Fig. 2576).—This variety, the largest of all the olives grown in California, comes from Italy, where it is grown in the province of Umbria. It is regularly ellipsoidal in shape and has a very small pit. It is sometimes called the "white olive of Ascoli" because it has very little color even when perfectly ripe. This is considered a defect for ripe pickles but by proper aëration during pickling, it can be made sufficiently dark and the color has the advantage of being very uniform. It maintains its size under most conditions and bears good crops in all the sections where it has been tried. It contains very little bitterness and requires very moderate lye treatment. Its flesh is somewhat tender and this and its large size make special care and skill necessary in preparing the ripe pickles. Many picklers have failed in this respect, but by the proper use of salt from the beginning and careful use of lye, success is not difficult and the pickles when well made command the highest price. Plantings of this variety have been heavy for several years and limited only by the scarcity of nursery trees.

Manzanillo, Number 1 (Fig. 2576).—This olive is of Spanish origin and, as its name indicates, it is apple-shaped. It is deeply colored and bitter when ripe and requires treatment with strong lye, but as it softens easily in pickling great care is needed. It ripens several weeks earlier than the Mission. It is on the average a little larger than the Mission though the largest samples of both varieties do not differ much. Its oil is somewhat inferior to that of Mission both in quantity and quality. *Manzanillo, Number 2* is the variety usually pickled in Spain. It is of excellent quality but too small for the Californian market.

Sevillano (Fig. 2576).—This is the variety from which the largest "Queen" olives of Spain are made. The largest specimens excel the Ascolano in size but it is less uniform. It is of typical olive-shape. It has a large pit and is deeply colored like the Mission. It is particularly suited for making both green and ripe pickles, but its large size makes special care necessary in the process. It is a good bearer in good, rich soil in warm localities but its range of adaptation seems more limited than that of the Ascolano.

Macrocarpa and *Polymorpha*, which seem to be synonyms, are very large and suitable for ripe pickles but are liable to a disease causing a spotting or softening of the flesh which much decreases their value.

Among other large-fruited varieties which have been tried and which have given good results in some sections are Obliza, Salonica, Regalis, Empeltre, and Columbella. These are not being largely planted now, as they are excelled in most respects by the four preferred varieties.

Among smaller varieties which under favorable conditions produce fruit large enough for pickling are the Nevadillo blanco, Oblonga, Pendulina and Uvaria. The Nevadillo (Fig. 2576) especially was planted largely at one time and under suitable conditions is one of the best oil olives. It is, however, sensitive to cold, subject to dry-rot of the fruit and in many sections an unreliable bearer. The Picholine, a variety used in France for "olives farcies" gives excellent fruit in California but has been little planted. The so-called Redding Picholine (Fig. 2576), which was largely planted some years ago under the impression that it was the true French Picholine, is a seedling whose fruit is very small and useless. Frantoio (Fig. 2576) is a type of Italian oil olive which does well in California, but is not profitable, as the fruit is too small for pickling.

FREDERIC T. BIOLETTI.

OLIVE-BARK TREE: *Terminalia Catappa.*

OLIVERÁNTHUS (*Oliver's flower;* named in compliment to G. W. Oliver, U. S. Dept. Agric.). *Crassulàceæ.* A genus of 1 species, Mexican, separated from Cotyledon (or Echeveria), the fls. not strongly 5-angled, very large and solitary, at the ends of slender branches. **O. élegans,** Rose (*Cotylèdon élegans,* N. E. Br. *Oliverélla élegans,* Rose), is a caulescent and much-branched perennial, 12–20 in. high, with flat fleshy oblanceolate to spatulate lvs. closely placed near the ends of the branches: corolla about 1 in. long, bright red with yellow tips, elongated and the lobes nearly free to the base: carpels 5, free. B.M. 7993. G.C. III. 44:275.—An attractive summer-blooming plant, with large fls. of good substance borne on rather slender branches. It does very well out-of-doors at Washington, in sandy soil.

L. H. B.

OLNÈYA (Stephen T. Olney, American botanist and specialist in Carex). *Leguminòsæ.* One species, *O. Tesòta,* Gray, a small tree (15–20 ft. and more) in S. Calif., Ariz., and Mex., known locally as ironwood: often spiny: lvs. equally or unequally pinnate, the lfts. thick and entire, the stipules none: fls. white or purplish, in short axillary racemes; petals free and equal; stamens 10, diadelphous: pod 1–2-seeded, thick, with coriaceous valves, linear-oblong, 1–2 in. long, hairy. Probably not regularly in cult.

OMALÁNTHUS: *Homalanthus.*

OMPHÀLEA (Greek for *naval* or *center,* from the form of the disk or anthers). *Euphorbiàceæ.* Mostly climbing or twining shrubs of the tropics. Juice milky: lvs. alternate, entire, pinnately veined: fls. in terminal panicles, small, apetalous, monœcious; staminate calyx with 4–5 broad, free, imbricate sepals; stamens 2–3, filaments connate; ovary 3-celled, 1 ovule in each cell: fr. large, fleshy outside.—Twelve species in Trop. Amer. and 3 in the Old World tropics. Related to Sapium and Stillingia. Cult. in rich light soil; prop. by cuttings rooted with heat. *O. triándra*, Linn., Cob-Nut, Pop-Nut, Pig-Nut, with oblong obtuse lvs. and yellow fr. 1½ in. thick, has been cult. in Eu. The blackening juice of the fr. has been used in ink and the nuts eaten after removal of the poisonous embryo. W. Indies. L.B.C. 6:519. *O. megacárpa*, Hemsl., with lanceolate, acute lvs., is native and cult. in the W. Indies, the large seeds, Hunter's-Nut, being eaten as a nutrient and stimulant. H.I. 2537. *O. diándra*, Linn., with broad ovate or oblong lvs., or a related species, has been intro. from the mountains of Colombia, where the oily seed is eaten and fed to hogs. J. B. S. Norton.

OMPHALÒDES (Greek, *navel-shaped;* referring to the seeds). *Boraginàceæ.* Navelwort. Flower-garden and border plants, something like forget-me-not, not often seen in American gardens.

Annual or perennial herbs of low growth, glabrous or sparsely and minutely villous: root-lvs. long-stalked, lanceolate, ovate or cordate; st.-lvs. few, alternate: racemes lax, with or without a leafy bract at the base; calyx 5-parted; corolla-tube very short; lobes 5, imbricated, broad, obtuse; stamens 5, affixed to the tube, included; ovary 4-lobed. From Myosotis it differs in having depressed nutlets and nearly horizontal seeds, while in the forget-me-not genus the nutlets are ovoid, and the seeds erect. Since the cult. material is doubtful, the descriptions given below are adapted mostly from DeCandolle's Prodromus, vol. 10 (1846), with which the pictures cited agree rather poorly. The genus here characterized has the limits understood by Bentham & Hooker, and by Gray.—About two dozen species, native to the Medit. region, Cent. Asia, and Japan; also in Mex. and sparingly in W. U. S. (the latter by some referred to Eritrichium). For *O. longiflora*, see *Lindelophia.* The group to which Omphalodes belongs is variously understood by botanists.

Of this genus a few low-growing hardy herbs are cultivated, with flowers much like those of forget-me-not, but larger and usually with a white five-pointed star dividing the corolla-lobes. The flowers are often more or less pinkish, particularly toward the center. They like moist situations, but in deep shade grow too luxuriantly; also the flowers are fewer and of a weaker blue. Partial shade or full sunlight is preferable. The commonest kind is the "creeping forget-me-not," *O. verna,* which is a spring-blooming perennial of easy culture, producing runners freely and easily propagated by division. It can be grown by the yard in a rockery and can be easily naturalized in wild moist half-shaded spots. It is also good for fringing walks. It is said to like best a cool, moist loam, with a few bits of sandstone among which the roots may ramble and from which they may derive coolness and moisture. Perhaps the choicest kind is *O. Luciliæ,* also a spring-blooming perennial, but of tufted habit and impatient of division. It is a native of Asia Minor at a height of 8,000 feet, and grows in fissures of vertical cliffs. It is said to like a loose limestone soil, deep and well drained. When once established it self-sows. *O. linifolia* is a summer-blooming annual of easy culture. *O. verna* has a white-flowered kind, which is pretty but to most persons lacks the interest of a blue-flowered forget-me-not.

A. *Plant a summer-blooming annual.*

linifòlia, Mœnch. Erect, slightly glaucous, 1 ft. high: radical lvs. wedge-shaped; st.-lvs. linear-lanceolate, margin remotely ciliate: corolla twice as long as the calyx: nutlets dentate, inflexed at the margin. Dry, stony hills of Spain and Portugal. June–Sept. According to DeCandolle, the fls. are normally white, and it is var. **cærulèscens,** DC., which has bluish fls., sometimes tinged with rose. This interesting species belongs to a group of Omphalodes in which the nutlets are affixed laterally and lengthwise to the style which is pyramidal and has a square base.

AA. *Plants perennials, mostly spring-blooming.*

vérna, Moench. Creeping Forget-Me-Not. Stoloniferous perennial: flowering-st. erect: lvs. sparsely puberulous; radical ones long-petioled, ovate or subcordate; st.-lvs. short-petioled, sublanceolate; all lvs. acuminate, callous at the apex: fls. borne in pairs in a raceme. April, May. Eu. B.M. 7 (as *Cynoglossum Omphalodes*). Gn. 26, p. 315; 40:150; 72, p. 240.—Fls. light blue, according to DeCandolle. Var. **álba,** Hort., is also offered.

Lucíliæ, Boiss. Glabrous, tufted perennial: lvs. oblong, obtuse, the radical lvs. narrowed into a long petiole, the st.-lvs. sessile, upper ones ovate: pedicels longer than the nearest floral lf., erect, then arcuate-recurved: fls. blue; calyx-lobes ovate-oblong, somewhat obtuse, about one-fourth as long as the pedicels; corolla broadly funnel-shaped, about four times as long as the calyx: nutlets with an entire membranaceous margin. Mt. Sypilus near Manesis, and in Cilicia near Gulf of Scanderoon, at 8,000 ft. B.M. 6047 (some fls. light blue, others pinkish purple, all with a white eye). Gn. 27: 194; 69 p. 283. G.C. III. 40:53. G. 28:413.—Fls. about ½in. across, twice as large as those of *O. verna.*

cornifòlia, Lehm. (*O. cappadòcica,* DC.). Perennial herb, 6–8 in. high, sometimes grown as an alpine, with variable but usually cordate-lanceolate lvs. which are silky-hairy and with prominent arching veins: fls. about ½in. across, clear rich blue with small white eye, in loose erect cymes. Asia Minor. G.C. III. 53:380.

nítida, Hoffm. & Link. Perennial, with erect branching glabrous sts.: lvs. oblong-lanceolate, glabrous and shining above, pubescent beneath, the lower ones long-petioled and the upper ones sessile: fls. sky-blue with white center, in very long bractless racemes, the pedicels and calyx pilose. Portugal.—Said to be a plant of neat habit for half-shady moist places.

O. florariénsis, Corr., is a garden hybrid between O. Luciliæ and O. nitida (H. Correvon, Floraire, Geneva, Switzerland).

Wilhelm Miller.
L. H. B.†

ONCIDIÒDA (compounded from *Oncidium* and *Cochlioda*). *Orchidàceæ.* A genus established to contain the hybrids between Oncidium and Cochlioda.

O. Chárlesworthii (O. incurvum × C. Noetzliana) has the infl. of the former, the fls. scarlet and lavender. F.E. 33:499.—*O. cinnabarìna*=O. monachicum × C. Noetzliana.—*O. Coòksoniæ*=O. macranthum × C. Noetzliana.—*O. Mauricii*=O. tigrinum × C. vulcanica. G.C. III. 55:326. George V. Nash.

ONCÍDIUM (Greek, *a tubercle;* alluding to the crest on the labellum). *Orchidàceæ.* Epiphytal orchids for greenhouse growing.

Pseudobulbs usually present, wanting in a few species, 1–2-lvd., with sheathing lvs. at the base: lvs. plane, terete or triangular: petals like the dorsal sepal but often much larger; lateral sepals either free or partially united; labellum variable, but never with its base parallel to the column (Odontoglossum), spreading nearly at right angles to the column; column short, winged.—A broad genus with over 300 species distributed in Mex., Cent. and Trop. Amer., and in the W. Indies. In range of altitude the genus extends from the hot coast regions to elevations of 12,000 ft. in the Andes. The fls. of this genus show a remarkable diversity of form. In *O. varicosum, O. tigrinum* and related species, the labellum is greatly developed, forming the most conspicuous part of the fl., while in *O. serratum* and *O. macranthum* it is inconspicuous. The sepals and petals vary in size in relation to each other and to the rest of the fl. A remarkable example is *O. Papilio,* in which the petals and dorsal sepal have been transformed into linear-erect segms., recalling, on a large scale, the antennæ of some insect. The general habit of the plants is no less variable than the fls. They range in size from small erect forms, scarcely 6 in. in height (*O. pumilum*), to those resembling *O. altissimum*, with immense climbing panicles 9–12 ft. high and covered with numerous medium-sized fls. The prevailing color of the fls. is yellow, spotted and barred with brown. White or rose-colored fls. occur in a few rare examples (*O. incurvum, O. ornithorhynchum*).

As a class, oncidiums are short-lived under cultivation. Few growers succeed in maintaining them in good condition for any great length of time. The stock is constantly renewed from the tropics.

Cultivation of oncidiums.

The genus Oncidium embraces a great number of species which are found growing under such peculiar and varied conditions in their native homes that imitation of the same is usually impracticable and often quite impossible. A fair degree of success, however, may be obtained by careful observation and distribution of the exceptionally difficult species among the several orchid departments.

The Sarcoptera section, which embraces such species as *O. Cavendishianum, O. Lanceanum, O. luridum, O. pulvinatum* and others of similar structure, and the *O. Papilio* section, with *O. ampliatum*, may be successfully grown in a bright warm portion of the cattleya department in small baskets suspended from the roof, using for a compost a mixture of clean chopped peat and sphagnum moss, freely interspersed with lumps of broken charcoal. *O. cucullatum, O. incurvum, O. macranthum, O. ornithorhynchum, O. Phalænopsis, O. varicosum*, with a few others of like nature, do well under treatment similar to that given for odontoglossums, which see.

When a good collection of species is cultivated, a large number, including many of the above, can be readily grown in one house if it be especially adapted to them. Such a house should be a span-roof structure of east and west exposure, at an angle of about 40°, which will admit the longest possible light. The early morning and late afternoon sun striking the glass at right angles produces and prolongs the natural sun heat for a greater part of the day, while at midday, when the outside temperature is highest, the sun's rays strike the glass obliquely, giving less heat, with little danger of the plants becoming sunburned from lenses in the glass. Oncidiums require more sun and air than most orchids.

The benches may be of either wood or stone, and should be covered an inch or two in depth with sand, ashes or gravel. The benches and paths should be wet down once or twice daily to insure a moist atmosphere. Ventilators should be arranged on both sides of the roof: air may then be freely admitted without causing direct drafts on the plants by using the ventilators on the sheltered side. In winter the temperature should range from 50° to 55° F. at night and 60° to 65° by day, or a few degrees more with sun heat and ventilation. In summer it must be kept as low as outside conditions will permit. From March until October, shading must be applied to the glass sufficiently heavy to keep down the temperature without excluding indirect solar influence. A good shading is made of turpentine and white lead; it stands well and is easily removed. It can be applied rapidly with a whitewash brush on a long pole, and removed with a hard brush in the fall.

Oncidiums may be grown in either pots or baskets, but as many species are of rambling habit, the latter are preferable. The tiny species, such as *O. Limminghii*, do best on blocks with little compost beneath them. Clean chopped peat fiber and live sphagnum moss, equal parts, make the best general growing material, and this should be liberally interspersed with broken pieces of charcoal. The plants in all cases must be securely fastened, and the compost must be pressed in moderately firm, but should be used sparingly. Overhead syringing should be given frequently, about once or twice a day in bright weather, but care must be taken not to keep the compost too wet, for the roots are liable to decay: it is advisable to let them dry out occasionally.

Stock is increased by division or notching the rhizome between the pseudobulbs just before the growing season, allowing about three or four pseudobulbs to each piece and separating the parts after the first growth is matured.

For other cultural notes on the genus, see the various manuals on orchid-growing.

SYNOPSIS OF SECTIONS.

A. *Lvs. plane, not terete.*
  B. *Labellum smaller than the sepals and petals*... Species 1–5
  BB. *Labellum at least as large as the other segms., often greatly exceeding them.*
    C. *Lateral sepals more or less united at base.* Species 6–18
    CC. *Lateral sepals free.*
      D. *All the segms. having a distinct blade, none of them linear-subterete.*
        E. *Pseudobulbs present*.........Species 19–37
        EE. *Pseudobulbs wanting or obsolete* Species 38–44
      DD. *Only lateral sepals with distinct blade; dorsal sepal and petals elongate, linear, erect, with an obsolete blade*.....Species 45–46
AA. *Lvs. terete or subterete*...............Species 47–48
AAA. *Lvs. subtriangular in section*..........Species 49

DESCRIPTION OF SPECIES.

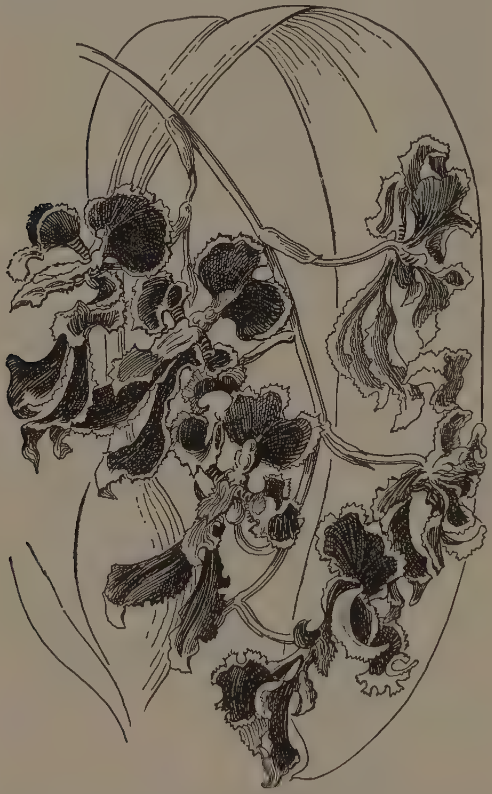
A. *Lateral sepals united at base*......... 1. **micropogon**
AA. *Lateral sepals free.*
  B. *Sepals and petals linear, flaccid*.... 2. **phymatochilum**
  BB. *Sepals and petals broad, serrate*.... 3. **serratum**
  BBB. *Sepals and petals broad, entire or subentire.*
    C. *Fls. brown*.................... 4. **superbiens**
    CC. *Fls. yellow*.................... 5. **macranthum**

1. **micropògon**, Reichb. f. Pseudobulbs almost in 2 rows on the rhizome, broadly ovoid: lvs. 4–6 in. long, linear-oblong, rounded at the top, leathery: raceme 8–10 in. long, on a long stalk, flexuous, pendulous; fls. 1½ in. across; sepals linear-oblong, undulate, yellow, barred with brown; petals clawed, orbicular, yellow, with a deep red-brown claw; labellum yellow, smaller than the petals, having 3 almost equal, rounded, clawed lobes. Aug. Trop. Amer. B.M. 6971. Gt. 4:308. Var. **supérbum**, Hort., is advertised.

2. **phymatochilum**, Lindl. Pseudobulbs broadly fusiform, 4–5 in. long, purplish brown, with several large

scales at the base: lvs. membranous, oblanceolate, 12–14 in. long: scape rather slender, over 1 ft. long, with a pendent panicle more than a foot long: sepals and petals linear-subulate, flaccid and somewhat twisted, greenish yellow, with deep orange blotches; labellum shorter than the sepals, white, with a yellow and orange crest; the middle lobe triangular-ovate, acuminate. Brazil. B.M. 5214. F.S. 23:2465. G.C. 1848:139.

3. **serràtum,** Lindl. Fig. 2577. Pseudobulbs 4–6 in. long, partly inclosed by sheathing lvs., 1–2-lvd.: lvs. about 1 ft. long and 2 in. broad: infl. a long, twining, loosely-branched panicle, 6–10 ft. long; fls. numerous, 3 in. across; upper sepals broad, reniform, the lateral ones very much longer, obovate, all chocolate-brown, with yellow tips and margins, strongly undulate, serrate; petals shorter, oblong, wavy and curled so that they almost meet over the column, yellow with brown spots, margins serrate; labellum small, hastate, fleshy, with a crest of 5 ridges. Winter. Peru. B.M. 5632. F.S. 6, p. 167.



2577. **Oncidium serratum.** (×½)

4. **supérbiens,** Reichb. f. Pseudobulbs 3–4 in. long, ovate to ovate-lanceolate, much flattened: lvs. linear, 14 in. long and 1¼–1½ in. broad, some sheathing the pseudobulb: panicle 2–3 ft. long, loosely branched and flexuous, bearing 20–30 fls. each 2½ in. diam.; sepals long-clawed, undulate, chocolate-brown with yellow tips; the upper one trowel-shaped, with a cordate base, the lower pair more ovate; petals rather smaller, with shorter, broader claws, much recurved and wavy, yellow with brown bars; labellum less than half as large as the sepals, revolute, trowel-shaped, with auriculate side lobes, brown with a yellow crest. Spring. Venezuela, Colombia. B.M. 5980.

5. **macránthum,** Lindl. (*O. hastiferum,* Hort.). Pseudobulbs ovoid or flask-shaped, 3 in. long: lvs. narrowly lanceolate, acuminate, 1 ft. long: panicle climbing, loosely branched and many-fld.; fls. 3–4 in. across; sepals rounded-oblong, with green claws, the upper one yellowish brown, the lower pair orange-yellow; petals similar, golden yellow, streaked with blood-red at the base; labellum small, hastate, purple-brown, with a prominent white crest. Spring and summer. Cent. Amer. B.M. 5743. Gn. 24:486. F. 1871, p. 187. J.H. III. 34:337.—A magnificent orchid, of which there are several varieties, some of secondary merit.

A. *Petals clawed, with a broad, obovate or rounded blade, not much smaller than the labellum.*
B. *Fls. yellow; column-wings short, quadrate*.................... 6. **Marshallianum**
BB. *Fls. red-brown; column-wings narrow, angular*.................. 7. **Forbesii**
BBB. *Fls. dull brown, with yellow markings.*
C. *Column-wings small, truncate*.... 8. **curtum**
CC. *Column-wings large, sharply serrate*.......................... 9. **crispum**
AA. *Petals and dorsal sepals obovate, cucullate, not clawed*..............10. **cornigerum**
AAA. *Petals and dorsal sepals subsimilar, very small; labellum larger than the rest of the fl.*
B. *Labellum white, spotted with rose-purple*.........................11. **cucullatum**
BB. *Labellum yellow.*
C. *Blade bifid*....................12. **Martianum**
13. **flexuosum**
CC. *Blade quadrifid*................14. **varicosum**
AAAA. *Petals and sepals lanceolate, ovate, at least one-half as long as the labellum and of a different form.*
B. *Fls. white, spotted with purple*......15. **Phalænopsis**
BB. *Fls. yellow or greenish, spotted and barred with brown.*
C. *Crest serrate*..................16. **longipes**
CC. *Crest a smooth, heart-shaped callus*........................17. **dasystyle**
BBB. *Fls. entirely yellow*..............18. **concolor**

6. **Marshalliànum,** Reichb. f. Pseudobulbs ovoid, 2–4 in. long: lvs. narrowly oblong, 6–8 in. long: fls. numerous, 2½ in. across, borne on a stout panicle 1–2 ft. high; the upper sepals oblong-apiculate, the lateral ones united, yellow, with purplish bands; petals much larger, fiddle-shaped, wavy and 2-lobed, golden yellow, with few blotches of chocolate-brown; labellum with a very large spreading 2-lobed middle lobe and ear-like side lobes, yellow, with orange-red spots on the base. May. Brazil. B.M. 5725. F.M. 1877:285.—A very effective and showy plant related to *O. crispum.* Var. **sulphùreum,** Hort., has yellow fls. without the usual markings.

7. **Fórbesii,** Hook. Pseudobulbs rather small, oblong, compressed and sulcate: lvs. lanceolate, dark green, 9 in. long: panicle about 1 ft. high, bearing numerous handsome fls. 2 in. across; fls. rich reddish brown, margined with yellow; sepals small, obovate; petals twice as large, obovate-rotund; side lobes of the labellum small; middle lobe spreading, fan-shaped. Autumn. Brazil. B.M. 3705. G.C. II. 11:525.—A rare but very ornamental orchid. Var. **atràtum,** Hort., has large fls., purple-brown. Var. **Brádshawæ,** Hort., an alpine form with yellow markings.

8. **cúrtum,** Lindl. Lvs. and pseudobulbs like those of *O. crispum:* infl. an erect, much-branched pyramidal panicle; fls. 1–1½ in. across; lateral sepals united, rather small; dorsal sepals and petals obovate-obtuse, yellow, with reddish brown bars and blotches; labellum with small lateral lobes and a roundish, notched middle lobe, yellow bordered with brown; crest lobed and warted, yellow, with red spots. Brazil. B.R. 33:68. Gn. 10, p. 131; 31, p. 198; 34, p. 87.—Blossoms in spring, the fls. remaining fresh for several weeks.

9. **críspum,** Lodd. Pseudobulbs oblong, sulcate, rough and usually dark brown: lvs. leathery, lanceolate,

about 9 in. long: fl.-st. 1–1½ ft. high, arched, bearing 20–50 large fls. 1½–3 in. across: fls. shining brown, with few yellow and red marks at the bases of the segms.; sepals obovate, obtuse, recurved and undulate, the lateral ones united; petals twice as large, broadly obovate, obtuse, much waved and crisped; middle lobe of the labellum large, rotund-cordate, waved and crisped; lateral lobes small, horn-like. Fls. at various seasons. Brazil. B.M. 3499. B.R. 1920. L.B.C. 19:1854. F.S. 21:2147, 2148. F.C. 2:64. B. 1:26. O. 1912, p. 18; 1913, p. 74. Var. **grandiflòrum,** Hort. Fls. very large, the segms. edged with yellow.

10. **cornígerum,** Lindl. Pseudobulbs oblong, sulcate, 3 in. long, 1-lvd.: lvs. dark green, broadly ovate to oblong, fleshy, ribbed, 4 in. long: panicle about 18 in. long, drooping, branched and crowded with fls. above; fls. small but numerous, yellow, spotted with red; dorsal sepals and petals obovate, concave, undulate, the lateral sepals smaller and united; labellum with long-linear lateral lobes and 2 horn-like processes at the base; middle lobe obovate, subrepand. April, May. Brazil. B.M. 3486. B.R. 1542.—A compact free-flowering plant which is very attractive when grown in baskets so that the long racemes can hang over the sides.

11. **cucullàtum,** Lindl. Pseudobulbs oval, 1½ in. long, smooth, becoming ribbed: lvs. oblong-lanceolate, 6 in. long: raceme almost simple, 8–12 in. long, bearing 6–12 fls. 1¼ in. across; dorsal sepals and petals small, oval, greenish, shaded with rose-purple; lateral sepals almost entirely united; labellum cordate-panduriform, with the middle lobe much dilated and 2-lobed, white to rose and spotted with dark purple. Spring. Colombia. F.S. 8:835; 23:2457. J.F. 3:317. J.H. III. 49:365. I.H. 25:305. Gn. 22:166 (var. *giganteum*).—A species with many varieties, which differ in shape and coloring of the fls. It is one of the coolest of the Andean orchids. Var. **nubígenum,** Lindl. Raceme suberect; sepals and petals white or light purple, with green tips; labellum white, with a purple blotch around the crest. B.M. 5708.

12. **Martiànum,** Lindl. (*O. bícolor,* Lindl.). Pseudobulbs ovate, compressed and ribbed: lvs. oblong, striate: fls. yellow, spotted; lateral sepals united, ovate, acute; petals obovate, concave; middle lobe of the labellum larger than the rest of the fl., 2-parted by the deep sinus in front, clear yellow. Autumn. Brazil. B.R. 29:66.—A beautiful yellow species, with a panicle 2 ft. high.

13. **flexuòsum,** Sims. Pseudobulbs ovate, flattened, 2 in. long: lvs. linear-oblong, 6 in. long: fls. scarcely 1 in. across; sepals and petals small, recurved, yellow, with chestnut bars; labellum yellow, with few reddish spots; side lobes small; middle lobe reniform, notched. Brazil. B.M. 2203. L.B.C. 5:424. Gn.W. 7:53.—The plant blooms freely at various seasons. The fls. open in succession on a loose spreading panicle about 2 ft. high. Var. **unícolor,** Hort., has clear unspotted fls.

14. **varicòsum,** Lindl. Pseudobulbs ovate, angled, 2–4 in. long: lvs. rigid, linear-lanceolate, 9 in. long: fl.-spikes strong, arching, 3 ft. long, with numerous fls. 1 in. across; sepals and petals small, green, with brownish blotches; labellum very large in proportion to the fl., bright yellow, with a curiously toothed crest; lateral lobes rotund; middle lobe reniform, obscurely 4-lobed. Winter and spring. Brazil.—One of the most attractive. J.F. 2:206, 207. J.H. III. 54:497; 69:355. Var. **Rógersii,** Reichb. f. (*O. Ródgersii,* Hort.). Fig. 2578. The best variety. Specimens have borne 150 fls., with the lip over 2 in. across, rich yellow, with a few red bars at base. G.C. 1870:277. F.S. 18, p. 150. F. 1870:25. Gn. 55:408. G.M. 39:366. A.F. 17:10. Gng. 10:38. J.H. III. 49:433. O. 1912, p. 18. Var. **Chárlesworthii,** Hort.. Lip 2¾ in. across. G.M. 45:566. Var. **moortebeekiénse,** Hort. A large reddish brown blotch at base of lip. G.M. 45:177.

15. **Phalænópsis,** Lind. & Reichb. f. A small-growing plant, with pseudobulbs oblong, somewhat ribbed, 1–2 in. high: lvs. narrow at the base, broadening upward, about 6 in. long: fls. 3–6 on a slender raceme, gaily colored, creamy white, with the sepals and petals barred with reddish purple, and the base of the lip profusely spotted with the same color; sepals and petals quite similar, oblong, acute; labellum pandurate, with 2 rounded lobes in front. Blooms at various seasons, and lasts a long time. Ecuador. I.H. 17:3. Gn. 41:492. J.H. III. 28:515.—A beautiful little plant, worthy of extended cult. Much like *O. cucullatum.*

16. **lóngipes,** Lindl. (*O. janeirénse,* Reichb. f.). Pseudobulbs narrowly ovate, 2-lvd.: lvs. narrow: scape several-fld., equaling the lvs.; fls. on long pedicels; lateral sepals elongate, pendulous, united at the base; dorsal sepals shorter and wider, recurved; petals oblong, plane; all yellowish green, barred with brown; labellum yellow, spotted with brown at the base; lateral lobes small, obtuse; middle lobe transversely broadened, apiculate, the narrow part serrated. Summer. Brazil. I.H. 2:54. B.M. 5193 (called *O. longipes,* is *O. Crœsus,* Reichb. f.).—A small species.

2578. Oncidium varicosum var. Rogersii. (×⅓)

17. **dasýstyle,** Reichb. f. Pseudobulbs ovate, flattened, strongly rugose: lvs. 4–5 in. long, linear-lanceolate: scape very slender, 6–7 in. long, bearing 2–5 fls., each 1½ in. across; dorsal sepals and petals subequal, lanceolate, pale yellow, blotched with purple-brown; lateral sepals larger, united half-way; labellum large, sulfur-yellow, with a blackish purple callus; lateral lobes small, triangular; middle lobe round-fan-shaped, membranous and undulate. Jan., Feb. Organ Mts., Brazil. B.M. 6494.

18. **cóncolor,** Hook. (*O. unguiculàtum,* Klotzsch). Pseudobulbs small, oval-oblong, slightly furrowed: lvs. lanceolate: fls. 1–2 in. diam., rich yellow, borne on pendulous racemes 1–2 ft. long; lateral lobes united for half their length, smaller than the dorsal sepals and petals, which are obovate; labellum twice as long as

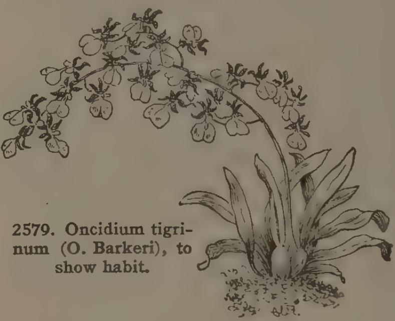
the sepals, broad, flat, bilobed, with 2 reddish ridges running down on the base. April–June. Organ Mts. B.M. 3752. I.H. 30:487. R.H. 1881:30. Gn. 13:58. G. 26:237; 27:133; 35:301.—A plant of close and compact habit, making one of the most attractive yellow coolhouse orchids. Var. **rhodóptera,** Hort. Upper part of column-wings and margin of stigma red.

A. *Labellum with a large reniform mid-lobe; lateral lobes small or none.*
  B. *Petals much broader than the sepals* 19. **ampliatum**
    20. **excavatum**
  BB. *Petals and sepals nearly of the same size.*
    C. *Fls. over 2 in. across; labellum large, forming the most conspicuous part of the fl.; panicle stout*......................21. **tigrinum**
      22. **splendidum**
    CC. *Fls. medium-sized, numerous, in long, climbing panicles.*
      D. *Sepals and petals linear-lanceolate, acute.*
        E. *Color of fls. white and purple.*23. **incurvum**
        EE. *Color of fls. yellow and brown.*
          F. *Column-wings very truncate; crest of several interrupted ridges*.......24. **Baueri**
          FF. *Column-wings rounded, slightly crenulate*......25. **altissimum**
          FFF. *Column-wings erose, sphacelate*............26. **sphacelatum**
          FFFF. *Column-wings falcate, dentate*..................27. **reflexum**
      DD. *Sepals lanceolate; petals spatulate*......................28. **Batemannianum**
      DDD. *Sepals and petals linear to oblong, obtuse.*
        E. *Color of labellum yellow*....29. **Harrisonianum**
        EE. *Color of labellum white*.....30. **leucochilum**
AA. *Labellum with the middle lobe variously shaped, rarely reniform, but more so than the lateral lobes, large.*
  B. *Fls. rose-colored*.................31. **ornithorhynchum**
  BB. *Fls. yellow, variously marked and spotted.*
    C. *Crest pulvinate, pubescent*.......32. **divaricatum**
      33. **pulvinatum**
    CC. *Crest not pulvinate.*
      D. *Apex of labellum deeply 2-lobed*.....................34. **Warneri**
      DD. *Apex of labellum apiculate, lateral lobes tooth-like*.......35. **maculatum**
      DDD. *Apex of labellum merely emarginate, lateral lobes large.*
        E. *Middle lobe broadly reniform, clawed*............36. **Limminghii**
        EE. *Middle lobe not clawed, separated from the lateral lobes merely by a sharp constriction*...................37. **cheirophorum**

19. **ampliàtum,** Lindl. Pseudobulbs subrotund, compressed, bright green with purple spots, becoming blackish purple and wrinkled with age: lvs. plane, oblong-lanceolate, 9 in. long: infl. a large panicle 1–3 ft. long, with numerous fls., which are yellow, spotted with red at the bases of the segms.; sepals and petals small, the former entirely free; labellum reniform, spreading, wavy, 1½ in. across, narrow at the base, with 2 small lateral lobes and a prominent lobed crest. March–May. Throughout the coast of Nicaragua. B.R. 1699.—The fls. are produced in magnificent panicles. In var. **màjus,** Hort., they are half again as large as in the type. F.S. 20:2140, 2141. G.C. III. 17:173. Gn. 45, p. 491. G.M. 27:475. C.L.A. 6:166. G. 17:202. J.H. III. 54:295.

20. **excavàtum,** Lindl. (*O. auròsum,* Reichb. f. & Warscz.). Pseudobulbs oblong, compressed, 3–5 in. long: lvs. 1½ ft. long, leathery, shining green: panicle 3–5 ft. long, with numerous fls. 1½ in. across, yellow, spotted with brown; sepals obovate, obtuse, free; petals oblong, retuse; labellum sessile, with several broken ridges near the base, pandurate, excavated on the under side; middle lobe rotund, emarginate. Autumn. Peru. B.M. 5293. I.H. 17:34.—Strong plants produce as many as 100 fls. on each panicle.

21. **tigrìnum,** LaLlave & Lex. (*O. Bárkeri,* Lindl. *O. unguiculàtum,* Lindl.). Fig. 2579. Pseudobulbs oval, compressed, 2-lvd.: lvs. oblong-lanceolate, thick, 1 ft. long: panicle erect, stout, 3 ft. high; fls. 2½ in. across; sepals and petals similar, lanceolate, undulate, rich reddish brown, with few bars and spots of yellow; labellum yellow, with a very large, orbicular-reniform blade supported on a long claw, lateral lobes oblong. Winter. Mex. I.H. 1:2; 22:221. P.M. 14:97. R.H. 1889, p. 176.—Very much like *O. splendidum,* from which it differs by the longer claw of the labellum having a thick keel, and the oblong lateral lobes of the labellum. Both are among the most showy oncidiums in cult. Var. **grandiflòrum,** Hort., is advertised. Var. **Crŏckii,** Hort. Sepals and petals marked with light brown bands.



2579. Oncidium tigrinum (O. Barkeri), to show habit.

22. **spléndidum,** A. Rich. Pseudobulbs small, round, compressed, 1-lvd.: lvs. leathery, oblong-ovate, 6–12 in. long: fl.-stalk erect, 2 ft. long; fls. 3 in. across; sepals and petals similar, lance-oblong, acute, recurved, yellow-green, with broad brown bands; labellum very large, yellow, the broad claw of the middle lobe expanding into a large reniform blade; lateral lobes small, rotund. Spring. Guatemala and Mex. B.M. 5878 (as *O. tigrinum* var. *splendidum*). F.S. 18:1825. Gn. 51:410. R.B. 17:108. G.C. 1871:42; III. 3:108.

23. **incúrvum,** Barker. Pseudobulbs ovate, compressed and ribbed, 2 in. long: lvs. 9 in. long, ensiform, acute: panicle 2–3 ft. long, slender, much branched and gracefully arched; fls. 1½ in. across, numerous; sepals and petals linear-lanceolate, undulate, white, banded with purple; labellum white, with a purple blotch; lateral lobes rotund, small; middle lobe subreniform, concave. Bears numerous panicles in autumn. Mex. B.M. 4824. B.R. 31:64. I.H. 2:49; 29:444 (white variety).

24. **Baùeri,** Lindl. (*O. altíssimum,* Lindl.). Pseudobulbs oblong, compressed: lvs. ensiform, rigid, keeled: panicle with numerous branches and rather dingy fls.; sepals and petals about as long as the labellum, linear-lanceolate, undulate, yellow, with red spots; labellum with 2 spreading lateral lobes and a reniform emarginate midlobe, yellow, with a reddish band. Trop. Amer. B.R. 1651 (as *O. altissimum*).—A gigantic epiphyte with fl.-sts. 6–9 ft. long and "lvs. as long." It has been confused with *O. altissimum.*

25. **altíssimum,** Swartz. Pseudobulbs nearly rotund, much compressed and edged: lvs. 1–2 at the top and several at the base of the pseudobulb, ensiform, keeled, 1½–2 ft. long: infl., an almost simple, drooping raceme, 4–6 ft. long; sepals and petals free, similar, spreading, linear-lanceolate, undulate, pale yellow, with olive-brown blotches; labellum nearly as long as the petals, fiddle-shaped, with the middle lobe reniform, spreading, yellow, with a brown band near the center, prominently crested. Aug. W. Indies. B.M. 2990. B.R. 1851.

26. **sphacelàtum,** Lindl. Pseudobulbs elongate-ovate, compressed: lvs. long, ensiform, apex recurved: scape

strict, bearing a many-fld. panicle; sepals and petals linear-lanceolate, undulate, yellow, spotted with brown; labellum about as long as the sepals; lateral lobes auriculate; middle lobe with 2 rotund lobes, yellow, with brown spots at the base. Spring. Honduras and W. Indies. B.R. 28:30. Var. **grandiflòrum,** Hort., is a better variety.

27. **refléxum,** Lindl. Pseudobulbs ovate, 1-lvd.: lvs. narrowly lanceolate, acute: panicle with its stalk 3–4 ft. long, pendulous; sepals and petals linear-lanceolate, undulate and reflexed, yellowish, shaded with pale brown; labellum with a large, reniform, emarginate middle lobe and rotund lateral lobes, yellow, with few reddish spots on the base. Mex. B. 3:116.

28. **Batemanniànum,** Parm. Pseudobulbs large, 4–5 in. long, with sheathing lvs. at the base: lvs. oblong-ensiform, 2 ft. long: scape erect, 6–8 ft. long; sepals lanceolate, undulate, reddish brown, slightly marked with yellow; petals similarly colored, spatulate and very much undulate; labellum brilliant yellow, with the crest marked with brown; lateral lobes small, rounded; middle lobe large, reniform, emarginate. Brazil. F.C. 3.137.—Related to *O. altissimum.*

29. **Harrisoniànum,** Lindl. (*O. Harrisiànum,* Hort.). Pseudobulbs subglobose, 1-lvd.: lvs. linear-oblong, acute, fleshy and recurved: panicle about a foot high, erect, with the st. and branches gracefully curved; sepals and petals linear, obtuse, yellow, spotted with purple-brown; labellum yellow, longer than the sepals, with small lateral lobes and a subreniform, emarginate middle lobe. Autumn. Brazil. B.R. 1569. L.B.C. 20:1917. R.B. 18:253. O. 1912, p. 8. G.W. 11, p. 518; 14, p. 519.

30. **leucochìlum,** Batem. Pseudobulbs sulcate, ovate, compressed, 2–4 in. long: lvs. sword-shaped, 1 ft. or more in length: scape 3–4 ft. high, with numerous branches on which the fls. are loosely scattered; sepals and petals oblong, obtuse, green, blotched with reddish brown; labellum pure white; lateral lobes small, rounded; middle lobe broadly reniform, emarginate. Autumn. Guatemala. F.S. 5:522. P.M. 7:241. G. 28:387. J.H. III. 43:215.—A noble species, with the habit of *O. Baueri.* Panicles 6–9 ft. long. Var. **spléndens** is listed.

31. **ornithorhýnchum,** HBK. Fig. 2580. Pseudobulbs oblong, compressed, 2–3 in. long, 2–3-lvd.: lvs. grass-like, 8–12 in. long: stalks 1 ft. long, slender and arched, many-fld.: fls. scarcely 1 in. across, soft rose-purple; sepals linear-oblong, wavy; petals oblong and a little broader; labellum pandurate, with small lateral lobes and a larger dilated, emarginate middle lobe. Fragrant. Autumn and winter. Mex. B.M. 3912. B.R. 26:10. F.C. 3:136. R.H. 1876:230.—This is an easily grown, free-flowering plant of dwarf, compact habit. Its soft rose-purple color is very delicate and unusual in the genus. Var. **albiflòrum,** Reichb. f. (var. *álbum,* Hort.). Fls. whitish, with only the calli yellow. F.M. 1880:398. G.C. III. 16:781. J.H. III. 29:399. G.M. 38:18. There is also a variety called **màjus.**

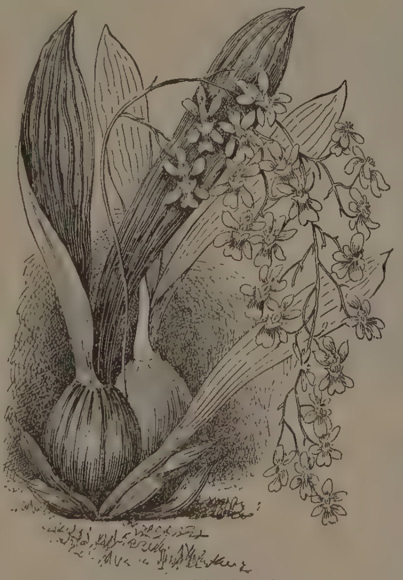
32. **divaricàtum,** Lindl. Pseudobulbs compressed, each with a fleshy, oval, apiculate lf.: scape 1½ ft. high, with the branches of the panicle extremely divaricate; sepals and petals oblong-spatulate, greenish yellow, spotted with purple toward the base; labellum yellow, spotted with red; lateral lobes large, half-rotund; middle lobe smaller, emarginate. Autumn. Brazil. B.R. 1050. L.B.C. 13:1212. P.M. 3:4.—A floriferous species easily recognized by its singular oval, fleshy lf. and the divaricate panicle.

33. **pulvinàtum,** Lindl. Panicle very much branched, in a loose, spreading manner, weak, 8–9 ft. long; fls. yellow, with the sepals and petals blotched with red; segms. obovate, acute; the 2 parts of the labellum nearly equal; lateral lobes rotund-crenate and crisp; middle lobe undulate, crest a villous cushion. Summer. Brazil. B.R. 25:42.—One of the largest of the oncidiums. The fls. last a long time. Var. **màjus,** Hort., is said to be desirable.

34. **Wárneri,** Lindl. (*Odontoglóssum Wárneri,* Lindl.). Pseudobulbs ovate, somewhat angular: lvs. linear-lanceolate: raceme short, few-fld.; sepals oblong; petals a little wider; all white or yellowish, striated with rose-purple; labellum brilliant yellow; lateral lobes subquadrate; middle lobe deeply divided into 2 rounded lobes. Autumn. Mex. B.R. 33:20 (var. *purpuratum,* Lindl.).

35. **maculàtum,** Lindl. Pseudobulbs ovate, compressed, 4-angled, 2-lvd.: lvs. broadly linear-oblong: fls. 1¼ in. across, yellow, spotted with deep purple; sepals and petals subequal, rather fleshy, ovate-subacuminate; labellum oblong-apiculate, the lateral lobes forming 2 large teeth near the middle; middle lobe ovate, sulfur-yellow, base marked with few red lines, claw with 4 horn-like plates. Winter. Mex. B.M. 3836 (var. *ecornutum*) and 3880. B.R. 24:44. F.C. 2:57 (all as *Cyrtochilum maculatum*).

36. **Límminghii,** Morr. Pseudobulbs oval, compressed: lvs. oblong, acute, mottled: raceme 1–2-fld., erect, several times longer than the small lvs.; fls. yellow, spotted and banded with brown; sepals and petals lanceolate, the lower pair larger; labellum with large, auriculate lateral lobes and a transversely broadened, subreniform, emarginate mid-lobe, spotted with red. June, July. Caracas. F.S. 18: 1827.—A pretty dwarf plant with the habit of a sophronitis.



2580. Oncidium ornithorhynchum. (×¼)

37. **cheiróphorum,** Reichb. f. Pseudobulbs 1 in. long, ellipsoid: lvs. 3–6 in. long, linear-lanceolate: scape bearing a dense panicle longer than the lvs.; fls. about ½in. across, entirely bright yellow, with greenish sepals; sepals and petals small, rounded-ovate, spreading or reflexed; labellum much larger, with three large lobes, the middle lobe notched. Colombia. B.M. 6278. G.C. 1871:168, desc. J.H. III. 65:591; 68:575.

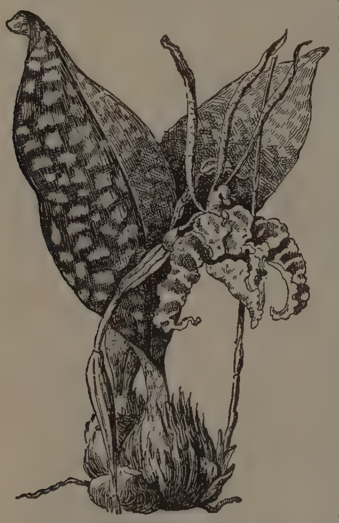
A. *Plants dwarf, scarcely over 8 in. high.*
  B. *Labellum with 3 equal lobes* ......38. **pumilum**
  BB. *Labellum with small lateral and a 4-parted middle lobe*............39. **Crista-galli**
AA. *Plants large.*
  B. *Wings of the column narrow, falcate*.........................40. **bicallosum**
  41. **Cavendishianum**
  BB. *Wings of the column fleshy, rotund, reniform, etc.*
    C. *Labellum pandurate, with triangular lateral lobes*............42. **Lanceanum**
    43. **carthaginense**
    CC. *Labellum reniform, with small blunt lateral lobes*............44. **luridum**

38. **pùmilum,** Lindl. A small plant about 6 in. high, without pseudobulbs, and with oblong, leathery lvs.: infl. a small, branched panicle, scarcely longer than the lvs.; sepals and petals obovate, yellow, spotted with brown; labellum yellow, rounded, trifid. Spring. Brazil. B.M. 3581. B.R. 920. L.B.C. 18:1732. J.H. III. 47:459.

39. **Crísta-gálli,** Reichb. f. (*O. iridifòlium*, Lindl., not HBK.). Lvs. radical, cuneiform-ligulate, 2–3 in. long: fl.-sts. several, 1–2-fld., slightly exceeding the lvs.: fls. yellow, with few red spots at the base of the segms. and labellum; sepals lanceolate, acute; petals oblong, crisp, much wider; labellum large; lateral lobes oblong-cuneate; middle lobe divided into 4 lobes, of which the inner 2 are smaller. B.R. 1911.—A very small, neat plant.

40. **bicallòsum,** Lindl. Pseudobulbs none: lvs. large, oblong-lanceolate, keeled, thick and leathery: panicle many-fld., variable in size; fls. 2 in. diam.; sepals free, obovate, concave; petals oblong-obtuse, undulate; all rich yellow or honey-colored, bordered with cinnamon-color; labellum with small, narrow lateral lobes, and a pair of tubercles for a crest; middle lobe large, transversely expanded, emarginate, subcordate. Autumn and winter. Guatemala. B.M. 4148. B.R. 29: 12. I.H. 12:458.

41. **Cavendishiànum,** Batem. Pseudobulbs none: lvs. fleshy, broadly lanceolate, 1–1½ ft. long: scape 4 ft. high, erect, with a dense panicle about 1 ft. long; sepals and petals oblong-obtuse, greenish yellow, with bright chestnut spots; labellum yellow; lateral lobes rather large, spreading, rounded, narrowed to a claw; mid-lobe broadly reniform and deeply emarginate. Guatemala. G. 27:164. G.W. 3, p. 471.—Grows very slowly.



2581. Oncidium Papilio. (×⅓)

42. **Lanceànum,** Lindl. Pseudobulbs wanting: lvs. fleshy, oblong, acute, 1 ft. long and about 3 in. broad: scape stiff, erect, branched above and 1 ft. or more in length; fls. 2–3 in. across, numerous; sepals and petals oblong, obtuse, fleshy, concave, yellow, marked and barred with chocolate-brown or crimson; labellum narrow in the middle, with the 2 lateral lobes forming a hastate base, middle lobe broadly expanded, cuneate. The color of the labellum is variable, usually rose in front, becoming violet toward the base. Summer. British Guiana. B.R. 1887. F.S. 18:1842, 1843. P.M. 4:169. F.C. 2:79. G.C. II. 21:609; III. 54; 279. G. 31:613. G.W. 10, p. 403. Var. **supérbum,** Hort., is described as a superior variety. Var. **Louvrexiànum,** Hort. (*O. Louvrexiànum*, Hort.). A variety with yellow fls., prettily spotted and marbled; labellum yellow at the base, white in front.

43. **carthaginénse,** Swartz (*O. Hénchmannii*, Lodd. *O. ròseum*, Lodd. *O. undulàtum*, Salisb. *O. sanguíneum*, Lindl.). Pseudobulbs obsolete: lvs. solitary, oblong, acutish: panicle 3 ft. long and loose; fls. small, whitish, marked and blotched with red and bordered with yellow; sepals and petals oblong-ovate, free, waved; labellum with horizontal, triangular lateral lobes and a fan-shaped middle lobe, crimson, with a yellow border. Summer. Trop. Amer. B.M. 3806 (as *O. Hunteanum*). F.C. 3:97 (as *O. luridum* var. *Henchmannii*).

44. **lùridum,** Lindl. Lvs. elliptical, thick, rigid, dull green, 15 in. long: scape slender, 3 ft. high, much branched and many-fld.; fls. nearly 1½ in. diam., dark green or olive-green, with indistinct darker spots; sepals clawed, undulate, crenate, obtuse, warted on the back, the upper one rotund, the others spatulate-oblong; petals larger and without warts; labellum reniform, almost plane. S. Amer. B.M. 3603. B.R. 727.—The panicle is said to grow to a height of 9 ft. A var. **ròseum,** Hort., is said to have rose-colored fls., spotted with white and bordered with yellow. Var. **guttàtum,** Lindl., has yellow fls. spotted with orange. B.R. 25:16.

45. **Papílio,** Lindl. Butterfly Orchid. Fig. 2581. Lvs. oblong, very leathery, olive-green, mottled with purplish brown, 6–8 in. long: peduncle 2–3 ft. long, flattened and jointed, producing fls. several years in succession; fls. 4–5 in. long and 2½ in. across; dorsal sepals and petals erect-linear, with a small lanceolate expanded portion, brown, with bands of yellow; lower sepals lanceolate-falcate, curved downward, yellow, with heavy bands of brown, labellum pandurate, usually plane, with the middle lobe rounded, transversely broadened, emarginate, yellow, with a broad band of brown around the margin; wings of the column toothed. Fls. at any season. W. Indies. B.M. 2795; 3733 (var. *limbatum*). B.R. 910. L.B.C. 11:1086. F.S. 9:920–2. P.M. 5:175. F.C. 1:12. F. 1842:49.—Variable in color of fls. and lvs. Lvs. sometimes green on the upper surface. Var. **Éckhardtii,** Lind. All parts of the fl. very large; sepals and petals golden yellow, barred with red; labellum yellow, with a broad margin of brown. I.H. 30:500.

46. **Krameriànum,** Reichb. f. This species is much like *O. Papilio*. Pseudobulbs rounded, 4–7-angled: st. terete: petals and dorsal sepals shorter than in *O. Papilio*, apex more distinctly dilated; lateral sepals golden yellow, spotted (not banded) with cinnamon-brown, crisp, undulate, finely toothed; labellum very crisp and undulate, finely toothed, pale yellow, with a narrow band of cinnamon-brown spots around the margin; column-wings entire. Cent. Amer. F.S. 19:1956. I.H. 41, p. 206. Gn. W. 20:738.

47. **Jonesiànum,** Reichb. Plants with fleshy, rush-like lvs. 3–12 in. long and usually hanging downward: fl.-sts. 6 in. to 2 ft. long, the largest bearing about a dozen fls. 2 in. across; sepals and petals oblong, wavy, cream-colored, with sepia-brown spots; labellum white, yellow at the base, with a few crimson spots near the isthmus; middle lobe large, subreniform, 2-lobed, wavy; lateral lobes toothed. Fls. at various seasons. Paraguay. B.M. 6982. R.B. 15:7. Gn. 31:148.—The handsomest of the round-lvd. species.

48. **Cebollèta,** Swartz (*O. juncifòlium*, Lindl.). Pseudobulbs very small, each with a single, terete, obscurely furrowed lf.: lvs. 1 ft. long, spreading, harsh in texture: panicle rigid, erect, about 2 ft. high; sepals and petals nearly equal, obovate, greenish yellow, spotted with red; labellum large, bright yellow; lateral lobes broadly obovate; middle lobe broadly obovate or subreniform, undulate, notched in front. Spring and summer. Brazil. B.M. 3568. B.R. 1994; 28:4 (as *O. longifolium*).

49. **triquètrum,** R. Br. (*Cymbídium triquètrum*, Swartz. *Epidéndrum triquètrum*, Swartz). Pseudobulbs none: lvs. few, 4–6 in. long, triquetrous and grooved: scape about as long as the lvs., purplish, bearing a raceme of 10–12 medium-sized fls.; sepals broadly lanceolate, the lower pair united, purplish green; petals ovate, white, tinged with green and spotted with purple; labellum cordate-ovate, constricted near the middle, white spotted with purple; crest orange. Autumn. Jamaica. B.M. 3393.

LXXVII. Onion.—The Prizetaker, a handsome pale yellow popular variety.

O. abortìvum, Reichb. f. Greater number of fls. abortive; perfect fls. pale yellow with chestnut-brown markings. Venezuela. G.C. III. 46:322.—*O. anfráctum,* Rolfe. Scapes rather slender, about 3 ft. long; fls. bright yellow, with dark brown bars on sepals and petals. Venezuela.—*O. ansíferum,* Reichb. f. Sepals and petals oblong-obovate, free, crisp; labellum with ligulate lateral lobes and a reniform, emarginate middle lobe, golden yellow, with 2 dark brown bars at the base, flaccid. The sepals and petals are greenish, with yellow tips. Colombia.—*O. anthocrène,* Reichb. f. Fls. yellow, brown-barred, fragrant; sepals cuneate-oblong, undulate-crisped, acute, about equaling the petals; lip with lateral lobes deflexed, the isthmus narrow, the front lobe broad, reniform, 2-lobed. Colombia.—*O. armillàre,* Lindl. Sepals and petals lanceolate, acuminate; crest of 3 flexuous keels. Peru. Gt. 7:296.—*O. Baldeviàmæ,* Reichb. f. (O. Balderramæ, Reichb. f.). Panicle ample; dorsal sepals rounded, clawed, crisp, yellowish olive-brown with a yellow border; lower sepals longer clawed, cuneate-oblong, unicolored; petals oblong, short-clawed, crisp, nearly complicate, smaller than the sepals, yellow, with brown blotches; labellum hastate, ligulate, obtuse. Summer. Colombia.—*O. Bállii,* Rolfe. Scape about 12 in. long; panicle about 7 in. long, many-fld.; fls. small, bright yellow with brown markings on lower half of sepals and petals; base of lip dark shining brown. Habitat (?).—*O. Beyrodtiànum,* Schlecht. Allied to O. varicosum and O. flexuosum but distinguished by the crest of the lip, which is simple, quadrate-rounded, and scarcely warty above the base.—*O. bicotiénse,* Hort. ex-Lindl.=Odontoglossum sp.—*O. bidentàtum,* Rolfe. Scapes slender, about 6 ft. long; fls. medium-sized, yellow marked with brown. Ecuador.—*O. bifòlium,* Sims. Fls. yellow, the dorsal sepal and petals brown-barred, undulate, the lateral sepals united below; lip broad, reniform, 2-lobed. Argentina. G.W. 10, p. 80.—*O. cæsium,* Reichb. f.=O. Geertianum.—*O. caloglóssum.* Reichb. f. A supposed natural hybrid between O. Marshallianum and O. Forbesii. Sepals and petals yellow, with dark brown stripes nearly confluent on the petals. Brazil. Var. *cóncolor* is a yellow-fld. form.—*O. cardiochìlum,* Lindl. Panicle large, lax-branching; fls. numerous, about 1½ in. across; sepals and petals brown; lip yellow. Colombia.—*O. Chárlesworthii,* Hort. (supposed to be natural hybrid). Fls. racemose, chestnut-red, lip yellow at base. G.C. III. 45:377.—*O. Clæsii,* Rolfe. Sepals bright chocolate-red; petals and lip deep carmine, shaded with violet. Colombia.—*O. corynephòrum,* Lindl. Sepals and petals rounded, undulate, light rosy purple, broadly white-margined; lip orbicular, deep violet-purple with a yellow base. Peru. G.C. III. 38:340.—*O. cristàtum,* Beer=Odont., cristatum.—*O. Fóstermannii,* Hort.=(?).—*O. fuscàtum* Reichb. f.=Miltonia Warszewiczii.—*O. Gárdneri,* Lindl. (O. Gardnerianum, Hort.). Resembles O. crispum and O. Forbesii. Fls. lemon-yellow, spotted and barred with chestnut-brown on the sepals and petals; labellum broad, yellow, margined with the same color; all segms. undulate, crisp. Brazil. G.C. II. 16:86. F.M. 1880:401. J.H. III. 47:415; 56:489. This is probably O. curtum, Lindl., which should be referred to this species.—*O. Geertiànum,* Morr. (O. cæsium, Reichb. f.). Species probably based on a variety of O. reflexum.—*O. graminifòlium,* Lindl. (O. Wrayæ, Hook.). Fls. panicled, yellow; sepals and petals blotched with deep brown, oblong-elliptic, acute; lip large, broadly obovate, lobed. Mex. B.M. 3854.—*O. Gravesiànum,* Rolfe. Pseudobulbs broadly oblong-compressed, 3 in. long: lvs. elliptic-oblong, 4 in. long: panicle large, branching; fls. 2 in. across, yellow, spotted with brown; dorsal sepals spatulate; lateral sepals lanceolate-oblong, united at base; petals obovate, wider than the sepals; labellum pandurate, with small spatulate lateral lobes and a broadly orbicular-ovate, undulate middle lobe. Brazil. R.B. 21:73. G.C. III. 11:651. Near. O. crispum.—*O. hastàtum,* Lindl. Sepals and petals yellow, spotted with brown; labellum pale yellow. Mex.—*O. hýbridum*=O. tigrinum × O. lamelligerum.—*O. illústre* is a supposed natural hybrid between O. leucochilum and O. maculatum.—*O. Jánssenii*=O. tigrinum × O. Forbesi.—*O. Johniànum,* Schlecht. Lip 3-lobed, shorter than sepals, lateral lobes very obtuse, about ¼in. long. Brazil.—*O. lamellígerum,* Reichb. f. Fls. large; sepals light brown, margined with yellow; petals very crisped, light yellow; lip narrow, light yellow, stained with purple. Ecuador.—*O. lancifòlium,* Lindl. (O. sessile, Lindl. & Paxt.). Pseudobulbs oblong: lvs. short, pale green: panicle much branched and bearing a large number of fls.; sepals and petals large, obtuse, yellow, spotted with cinnamon-brown at the base; labellum large, of the same color. Ecuador.—*O. Lávenderi.*—*O. Lawrenciànum,* Reichb. f.=Brassia Lawrenciana.—*O. Leopoldiànum,* Rolfe. Fls. panicled, numerous; sepals and petals white, with a large purple spot; lip violet-purple, the disk yellow. Andes. G.M. 48:711.—*O. Lòwii* is a supposed natural hybrid. Infl. over 6 ft. in length; fls. numerous, yellow spotted with brown.—*O. Mántinii* is a supposed natural hybrid between O. Marshallianum and O. Forbesii. Sepals and petals yellow, centers covered with rich chestnut-brown; lip clear yellow, with few purplish brown spots. Var. *Lòwii,* Hort., has the fls. unusually large.—*O. McBeaniànum*=O. superbiens × O. macranthum.—*O. microchìlum,* Batem. Fls. colored like O. crispum, panicled; sepals free, and, like the petals, oblong, undulate, and retuse; lip nearly round, cordate, barely half as long as the sepals. Guatemala.—*O. Mùlleri,* allied to O. corynephorum and perhaps a form of it. Sepals and petals white, tinged with rose; lip rose-purple, with a cream-yellow crest. Peru.—*O. murìnum,* Reichb. f. A species with numerous small yellow fls. borne in panicles.—*O. oblongàtum,* Lindl. Fls. yellow; petals flat, undulate, with a few reddish brown basal bars. Mex.—*O. obryzàtum,* Reichb. f. & Warsc. Fls. golden yellow, spotted with brown, borne in a much-branched panicle. Peru. Said to be an elegant winter-flowering orchid.—*O. platybúlbon,* Regel. Panicle about 4 in. long; fls. rather crowded; sepals and petals obovate-oblong, olive-yellow; lip yellow. Brazil. Gt. 52:1518.—*O. pulchéllum,* Hook. Fls. racemose; sepals and petals whitish, the lateral sepals united; lip large, quadrate, 4-lobed, flushed with rose and with a few yellow spots. Jamaica. B.M. 2773.—*O. punctàtum* is a supposed natural hybrid between O. Forbesii and O. Gardneri.—*O. Reichenbachii,* Lindl. Colombia.—*O. Rivieriànum,* Hort. Peduncle about 2½ ft. long, bearing 15–20 fls.; sepals lanceolate, white, spotted with brick-red and black; lip golden-yellow, spotted. Brazil.—*O. robustíssimum,* Reichb. f. Fls. panicled; sepals and petals yellow at top, brown at base; lateral lobes of lip serrate, the front lobe emarginate, marked with cinnamon bars. Brazil. G.C. III. 38:45.—*O. ròseum,* Beer=Colchioda rosea.—*O. rupéstre,* Lindl. Fls. numerous, in a branched panicle 2 ft. high, brilliant yellow, spotted with brown. Peru. Said to be desirable.—*O. Russelliànum,* Lindl.=Miltonia Russelliana.—*O. Sánderæ,* Rolfe. Lvs. brown-marbled: fls. on a long scape; dorsal sepal linear-lanceolate, acute, reddish brown, about 3 in. long, the lateral sepals oblong, crisped, yellow, brown-spotted, a little shorter, nearly 2 in. wide; petals linear-lanceolate, similar to dorsal sepal; lip 3-lobed, the lateral lobes rounded, crisped, yellow, brown-spotted, the middle lobe orbicular, clawed, crisped, about 1½ in. across. Peru. B.M. 8374.—*O. sarcòdes,* Lindl. Pseudobulbs sub-cylindrical, 3 in. long, 2–3-lvd.: lvs. lanceolate: panicle branched, many-fld., slender; fls. large, yellow, spotted with brown; sepals free, obovate; petals larger, clawed, obovate-spatulate, repand; labellum with small serrate lateral lobes; middle lobe large, emarginate, undulate. Brazil. I.H. 21:165. J.H. III. 58:92. Near O. ampliatum. Var. *ornàtum,* Hort., differs in the color of its fls.—*O. Schilleriànum,* Reichb. f. Trop. Amer.—*O. Schlímii,* Lind. A large, rampant species, with yellow fls. marked with brown, about 1 in. diam. Nov. Cent. Amer.—*O. Stánleyi,* Hort., is a natural hybrid supposedly between O. Marshallianum and O. curtum. J.H. III. 53:267.—*O. stellígerum,* Reichb. f. Sepals and petals oblong-ligulate, stellate, yellowish, with many brown dots; labellum with short, obtuse-angled lateral lobes, a narrow isthmus, and a cordate, rotund, cuspidate middle lobe, pale yellow, with a darker callus. Mex. Near O. hastatum.—*O. Vólvox,* Reichb. f. Venezuela.—*O. Warszewíczii,* Reichb. f. Pseudobulbs rounded, compressed: lvs. 1 ft. long, thin: scape stout, with an 8–13-fld. panicle; fls. yellow, with purple spots and the middle of the labellum blood-red; upper sepals lanceolate, acute, crisp; lower pair oblong, shorter than the labellum, united; petals oblong, much wider than the dorsal sepals; labellum with auriculate lateral lobes, and a reniform bifid middle lobe. Colombia.—*O. Wéltonii,* Hort.=Miltonia Warszewiczii.

HEINRICH HASSELBRING.
GEORGE V. NASH.†

ONCÒBA (Arabian, *onkob;* name of a North African species). *Flacourtiàceæ.* Glasshouse woody plants, grown sometimes for the bloom.

Tropical and subtropical shrubs or small trees, sometimes spiny: lvs. alternate, without stipules: fls. terminal, solitary or clustered, white, reddish or yellow, large for this family, polygamous; sepals 3–5 and petals 5–10; stamens very numerous, inserted in many rows beneath the ovary; filaments filiform; anthers linear, 2-celled, attached to the base, erect, opening at the sides; stigma dilated, notched; ovary free, 1-celled; style cylindrical: berry leathery, pulpy within; seeds 1, few, or many, sometimes used as ornaments by the natives.—Species 25 or more, Trop. Amer. and Trop. Afr., also S. Afr.

Kraussiàna, Planch. A branching shrub without thorns, young lvs. and shoots slightly pubescent, the older branches having a rough ash-colored bark: lvs. elliptic-oblong to oblanceolate, obtuse or subacute, entire, 2 in. long, with midrib, pinnate and netted veins, somewhat pale on under side: peduncles terminal or opposite the lvs., 2–3 in. long; fls. erect, solitary, about 2 in. across, white; sepals roundish and very concave; petals twice as long, spreading, with narrow claws, cuneate at base, broadly obovate, with scattered, woolly hairs; anthers pointless; stigma 5–6-rayed; ovary hairy. Procurable in S. Calif.—This makes a very fine pot-plant in greenhouse temperature, flowering in spring. It is also useful for subtropical bedding. Prop. from ripewood cuttings, also from seeds. Give the plant a sunny position, and plenty of water while new growth is making.

Roùtledgei, Sprague (*O. spinòsa* var. *Roùtledgei,* Hort.). Shrub, to 20 ft., with strong axillary spines: lvs. alternate, short-petioled, oblong or elliptic-oblong, crenate-serrate, nearly glabrous: fls. white, fragrant, about 2 in. across, one or two together on the old wood; sepals 4, reflexed under the fr.; petals about 8; stamens very many. Trop. Afr. G.C. III. 49:322, 330. G.M. 54:277 (as *O. speciosa* var. *Routledgei*). L. H. B.†

ONCOSPÉRMA (Greek, *tumor-shaped seed*). *Palmàceæ,* tribe *Arèceæ.* A group of little-known palms not in cultivation in America outside of botanic gardens.

Trunk low, very spiny: lvs. equally pinnate; lfts. ensiform-acuminate, entire, equidistant or somewhat clustered in 2 or more series, the veins scaly beneath; rachis convex on the back, with a blunt keel above: spadix from between the lvs., monœcious, crowded with sessile, spirally arranged fls.: fr. small. Oncosperma differs from Euterpe in the small, acute sepals: stamens 6–12, the anthers erect: albumen ruminate.—Species 6. Trop. Asia. Cult. as in Areca.

fasciculàta, Thwaites. Caudex at length 30–40 ft. high, 5–6 in. diam.: lvs. 18 ft. long; pinnæ fascicled, 12–18 in. long, 1–2 in. wide, lanceolate, long-acuminate, the tips drooping; sheath 2½ ft., armed and scurfy: fr. globose, black-purple, ½in. diam., much like a black currant. Ceylon.

filamentòsa, Blume (*Arèca Nìbung*, Griff. *A. tigillària*, Jack). Trunk 30–40 ft., armed with long black spines: lvs. 10–12 ft. long, drooping; lfts. 2 ft. long, narrow, acuminate, scurfy beneath: fr. spherical, ⅗in. diam. Malaya. N. Taylor.†

ONION. All the onions of common or general cultivation are forms of one variable species, *Allium Cepa* (see *Allium*, Volume I). It is probably native to southwestern Asia, but it has been long domesticated and has varied much. Other cultivated species are *A. fistulosum* (Fig. 2583), *A. Porrum* (Fig. 2484), and *A. Schœnoprasum* (Fig. 2585).

The onion is grown primarily for its bulbs, but the leaves are sometimes used as seasoning and in stews. Under long-continued cultivation and selection, the bulbs have developed into large and shapely organs. Now and then the bulb does not develop and the neck (or stalk just above the bulb) remains relatively thick: such onions are "scullions." Seeds from poorly selected or deteriorated stock may be the cause of scullions: they are to be considered as reverted or run-down forms. Sometimes scullions result from very wet soil, whereby the plants grow too much to top. Seeds grown in the South or in a long-season climate tend to produce plants in short-season regions that do not "bottom" before caught by frost.

2582. Onion in flower.

The onion is one of the hardiest of vegetable-garden plants. In the southern climates it is grown largely as a winter crop. In the northern states and Canada the seeds are sown or the bulbs planted as soon as the ground can be fitted in the spring. It is always best, if possible, to prepare the ground in autumn in order that the seeds may be sown on the first approach of warm weather. When onions are grown from seeds, it is essential that the ground be fine and loose, and all surface stones and litter removed. The seeds are small and do not germinate quickly. The young plants are surface feeders. If the seed is sown late or if the ground is droughty, the plants will either perish or make no headway. Land that is foul with weeds should not be planted to onions, for the young onion plants cannot withstand such competition. In the old-fashioned gardens, it was the custom to plant onions in short rows crosswise of raised beds. This entailed an endless amount of small hand labor and usually resulted in the expenditure of more time and effort than the onions were worth. The better method is to grow the plants in long rows which are far enough apart to admit of the use of a wheel-hoe. Even when a small quantity of onions is desired, it is better to place them all in one row than to have many short rows. With the best of land and management, and with the use of wheel-hoes, more or less finger work will be necessary in order to bring the crop to full perfection. The seed may be sown thick in the home garden, and as the young plants begin to crowd, they should be thinned. The plants taken out in the second and third thinnings may be used on the table (Fig. 2586). It is very important that the best grade of seed be used, for the onion deteriorates rapidly from seed which is not well grown nor carefully selected. There are great numbers of varieties. For early use and for variety, great numbers of kinds may be selected from reliable seed catalogues. Some of the quick-growing southern onions are excellent for early use. Forms of onions are shown in Fig. 2587.

2583. Welsh onion—Allium fistulosum.

2484. Leek—Allium Porrum.

There are two general methods of propagating the onion—by seeds and by bulbs. Onions grown from seeds are ordinarily called "black seed onions," although there is no onion seed that is not black. The main field crop is grown from seeds, as explained in the articles which follow. The onion seed of the market is produced from full-grown and typical bulbs of the desired variety. These bulbs are grown from seed and are kept over winter as other onions are. In the spring they are planted in rows 2 feet apart and as near together in the row as they will stand. They send up a flower-stalk which blooms in early summer (Fig. 2582), and the seed is harvested.

Propagation by bulbs is employed for the purpose of securing early onions for home use or for the special early-season trade. Until within recent years, all the very early or bunch onions were raised from bulbs, but recently a so-called "new onion-culture" has come into vogue, which consists in sowing seeds in hotbeds or coldframes and transplanting the young plants. Bulb-propagation is of three general categories: (1) The use of bulbets or "top onions" which appear on the top of the flower-stalk in the place of flowers; (2) the use of bulbels or separable parts of an onion bulb, known as "multipliers," or "potato onions;" (3) the use of ordinary bulbs which are arrested in their growth, known as "sets."

2585. Chive.—Allium Schœnoprasum.

Bulblets, or top onions, are shown in Fig. 2588. If one of these bulblets is planted in the spring, it quickly produces a young bulb, and the growing bulb may be pulled at any time and eaten. If allowed to remain in the ground, however, it sends up a stalk (either the first or second year) which bears a cluster of bulblets, sometimes mixed with flowers, on its top. There are two or three strains of top onion on the market, although the leading ones are the white and the red, these names applying to the color of the bulblets. The so-called "Egyptian onion" is a top onion; also the "tree onion."

Multipliers are shown in Figs. 2589, 2590. Instead of containing a single "heart" or core, as in most onions, it contains two or more. When the onion is planted, each of these cores or bulbels sends out leaves and grows rapidly for a time; that is, the old or compound bulb separates into its component parts. The growing bulbels may be pulled and eaten at any time. If allowed to remain in the ground, each of these bulbels will make a compound bulb like that from which it came. Sometimes flower-stalks are produced from multiplier or potato onions. The best results with multipliers are secured when the bulbels are separated on being planted, for each one has room in which to grow. Two or three kinds of multiplier onions are known, the variation being chiefly in the color of the bulb.

Onion sets are merely ordinary onions which are arrested in their growth, and when planted will resume growth. They are grown from seed. The seed is sown very thick on rather poor land, so that the young bulbs soon reach the possibilities of their growth; they mature when still very small. These small bulbs or sets are then harvested and kept over winter, and used for planting the following spring. When planted, they grow rapidly and may be pulled and used for the table. If allowed to remain in the ground, they send up flower-stalks and produce seeds as do common onions. Sets are not allowed to seed, however, since the seeds from sets would probably produce an inferior race of onions. Any variety of seed-bearing onion may be grown and propagated as sets, although there are relatively few that give uniformly good results. In the trade, onion sets are usually designated as yellow, red, or white. In order to secure good results from onion sets, it is essential that the sets be small and firm. They should not be over ½ inch in diameter, if they are of the best. If they are much larger than this, they tend to run to seed rather than to produce bulbs. Sometimes the very small and inferior onions are saved from the regular crop and are used as sets the following spring. Such sets are generally known as "rareripes." Usually they do not give the best results.

The varieties of onions are numerous. Some of the forms of bulbs are shown in Fig. 2587. In 1889 ("Annals of Horticulture") seventy-eight varieties of "seed" onions were offered by American dealers, and also about twenty kinds of multipliers, potato onions, and sets. For purposes of careful scientific study, the varieties may be classified into geographical races, but for purposes of description they may be assembled into groups characterized by such arbitrary features as form and color of bulb. Goff (Sixth Report of New York State Experiment Station, for the year 1887) classifies first by shape of bulb and then by color. He makes four primary groups: bulb oblate, spherical, top-shape, oval or pear-shape. Each of these groups is divided in three sections: color white, yellow or brownish, red or reddish. Another classification (Bailey, Bull. No. 31, Mich. Agric. College, 1887) makes three primary sections on methods of propagation: propagated by division (multipliers), by bulblets or "tops," by seeds (or sets). The last section (seed onions) is divided into bulbs silvery white and bulbs colored, and these groups are again divided on shape of bulb.

When onions are grown continuously on the same land they are likely to become seriously affected with smut. Rotation of crops is the fundamental remedy. Sulfur and lime drilled into the soil with the seed at the rate of one hundred pounds sulfur and fifty pounds air-slaked lime to the acre, is also helpful. The smut may kill the young onion plants outright. The onion mildew causes wilting or blighting of the leaves, without the black pustules caused by the smut. Bordeaux mixture is the standard remedy; a "sticker" should be added to the mixture.

Aside from the chapters on onions in the vegetable-gardening manuals, there are special treatises, as Greiner's "Onions for Profit," and "The New Onion Culture;" Greiner and Arlie's "How to Grow Onions," the Orange Judd Company's "Onion Book," Gregory's "Onion Raising;" J. P. Underwood's "Onion Culture."

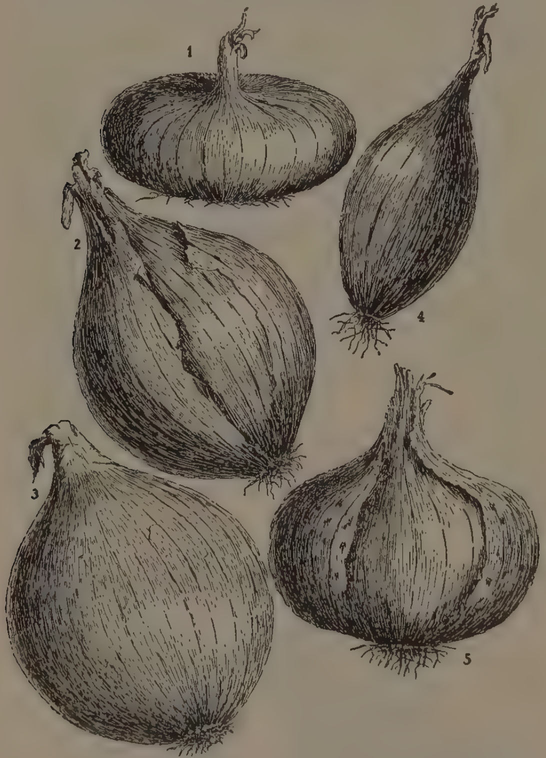
L. H. B.

The new onion-culture (transplanting process).

The idea of raising onions by growing seedlings in beds and transplanting to the open, which are the essential features of what has been termed "the new onion-culture," is not new. It has long been put in practice in the Bermudas, among the Portuguese growers in California, and in various places in Europe. This, however, does not detract from the fact that the writer, as well as W. J. Green, of Ohio, rediscovered (about 1889) this old plan or method of onion-growing, which was then unknown in their localities and also in most parts of the United States. There are only few, if any, modern innovations which have left an equally deep impression on our garden practices. The transplanting method is admirably adapted

2586. Bunch onions from the early spring sowing.

to the character of the large foreign onions, especially those of the Spanish type, and by it the American grower is enabled to produce bulbs in every way the equal of those large sweet onions which are imported from Spain and other foreign countries, and sold in our groceries at 5 to 10 cents a pound. Some of the onions now sold to the unsuspecting buyer in various places as "imported Spanish" may be really nothing more than these home-grown bulbs of the Prizetaker variety, and the buyer is not the loser by any means. This Prizetaker is perhaps the best of this class of onions to be grown by the transplanting process at the time of writing—large, of good shape, perhaps a little darker in color than the imported Spanish, and its equal in mildness of flavor. The newer Gibraltar is still larger, milder, a little later, not so good a keeper, but altogether one of the best onions which the home-grower, as well as the market-gardener who can sell his crop before late fall and at good prices, could produce.



2587. Forms of onions. *1*, flat; *2*, long globe; *3*, globe onion; *4*, oblong; *5*, oblate.

The plants should be started under glass (preferably in greenhouse) during January or February, sowing seed rather thickly in drills ½ or 2 inches apart, and using about an ounce of seed to 10 square feet of bed-surface. The soil should be sandy and very rich. Keep the plants in good growth, and as soon as the patch outdoors can be properly prepared in spring, set the seedlings in rows about 14 inches apart, and from 3 to 4 inches apart in the rows. Little hand-weeding will be necessary, but the wheel-hoe should be used freely. Green or bunching onions are also often grown in this way. For that purpose the plants are set more closely in the rows, not over 2 inches apart. Seed of the Prizetaker is mostly grown in the United States, while that of others is as yet all imported.

T. Greiner.

Commercial onion-culture in the North.

The soil for onion-culture should be a rich, moist, but not wet, loam with a subsoil of clay, or close compact sandy loam, not coarse gravel, as that lets the water leach out too quickly. Onions will stand a large amount of fertilizing, and there is little danger of getting the soil too rich. Soil that has been under cultivation for three or four years at least is much better than new land. The tendency of the latter is to produce too much top-growth and improperly ripened bulbs.

To prepare the soil, plow 10 or 12 inches deep, if the soil is of sufficient depth, or down to the subsoil. Care should be taken not to turn up much subsoil, or the crop will not mature evenly.

If the soil is poor, plow in 5 to 10 cords of stable manure to the acre, and spread on an equal amount of well-rotted manure after plowing, to be harrowed in. Unleached hardwood ashes is also a good fertilizer, especially on rather dry land, as it aids in the conservation of moisture. The action is quick, which makes it valuable where a little of the subsoil has been turned up in plowing, giving the young plants a good start, when, without it, they would be too light-colored and weak in growth. Ashes should be spread as evenly as possible, seventy-five to one hundred bushels to the acre on the ground after plowing, and harrowed in.

The harrowing should be thorough, using some kind of a disc or spring-tooth, for the first time over, with a Meeker or some other smoothing-harrow for the finish. It is impossible to get a good even stand of plants if the ground is rough or lumpy, while those that do grow are weak and puny on rough ground. Hand-raking is sometimes necessary to insure germination of seed in a satisfactory manner.

The drainage must be nearly perfect, to get best results. There should be no hollow places in the beds. Even on a sloping piece of land, the dead-furrows or alleys should be kept open to a depth of 8 or 10 inches, and evenly graded so the surplus water will all drain off. If there is a natural sag in the land which cannot be surface-drained, it is often practicable to underdrain so as to get satisfactory results; for there is no crop grown in the ordinary market-garden which will pay a larger percentage of return for underdraining, in nearly all locations. If the foliage is of a light color, and the crop does not ripen evenly, an underdrain will usually correct the trouble. The time to drain is when the ground is being prepared for planting, not after a heavy rain, when water is standing in pools over the field.

The time to plant is as early in the spring as the soil becomes in good working condition. The common spring frosts and snow flurries will do no harm if other conditions are right.

There are a few growers who can profitably grow their own seed, but the masses should buy. This should be done early, so that there may be no delay at planting time, and also that one may get the best stock obtainable. If one wants ten pounds or more, it is sometimes advisable to order from some one of the large seed houses of the country, but if there is a reliable local dealer who buys seed in bulk, one can often do better than to send direct to the large seed house, even on quantities of fifty to one hundred pounds. Be sure to know where the seed comes from, and if possible test it before planting. In any case, always buy the best seed obtainable, no matter if it costs double the price of other stock.

The sowing of the seed should be done with one of the standard garden seed drills, the first essentials of which are that the machine can be regulated to sow evenly and in the quantity desired without clogging. The machine should open a row, sow, cover, roll, and mark the next row, all at one operation. The machines which have a sliding piece at the bottom of the hopper, which opens and closes a diamond-shaped opening, are the best, as the operator can regulate exactly the amount of seed sown.

The seed should be sown in rows 12 to 14 inches apart, and at the rate of three and one-half to four and one-half pounds to the acre, according to soil and seed. A soil which produces heavy tops requires less seed than the drier, sandy soil which grows small tops. The plants should stand from 1 to 3 inches apart in the row. The seed should be sown from ½ to 1 inch deep, according to soil.

2588. Top onions. (×⅓)

Cultivation should begin as soon as the plants are up enough for the rows to be seen. Begin with a double-wheel straddle cultivator if one is at hand, setting the knives as closely as can be worked without covering the young plants, and continue as often as necessary to keep weeds destroyed and the ground loose on top until the plants are too large to get through. The last time through may be done with a single-wheel machine, which will throw a little earth up to the plants. A single-wheel machine may be used throughout the season, but the double-wheel is preferable for the first part of the work.

On light soil, a hand-weeder may be used with profit after the young plants have reached 3 to 5 inches in height. This works two rows at one passage, stirring the soil in the rows where the wheel-hoes do not work, and greatly reduces the amount of hand-weeding to be done. Of course, hand-weeding must be done as often as necessary to keep the beds clean.

Harvesting may be done in the following manner: If the crop ripens evenly, so that there are no green tops standing, the topping can be done most rapidly before the onions are pulled. By using a thin, sharp knife, taking the dry tops in one hand and cutting from the person, the work can be done quickly and well. Be careful not to tear the skin down the side. The length to cut the tops is a point of importance and must not be overlooked. If the tops are left too long they have a ragged appearance, and if too short, there is danger of causing the onions to rot in the tops, because of bruising or because of water having gone to the inside of the onions. The proper length is about ½ inch from the bulb; or, take an onion by the top, with the thumb and forefinger close to the bulb, and cut the top close to the fingers The pulling may be done by hand, but a puller made to fit a hand-cultivator is much more rapid and does not injure the bulbs. The puller is simply a curved knife with one or more fingers to move the bulbs slightly after the roots are cut. In light dry soil it works very well without any fingers.

Many growers prefer to pull the onions first, allowing them to dry a few days before topping. This is what should be done if the tops do not dry evenly, or if the crop is late and needs to be hurried; and is all right in any case, though not quite so rapid as the other way.

After the onions are topped, they should be gotten under cover as soon as possible. Let them dry a day or two if the weather is favorable and then pick them up and store in the curing-shed. If allowed to lie too long on the ground the skin peels off too much. The shed should have doors or ventilators at each end from top to bottom, so that the air can pass through freely and be free under the floor. If the floor is tight, with no circulation under it, lay some 2 by 4 scantling on the floor and lay a loose board floor over them without nailing; then take some pieces of 2 by 4 sawed just 1 foot long and nail them to the floor at even distances for posts to carry stringers for the next floor. Use 2 by 4 for the stringers; set them on edge, nail them to the posts and all is ready for the onions. This gives a space of 16 inches. Fill 12 inches (the length of the posts) and leave the 4 inches for air-space. Lay another floor and proceed as before, being careful to get the upper posts directly over the lower ones, or the stringers will break after two or three floors are in.

In handling the onions, bushel boxes are the most convenient. Pick them up in common baskets, leaving all small, defective, or odd-colored bulbs on the ground, to be picked up separately and sorted as occasion may require. Dump in the boxes, then drive along the side of the bed with a platform wagon, and load. Have a screen about 4 feet long by 2 feet wide made of narrow strips ½ to 1 inch wide and about 1 inch apart and the sides 10 inches high. Put legs on one end about 14 or 15 inches long and on the other end long enough to give it a sufficient incline to make the onions roll down freely. With an old coffee sack, make a bag like a sheet hung by the corners with hooks, to hang under the screen, in order to catch the dirt and leaves. Carry the boxes of onions directly from the wagon to the screen and pour them over it, moving the screen back as the floor is filled to the proper depth. This will take out all the dirt and most of the loose leaves, and make the onions come out of the shed in much better shape. They should lie in the shed until they are dry enough to peel off another skin, and rattle and crackle when the arm is run in among them.

If all has gone well, the crop should average 500 bushels to the acre on good land, or 600 bushels on very rich land, and 700 or 800 bushels on a single acre selected from the best part of a 10-acre field.

2589. A multiplier onion.

2590. Section of a multiplier onion.

There is an old saying, "the time to sell is when someone wants to buy." This is a very good rule to apply, unless one is prepared for cold weather or is reasonably sure of an advance in price. In a general way, it is best to ship in sacks of even size and not too large, one and three-fourths to two and one-fourth bushels. These points must be governed by the market. In sacking to ship, always throw out all defective bulbs and all of another color. In size, down to about 1½ to 1¼ inches in diameter is a good scale to use in a general way, but this point must also be governed by the market. Sell by sample so far as possible.

There are three varieties of onions which take the lead clearly above all others in the big markets of the country,—the White Globe, Yellow Globe, and Red Globe. These come under different names, as Southport Yellow Globe and Michigan Yellow Globe, but the object in view among seed-growers is to get bulbs as nearly globe-shaped as possible. The skin should be thick and two or three layers deep, to prevent bruising.

Irving C. Smith.

Onion-culture in the South.

Twenty years ago onion-growing from seed was not considered practicable, and by many it was considered impossible south of the Potomac. The introduction of varieties from southern Europe and more careful attention to details of the work have made onion-growing not only possible but often exceedingly profitable.

The eastern South consumes large quantities of the mild forms, such as the Bermudas. In the markets at Jacksonville, Florida, these are sold by the piece, frequently retailing at 5 cents and 10 cents each. The southern onion-grower must keep in close touch with the northern and foreign onion markets. In the humid regions of the South, there is a considerable risk from unseasonable rains. In the drier regions, such as a part of Texas, it becomes a very important and remunerative form of vegetable-growing. They have developed onion-growing most extensively and have organized the marketing arrangements most perfectly there.

2591. Red Bermuda.

The soil should be alluvial, sandy, and of a fine texture. A level tract, freed of all debris, and one that can be plowed deeply, is desirable. In the coast regions such land may be obtained in great abundance. It is frequently used for vegetable-growing, but large areas are still uncleared or are used for farm crops. In the hilly regions of the interior, onion lands must be sought mainly along rivers or old river-beds.

Undecomposed vegetable matter should not be applied immediately preceding the crop. Even cotton-seed meal should be used three weeks or more before the seed is sown and then carefully incorporated with the soil where the rows are to be, or if the rows are to be a foot or 14 inches apart the cotton-seed meal may be sown broadcast and cultivated in.

Seed-sowing in the field occurs in the uppper districts as early as the first of April or a little earlier, in the central district about the last of February, while in the Gulf region it may occur late in fall or any time during the winter, being gauged largely by the time required for the variety to mature, and the market to be met. It is a good rule to put on an abundance of seed, about twice as much as recommended in general, especially in the Gulf region. Many fields suffer from deficient stand more than from any other cause, and in some years it is the only cause for an unprofitable crop.

Good crops may be grown from sets, but the labor involved and cost of the "seed" is usually so great as to deter many from planting them. In using sets, they should be separated into three or four grades, the largest size maturing earliest and the smallest last. In most cases the smallest sets grow such inferior onions that they had better be discarded. This takes for granted that the sets were all grown at the same time and from the same seed in one field.

Nearly all the onion sets used in the South are shipped in, while they may be grown as well here as anywhere. In the Gulf region there is time enough to grow a crop of sets after the northern crop has been harvested and marketed. Thus in case of shortage in northern-grown sets, it is entirely practicable to ship the seed South, grow sets, and ship sets back in time for spring market.

Much has been written and spoken about raising the plants in a seed-bed and then transplanting to the field. While this may be practised successfully, the greater quantity of onions is raised by the old-fashioned method, i. e., by seeding in the drills where the plants are to mature bulbs.

In certain localities it is advantageous to plant out a seed-bed before the general field will permit working, and then transplant as soon as all conditions are favorable. In the upper districts of the South, seed may be sown in hotbeds as early as the first of February, and the plants may usually be set out by the first of April. In the central South, seed may be sown in protected coldframes as early as the middle of December, or in an open bed in February. The earlier plants may be transferred to the field by the last of February, or as soon as danger from frosts is past. In the Gulf region the seed may be sown during the fall in an open bed, and transplanting to the field may occur when plants are of proper size and favorable condition of weather prevails.

Harvesting is often attended with considerable difficulty, and in some cases special drying-houses have to be constructed to secure the crop in first-class condition. The crop is a perishable one, and must be pulled, gathered and shipped in as short a time as possible, when sufficiently mature.

There seems to be no generally accepted plan for marketing, the crop being placed in boxes, barrels or bags for shipping.

The following varieties have given good crops in the hands of expert growers and may be recommended for the entire South: White Bermuda, Red Bermuda, Prizetaker, Yellow Danvers, Giant White Italian, Giant Rocco, and Large Tripoli. Other varieties than those named here have given as good or better returns, but do not seem to have been so generally successful. Additions are Red Bermuda (Fig. 2591) for Gulf region and Red Wethersfield for central and upper district.

Black mold (*Macrosporium Porri*) is a disease which spreads rapidly over the field, especially late in the season. Some good may be done by spraying with bordeaux mixture, but its application is limited almost to the diseased portion.

Another disease attacking onions is smut (*Urocystis cepulæ*). The name of this fungus describes it fairly well. About all that can be done is to subject the field to rotation, and to sow seed from smut-free districts. Some years nearly all southern-grown onions brought to market will be more or less infected.

Rotting is especially severe in wet seasons when the crop cannot be properly handled, and is caused by a number of fungi. The best preventive is to store in a dry place, and consume as soon as practicable.

Onion fly, or onion maggot, is one of the most severe pests when it enters the field. There seems to be but little encouragement in combating the pest. It often leaves the field as mysteriously as it appeared. This disappearance has been coincident with the application of some supposed remedy, and has consequently led to the recommending of unreliable remedies. A thorough application of ground tobacco stems down the row seems to act as an insecticide and a repellent, besides being of value as a fertilizer.

Thrips attack the leaves at times, and become so numerous as to cause the tips to turn brown and finally destroy the whole leaf. Besides the insect injury they open the way for such fungi as Macrosporium. This insect may be treated successfully with kerosene emulsion, tobacco decoction, resin wash and possibly with kerosene-water mixture. P. H. Rolfs.

ONION, SEA: *Urginea maritima;* also applied to *Ornithogalum caudatum.*

ONÓBRYCHIS (Greek, *asses' food*). *Leguminòsæ.* Among cultivated plants, this genus contributes the sainfoin, used for forage. The group yields little in the way of ornamentals.

Perennial, sometimes shrubby and spiny: lvs. odd-pinnate, with entire not stipellate lfts.: fls. purplish, rose-colored or whitish, in axillary peduncled spikes or racemes; calyx-lobes subulate, for the most part nearly equal; corolla papilionaceous, the standard obovate or obcordate and narrowed toward the base; wings short; keel obtuse, equaling or exceeding the standard; stamens 9 and 1; ovary 1–2-ovuled: pod sessile, flat and hard, 1-seeded and indehiscent.—Species 80 and more, Eu., N. Afr. and W. Asia. Closely related to Hedysarum, but differing in the 1-seeded or 1-jointed pod.

viciæfòlia, Scop. (*O. satìva,* Lam. *Hedýsarum Onóbrychis,* Neck.). Sainfoin or Saintfoin. Holy Clover. Esparcet. Perennial herb with ascending sts. 1–2 ft. long: lfts. many, oblong, somewhat downy or pubescent beneath and glabrous above: peduncle exceeding the lf., the spike lengthening; fls. pale pink (varying to white): pod twice exceeding the lf., strongly curved on the lower edge, with short teeth on the margin and sometimes prickly. Cent. and S. Eu., Temp. Asia.—Grown for forage. It requires a limestone soil, and in the U. S. is grown chiefly in the southern states, but it has never become agriculturally important in this country. The seeds are nutritious and are eaten by fowls. From 100–150 lbs. of seed are sown to the acre. L. H. B.†

ONOCLÈA (Greek, *closed vessel;* alluding to the closely rolled sporophylls). *Polypodiàceæ.* A small group of coarse ferns of north temperate regions, with creeping rootstocks, anastomosing veins and two sorts of lvs., the segms. of the sporophylls being closely rolled about the sporangia into bead-like bodies. For *O. Struthiopteris,* see *Matteuccia.*

Onocleas are tenacious of life, and will grow under almost any conditions, especially *O. sensibilis,* but they prefer a moist, rather heavy loam, in a cool but not necessarily shaded position. *O. Struthiopteris* (a Matteuccia) in the sunny border is likely to burn during severe drought. It is a suitable deciduous fern for the greenhouse, and may easily be had in foliage before their natural season. (F. W. Barclay.)

sensíbilis, Linn. Sensitive-Fern. Fig. 2592. A coarse, easily grown fern, a native species, with broad triangular lvs., growing in low, wet places. Sensitive only in that it does not stand frost.
L. M. Underwood.

ONÒNIS (old Greek name). *Leguminòsæ.* Rest-Harrow. Good plants for borders and rock-gardens, with clover-like leaves.

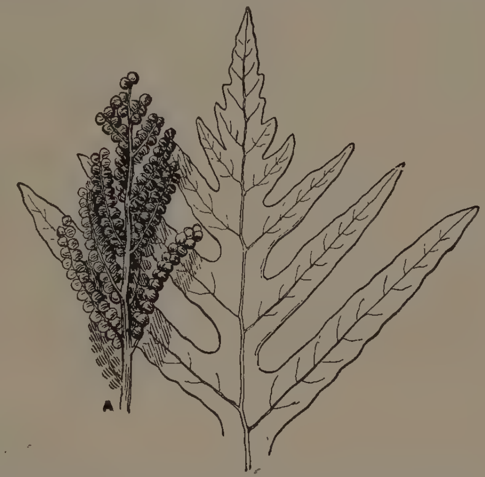
Annual, biennial or perennial, often shrubby; glabrous or villous: lvs. usually pinnately foliolate, the stipules attached to the petiole: fls. papilionaceous, yellow, purple, pink or rarely white, solitary, 2–3 in the axils or in peduncled racemes; calyx bell-shaped, 5-parted, deeply cut, narrow; standard large, striped; stamens united in a tube, the members sometimes partly free: pod usually swollen, few-seeded.—Some 70 species, Canaries, Medit. region, to Cent. and N. Eu. A few of the perennial species are more or less in cult. They thrive under usual treatment; prop. by division and by seeds. Sometimes the lvs. are 1-foliolate.

a. *Fls. solitary or in groups of 2–3, rose-colored.*

rotundifòlia, Linn. A neat, attractive, shrubby, hardy plant 1½ ft. high: lvs. trifoliolate; lfts. subrotund to ovate, serrate: peduncles axillary; racemes 2–3-fld.; fls. pea-like, bright rose, not bracted; standard striped with lines of a deeper shade. S. Eu. B.M. 335. G.L. 27:131.—Of easy cult. in border and rockery, not liking too much shade. Summer.

hircìna, Jacq. (*O. altíssima,* Lam.). Erect, spineless, more or less villous, 1–2 ft.: lfts. 3, oblong-lanceolate, acute, serrate: fls. about 2 together, rose and white, May–July or Aug. Eu.—A pretty plant for rather dryish borders and rocky places.

spinòsa, Linn. Somewhat shrubby, spinose, the sts. more or less erect: lfts. 3, oblong with cuneate base, subentire: fls. solitary, rose-colored. Eu.



2592. Sensitive fern.—Onoclea sensibilis. Fruiting frond at *A*.

fruticòsa, Linn. Sturdy compact little woody bush about 1 ft. high and becoming much broader: lfts. 3, to 1½ in. long, lanceolate and deeply serrate: peduncles about 3-fld. and collected into racemes or clusters; standard pale rose with central stripe, wings whitish suffused pink. Eu. B.M. 317. L.B.C. 16:1569. G.C. III. 47:420.—Excellent for rock-garden.

aa. *Fls. solitary, yellow.*

Nàtrix, Linn. Goat-Root. Yellow-flowered Rest-Harrow. Low, much-branched perennial: st. 1–1½ ft. high: lvs. trifoliolate; lfts. elliptical or oblong, serrated near the apex or sometimes entire; stipules large: fls. axillary, the standard finely striped with red. Midsummer to fall. B.M. 329. M. B. Coulston.
L. H. B.†

ONOPÓRDON (old Greek name). Sometimes written *Onopórdum. Compósitæ.* Coarse woolly Old World herbs.

Stems stout (sometimes acaulescent), winged by the decurrent bases of the lvs., which are large, alternate, prickly, dentate or pinnately cut: involucre globose, the bracts imbricated in many series, and in some cases spiny; receptacle flat, fleshy, honeycombed, not bristly; pappus not plumose, but with bristles in several series. —About 12 species, annual and biennial.

a. *Involucral bracts erect and appressed.*

b. *Sts. usually nearly simple, the heads often solitary.*

arábicum, Linn. St. tall, swollen and deeply winged by the decurrent lvs.: branches numerous, short, erect: lvs. ovate-lanceolate, sinuate and spiny: fls. in dense, solitary terminal heads, the infl. usually arachnose, as are the erect involucral bracts. Medit. region. B.M. 3299.—A showy biennial with purplish red fls.

BB. *Sts. mostly much branched, the heads corymbose or paniculate* (*solitary at the end of the peduncles in O. Acanthium*).

Acánthium, Linn. Scotch Thistle. Biennial, vigorous, much-branched, 3–9 ft. high: lvs. oblong, lobed and dentate, acute, the lower often 1 ft. long, cottony white, spiny: heads of pale purple fls. 1½–2 in. across, borne singly on the branches. July–Sept. B.B. 3:491. Gn. 46, p. 9; 68, p. 157. G.W. 7, p. 425. R.B. 20, p. 200.—The Scotch thistle is often called the cotton thistle; sometimes also Argentine, asses', down, oat, Queen Mary's or silver thistle. It is apparently not advertised in Amer., but is sometimes cult. for "auld lang syne," and occasionally it is used with striking effect by some lover of hardy plants. It is then placed against a background of dark shrubbery, which sets off the silvery foliage and bold habit. The plant is rarely found growing wild in the Atlantic States, having come from Eu. The Scotch thistle will probably never be a weed of the first importance in Amer., as is the Canada thistle. Nevertheless, care should be taken not to let it go to seed. A white-fld. Scotch thistle, var. **álba,** Hort., was advertised in Germany in 1894 as a horticultural novelty. Gt. 45, p. 107.

taùricum, Willd. An ornamental plant of tall stately growth and many-headed infl.: st. white-hairy: lvs. somewhat decurrent, elliptic-oblong, the margins wavy and spinose; involucral bracts ovate-lanceolate, the tips subulate. Russia and S. Eu. G.W. 7, p. 425.—Perfectly hardy and only recently intro.

polycéphalum, Boiss. A densely tomentose, tall-stemmed biennial with grooved sts. and a many-headed corymb of showy fls.: lvs. somewhat lobed, spiny-margined, diminishing in the infl.: involucral bracts pale, all erect, lanceolate.

AA. *Involucral bracts* (*outer*) *recurved.*

bracteàtum, Boiss. & Heldr. A tall tomentose much-branched biennial: lower lvs. oblong-lanceolate, the shallow lobes and often the margins tipped with yellow stout spines; cauline lvs. much smaller, decurrent, diminishing in the infl. to start short bracts: heads large, globose, the outside involucral bracts recurved. E. Medit. region.—Probably not hardy northward.

O. Sàlteri, Hort. "Plant pyramidal in habit, about 5 ft. high, silvery shining. Lowest lvs. widely spreading on the ground, incised, spiny, upper reduced." Country unknown.

N. Taylor.†

ONÓSERIS (*asses' salad;* significance not evident). Including *Isótypus. Compósitæ.* Some twenty herbs or shrubs, mostly Andean, but also in Mexico and southeastern Brazil, grown rarely indoors and out for the large purple, pinkish or white flower-heads; allied to Mutisia, but it has no close relatives of much horticultural importance.

Plants of various habit, mostly erect, sometimes annual, some species almost stemless: lvs. radical and cauline, white-tomentose beneath: heads large, heterogamous, solitary or panicled, the peduncles or scapes usually long and more or less bracted; ray-florets pistillate in one series (heads discoid in *O. Isotypus*); disk-florets usually hermaphrodite and fertile; involucre hemispherical or top-shaped, the bracts linear, imbricate and in many series, the exterior ones gradually shorter.—They appear to require no special cult. treatment; prop. by seeds.

O. adpréssa, Less. (Centroclinium adpressum, Hook.). Little shrub, blooming under cult. at 1 and 2 ft., with woolly branches: lvs. lanceolate, reflexed, 3 in. or more long, nearly entire but undulate: peduncle solitary and terminal or becoming lateral by elongation of other shoots; head solitary, large, fragrant; rays long and narrow, about 8, rose-purple. Peru. B.M. 3115.—*O. Drakeàna,* André. Woody, little branched, often weak: lvs. alternate, ovate, lanceolate or hastate, entire or shallowly dentate: peduncles scape-like, 1-headed, with few bracts; rays violet, about 20, showy. Colombia. R.H. 1883:180.—*O. Isótypus,* Benth. & Hook. (Isotypus onoseroides, HBK. Caloseris rupestris, Benth.). Showy shrub 3–5 ft. high, the branches white-lanate: lvs. long-petioled, large, broadly hastate-cordate, 5–8 in. long, acute, sinuate-lobed and dentate, 3–5-nerved, the petioles 6–10 in. long: heads about 1 in. long in a terminal panicle, the corolla red and scarcely exceeding the involucre. S. Mex. Guatemala. G.W. 12, p. 11.—*O. purpuràta,* Willd. Nearly stemless perennial: lvs. radical, lyrate, the terminal lobe large and deltoid-hastate and dentate: scape branched at middle, 3-headed, the rays purple and short. Colombia.—*O. refléxa,* Less. (Centroclinium reflexum, Hook.). Woolly branched, about 2 ft., probably annual: lvs. ovate-lanceolate, 2–3 in. long, coarsely toothed and acute: peduncle solitary, terminal or from upper axils, with many small bracts: heads large and handsome, fragrant; rays 9–12, very narrow, rose-purple. Peru. B.M. 3114.

L. H. B.

ONÓSMA (*onos,* an ass, and *osme,* smell; the odor reputed to be liked by that animal). Golden Drop. *Boraginàceæ.* Outdoor or border plants, grown for the small pretty flowers.

Bristly hardy perennial, annual and biennial herbs or undershrubs, with long narrow alternate lvs. and 1-sided simple or cymose bracted racemes: fls. yellow, purple, or white, tube-like, or urn-shaped, sessile or with short pedicel, with 5 very short corolla-lobes; calyx 5-parted or cut; corolla-throat dilated or contracted; stamens 5, inserted midway on corolla-tube, mostly included; ovary with 4 distinct lobes, the style filiform and stigma small: nutlets 4 or fewer, erect or incurved, smooth and shining or less frequently tuberculate.—Species 70, Medit. region and the Himalayas. They are adapted to borders and rock-gardens; of simple cult. requirements. The perennial kinds are increased by cuttings in summer, in a frame; the annuals and biennials by seeds. Most of the cult. species do not ordinarily much exceed 1 ft. in height and many of them are lower than that.

echioìdes, Linn. Biennial or perennial strigose herb, from a red root, blooming in spring, erect or rarely branched, 6–9 in. high or more: lvs. spatulate or linear-lanceolate, sessile, becoming cordate above; floral lvs. lanceolate to nearly ovate-lanceolate: fls. pale yellow to whitish, drooping, fragrant; corolla cylindrical or subclavate. S. Eu. G.W. 6, p. 529.

stellulàtum, Waldst. & Kit. Perennial, branched at base, ascending, hispid: lvs. linear-oblong, plane, obtuse or the upper ones acute: fls. yellow, more or less cernuus, short-pedicelled, in bifid cymes; corolla 1 in. long and about ½in. wide at apex, somewhat clavate, twice longer than calyx, the teeth very short and revolute. S. and S. E. Eu. Variable; cult. chiefly in the var. **taùricum,** Hort. (*O. taùricum,* Pall. *O. angustifòlium,* Lehm.), with narrow revolute lvs. and citron-yellow fls., the corolla often 1½ in. long. B.M. 889. J.H. III. 35:11. Gn. 50, p. 251. G.C. II. 16:21; III. 51:274. G. 4:447. Succeeds well on high ground or on sunny rockery, with light, open, deep soil. Prop. by cuttings generally, or by seed.—Var. **compáctum,** Hort., is a condensed form. M.D.G. 1912:325. *O. helvéticum,* Boiss, is a Swiss form, not so tall and with rather broad lvs. G.C. III. 52:280.

álbo-ròseum, Fisch. & Mey. (*O. álbum,* Hort.). Perennial, more or less woody, tomentose: lvs. hoary, oblong and somewhat obtuse, narrowed to petioles, the upper ones sessile and lance-oblong: fls. white changing to rose and violet, velvety; corolla nearly 1 in. long, clavate pubescent, nearly double length of calyx. Asia Minor.

Fórrestii, W. W. Smith. Perennial: basal lvs. linear-lanceolate or -oblanceolate, 6 in. or less long, the st.-lvs. linear and erect, all of them white-tomentose: infl. rather dense, thickly covered with whitish hairs, the fls. rose-color; calyx nearly ½in. long, the narrow-tubular canescent corolla scarcely exceeding it. Yunnan, China.

O. sericeum, Willd. Perennial, somewhat woody, silky-pubescent: lvs. oblong-lanceolate to obovate, the lower ones narrowed to the petiole: fls. yellow, ¾in. long, the corolla broad at apex and exceeding the calyx. Orient. G.C. III. 52:281.—*O. Thómpsonii*, Hort., is Echium rubrum, Jacq., of S. Eu. and Caucasus: lvs. white tomentose, linear-lanceolate: fls. scarlet, racemose.

L. H. B.†

ONOSMÒDIUM (like *Onosma*, a European genus of this family). *Boraginàceæ.* False Gromwell. About 10 species of N. American and Mexican branching herbs, mostly or wholly perennial, bristly, 1–4 ft. high, rarely transferred to cult. grounds: lvs. oblong, sessile, rib-veined: fls. white, greenish or yellowish, in long, erect, leafy, raceme-like clusters; corolla tubular or oblong-funnel-shaped, with throat naked, the lobes erect, acute, the sinuses more or less inflexed; style filiform or capillary, very long; stigma exserted before the corolla opens: nutlets ovoid or globular, bony, smooth and polished, white. Closely related to Lithospermum. None of the species seems now to be in the trade; the names and descriptions may be found in the manuals of native plants. They are of little value horticulturally.

ONTADÈNIA: *Odontadenia.*

ONÝCHIUM (Greek, *onyx*, a claw; referring to the shape of the lobes of the lvs.). *Polypodiàceæ.* A group of small mainly Asiatic ferns, with the sori arranged on a continuous linear receptacle as in Pteris, but with narrow segms. in which the indusia extend nearly to the midrib. For cult., see *Fern.* The orchids occasionally advertised as onychiums are dendrobiums.

auràtum, Kaulf. Lvs. ovate, a foot or more long by half as wide, quadripinnatifid, with membranous indusia and abundant sporangia of a golden color; divisions of the sporophylls pod-like. India and adjacent islands.

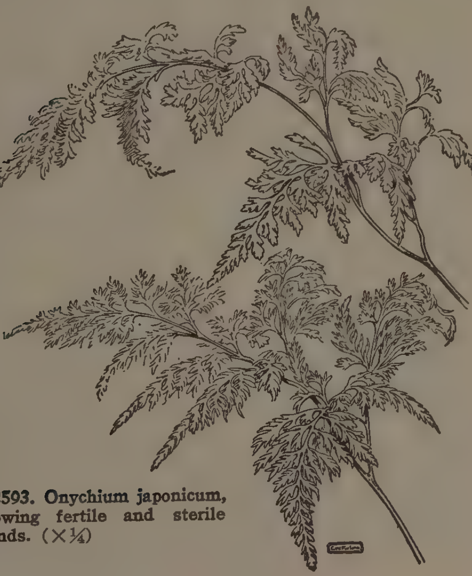
japónicum, Kunze. Fig. 2593. Lvs. ovate, a foot or more long by half as wide, quadripinnatifid, with pale indusia and brown sori; divisions of the sporophylls linear-mucronate, similar to those of the sterile lf. India, China, and Japan.

L. M. Underwood.

OPHÈLIA: *Swertia.*

OPHIÁNTHE: *Gesneria.*

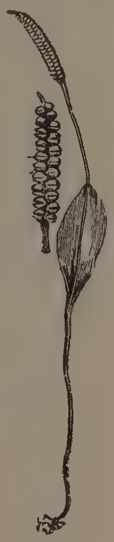
OPHIOGLÓSSUM (Greek, *serpent's tongue*). *Ophioglossàceæ.* About 40 species of small plants allied to true ferns, of wide distribution. The sts. are subterranean, small, bearing usually a single erect succulent lf. which consists of a petiole, an expanded simple blade, and a contracted fertile spike bearing 2 rows of fleshy coalescent sporangia; venation reticulate. Rather difficult of cult., and mainly of interest as curiosities.



2593. Onychium japonicum, showing fertile and sterile fronds. (×¼)

vulgàtum, Linn. Adder's Tongue Fern. Fig. 2594. Lf. 6–12 in. high, the petiole 3–6 in. high, the blade ovate, 1–2 in. long, the spike about 1 in. long, on a long stalk. Spores mature in July. In low places, Eu. and N. Amer.—May be cult. in moist peat in a partially shaded spot. Occasionally found in large numbers in peaty meadows.

R. C. Benedict.



2594. Ophioglossum vulgatum.—Adder's tongue.

OPHIOPÒGON (Greek, *snake's beard;* a translation of the Japanese name). *Liliàceæ.* Herbs, grown for the bluish or white small flowers and the grass-like foliage that may form a good ground-cover.

The genus is oriental, of about a score of species. The plants have a short thick rhizome, and the fibrous roots sometimes act like runners, and may be thickened into tubers: lvs. linear or oblong-lanceolate and narrowed into a petiole: bracts small, scarious: perianth-tube none; stamens 6, fixed at the base of the segms.; filaments erect, distinct, shorter than the linear anthers; cells of 3-celled ovary 2-ovuled: fr. indehiscent; seeds in the form of a globose berry.—The E. Indian species appear not to be cult. The genus is closely allied to Liriope. *O. spicatus*=*Liriope graminifolia.*

Of this genus, two species are well known in cultivation. They are low-growing herbaceous perennials from Japan, with linear foliage, which is often striped or spotted with white or yellow, and racemes of small six-parted pendulous flowers, varying from white through lilac to violet-purple. They are procurable from a few dealers in hardy perennials, from specialists in Japanese plants and from Dutch bulb-growers. The most popular form is *O. Jaburan* var. *aureus variegatus*, which is chiefly used as a greenhouse foliage plant. The flowers of *O. Jaburan* are followed by large showy shining dark blue berries. It is easy to manage in the window, and is almost hardy. *O. japonicus* is much used in Italy and southern France for a green turf and for border edgings, and it begins to be used for the same purpose in southern California. It needs no clipping, and will stand under the shade of trees, making a dark green lawn-cover, standing well in drought. The species of ophiopogon are propagated by division.

japónicus, Ker. Perennial stemless glabrous herb, with a stoloniferous rhizome: fibrous roots long, slender, often nodulose: root-lvs. numerous, erect, narrowly linear, ½–1 ft., and 1–1½ lines wide, 5–7-nerved: scape 2–4 in. long; raceme lax, few-fld., 2–3 in. long, the lower fls. in groups of 2–3; fls. drooping, violet-purple to lilac or more or less whitish. Japan, Korea, N. China. B.M. 1063. Var. **variegàtus,** Hort., has variegated foliage.

Jabùran, Lodd. Habit of the above, but more robust: lvs. 1½–3 ft. long, 4–6 lines wide, many-nerved: scape ½–2 ft. long; raceme 3–6 in. long, the lower fls. usually in groups of 6–9; fls. white to lilac. Japan. L.B.C. 19:1876 (a fine pure white). Var. **cærùleus,** Hort., has "blue" fls. Var. **aùreus variegàtus** has foliage striped golden yellow. Var. **argénteus variegàtus** has foliage spotted white. Var. **argénteus vittàtus** has foliage striped white.

Regnièri, Bois. Stemless: lvs. in a rosette, erect or reflexed, lanceolate, slender-petioled, to 1 ft. long, marked with pale green and yellow: scape 8 in., 2-edged, bearing a several-fld. raceme; fls. violet-white, to

¾in. across, the tips of the segms. greenish. Cochin-China. R.H. 1906, p. 371.—Recent.

Wilhelm Miller.
L. H. B.†

ÒPHRYS (Greek, *eyebrow*). *Orchidàceæ*. Terrestrial orchids.

Having the habit of Goodyera, bearing a basal rosette of lvs. with an erect fl.-st. terminating in a raceme or spike of fls.: sepals similar, spreading; petals smaller, often pubescent; labellum generally convex with incurved margins, not spurred, entire or 3-lobed; column short.—About 30 species, mostly in the North Temperate Zone in Eu., Asia and N. Afr., the greater number being found in the Medit. region. Cult. as for habenaria.

A. *Margin of the labellum brown or purple-brown.*

B. *Labellum scarcely longer than the sepal.*

C. *Sepals green.*

aranífera, Huds. Spider Orchis. Resembles *O. apifera*. Sepals green; petals very short; labellum dull brown, marked with paler spots, obscurely lobed. Spring and early summer. Eu. B.M. 5712. B.R. 1197.

fúsca, Link. Lvs. oblong-lanceolate, those on the st. narrower: sepals green, ovate-oblong, the upper one smaller, oblong; petals half as long, lanceolate-obtuse; labellum oblong, dark purple and hairy on the margin, disk light blue, polished. Medit. region. B.R. 1071.

CC. *Sepals rose-colored or white.*

arachnìtes, Lam. St. erect, leafy: lvs. ovate-lanceolate: fls. distant; sepals ovate concave, rose-colored, tinged with green; petals conical, fleshy, smaller than the sepals and colored like them; labellum round, with the sides reflexed, black-purple, with yellow marks and green appendages. Cent. Eu. B.M. 2516. G.C. III. 48:482.

apífera, Huds. (*O. arachnìtes*, Reichard). Bee Orchis. St. 9–18 in. high, with few oblong or lanceolate lvs.: fls. 3–6, rather large; sepals ovate, pale pink or white; petals smaller, erect; labellum broad, convex, lobes all turned, velvety brown, marked with paler lines or spots. Fls. early summer. Dry pastures, Cent. and S. Eu. Gn. 69, p. 257. G. 35:379.

BB. *Labellum longer than the sepals.*

Spéculum, Link. Looking-Glass Orchis. St. 4–12 in. high, 3–6-fld.: lvs. linear-oblong: fls. ½–1 in. across; sepals linear-oblong, green, with purple bands; petals very small, triangular-lanceolate, dark purple-brown; labellum quadrate, oblong, very convex; disk shining blue, with a yellow edge; margin pilose and fimbriate, maroon-purple. Medit. region. B.M. 5844. B.R. 370.

muscífera, Huds. (*O. myòdes*, Jacq.). Fly Orchis. St. very slender, 3–4-fld.: sepals oblong or narrowly ovate, greenish; petals narrowly linear; labellum long, oblong, purplish brown, with pale white or blue marks in the center; central lobe notched. Spring and early summer. Cent. and E. Eu. R.B. 21:241.

AA. *Margin of the labellum yellow or greenish yellow.*

tenthredinífera, Willd. Sawfly Orchis. St. 6 in. high: lvs. elliptic-lanceolate: spike 3–8-fld.; fls. nearly 1 in. across; sepals oblong, obtuse, concave, varying from rose to white; petals very small; labellum broadly obcordate, greenish yellow, pubescent, with a large chestnut-colored spot on the disk. Medit. region. B.R. 205; 1093. B.M. 1930. F. 1872, p. 128.

lùtea, Cav. St. 4–7 in. tall, many-fld.: lvs. linear-oblong: fls. ¾in. across; sepals oblong, obtuse, incurved, green; petals much smaller, linear-oblong; labellum quadrate, golden yellow, with a purple disk. Medit. region. B.M. 5941.

Áceras anthropóphora, Br. Advertised as Ophrys anthropophora, Linn. Man Orchis. St. about 9 in. high, the spike being 2–4 in. long: lvs. ovate to oblong or lanceolate: fls. dull yellowish green; sepals and petals converging over the column; labellum much longer than the sepals; side lobes long, narrow, and the middle lobe split into 2 narrow lobes. Early summer. Pastures, S. Eu. Ophrys differs from Aceras in having a very convex labellum. Both genera are distinguished from Orchis by the absence of a spur.—*O. etrúsca*, Hort., and *O. Grampínii*, Hort., are hybrids between O. aranifera and O. tenthredinifera.

The name Ophrys is used by some botanists to replace Listera (p. 1891); in that case, the synonymy of the listeras becomes:

O. convallarioìdes, Wight (Listera convallarioides, Torr.).—*O. cordàta*, Linn. (Listera cordata, R. Br.).—*O. Smállii*, House (Listera Smallii, Wiegand). Similar to O. convallarioides: lvs. ovate-reniform, borne at or below the middle of the st.: raceme loose, few-fld., lip ¼in. long, not ciliate, broadly ovate, cleft at the apex; ovary glabrous. Mountains of Pa. to N. C.

Heinrich Hasselbring.

OPHTHALMOBLÁPTON (Greek, *eye injuring*, from its poisonous action). *Euphorbiàceæ*. Trees with milky juice: lvs. alternate, simple, pinnately veined: infl. axillary or lateral; fls. inconspicuous, monœcious, apetalous; calyx with 1–3 short lobes, valvate in the bud; stamen 1; styles connate to the apex; ovary 3-celled, 3-ovuled.—Three Brazilian species related to Sapium and Stillingia, not cult. but noted for their poisonous action upon the skin and mucous membrane. *O. macrophýllum*, Fr. Allem., Saint Lucia, is the best known species.

J. B. S. Norton.

2595. Oplismenus hirtellus.

OPIUM is the product of *Papaver somniferum*, the common annual summer-blooming poppy of gardens with smooth, glaucous leaves and white flowers.

OPLÍSMENUS (Greek, *awned*, referring to the awns). *Gramíneæ*. Delicate creeping, branching grasses with rather broad blades and narrow panicles consisting of spreading 1-sided racemes: spikelet 1-fld.; first and second glume and often the sterile lemma awned.—A genus allied to Panicum, containing 5 or 6 species of the warmer regions, one of which is cult. in conservatories for ornament.

hirtéllus, Roem. & Schult. (*Pánicum variegàtum* of florists). Fig. 2595. A half-creeping perennial, with small, greenish panicles, the common form with neatly white- and pink-striped lvs. W. Indies. Gn. 47, p. 68. G. 37:271.—Popular for edges of beds and for hanging-baskets. Prop. by divisions of the rooting sts. This plant has usually passed as *O. Burmannii*, which, however, is an annual with silky panicles.

A. S. Hitchcock.

OPORÁNTHUS: *Sternbergia*.

OPÚNTIA (old Latin name used by Pliny, later used for the Indian fig, probably derived from Opus, a town in Greece). *Cactàceæ*. Succulent plants, a few species of which are extensively cultivated in warm regions for their large, edible fruits, while others are grown as hedges; numbers of species are grown in the collections of fanciers for their oddity.

Opuntias vary from small, prostrate plants a few inches above the ground to trees with spreading tops 20 or more ft. high: sts. flat, clavate or cylindrical, bearing more or less elevated areoles; from each of which appears a small caducous pointed lf., rarely spreading and foliar; an oval or circular area, more or less covered with soft wool, intermixed with barbed bristles and usually a variable number of spines, occurs in the axil of each lf.: fls. borne singly toward the upper part of the joints or sts., on the bristle-bearing part of the areole, and with spreading, showy corollas; the usually many-ovuled inferior ovaries are not of foliar development, and sometimes differ but slightly in appearance from normal sts., usually bristle- and spine-bearing: fr. dry or succulent, frequently edible; seeds large, flattened, discoid and often margined.—There are about 130 species and many varieties and hybrids, extending from Canada southward through the U. S., Mex., W. Indies and Cent. Amer. to the southern part of S. Amer. The species are confined mostly to arid and semi-arid regions; however, some are found in regions of heavy rainfall. They are found in greatest quantity and variety of species in S. W. U. S. and N. Mex., where they are often trees and form the most conspicuous part of the flora. Opuntia is a genus of great variation in habit and appearance, and, from the frequency of natural hybrids and ill-defined specific lines, one of the most difficult genera of flowering plants to present satisfactorily in systematic order. Some of the largest cacti are opuntias, while nearly all that are of economic value belong to this genus.

Although the opuntias are less attractive as pot-plants and, on account of their barbed spines and bristles, more difficult to handle than most other cacti, they are coming into favor on account of their unique appearance, rapidity of growth and attractive flowers. They grow best with an abundance of heat and sunlight, the character of the soil being a secondary consideration. Like all other cacti, they require perfect drainage. They are readily grown from cuttings, and also from seed under proper management.

Economically considered, the opuntias are by far the most important of the cacti. Although originally confined to the New World, the more important species are now in cultivation or have escaped from cultivation and become wild in every arid and semi-arid region of the globe where the temperature permits their being grown. Wherever grown, their tendency is to escape from cultivation and become persistent and troublesome weeds. In this respect they are much more to be dreaded in foreign countries than in America, the place of their nativity.

As ornamental plants, opuntias are unusual rather than pleasing. From their stiff, formal aspect they do not harmonize, as a rule, with other plants, and on account of their spines and bristles they are difficult to handle and are considered by most gardeners as a nuisance in decorative planting. It is as hedges and as groups of mixed species that they are most effective. Most species grow rapidly and bloom profusely. The flowers, as a rule, are large and showy and of various colors, although yellow predominates. They wither soon after opening and remain at their best only for a few days. The spines and bristles which usually cover the base of the flowers render them of no value as cut-flowers. With many species, such as *O. leptocaulis, O. tetracantha,* and some forms of *O. Tuna,* the bright-colored fruits, which remain on the plants for a long time after ripening, render them more attractive in fruit than in flower. Crested or fasciate forms (Fig. 2596) are common.

Although extensively cultivated for their fruit in many countries, where they furnish an important article of diet for four to five months each year, they do not as yet take a pomological rank with the horticulturist, although they are much more widely used and of far more economic importance than many plants which have an established place in pomological literature. From the fact that opuntias flourish best in regions where experimental horticulture receives little or no attention, the development of desirable economic varieties has not been what might be expected of plants which respond so readily to cultivation and selection, and which may be hybridized with so little difficulty. Botanically considered, the fruit is a kind of berry, varying from dry to fleshy and succulent. Morphologically, it is a modified stem with the true seed-capsule sunken into its apex; hence it bears leaves and spines, and usually, under suitable conditions, and frequently in the natural state when it becomes detached, will bud and grow like a normal stem-cutting.

Opuntias were cultivated by the aborigines of America at the time of its discovery, and were early taken by the Spanish explorers to Spain and Spanish colonies in other parts of the world. After becoming established in the Canaries, Azores, and Madeira islands, it was not long before their culture extended to Portugal, Spain, and the whole littoral region of the Mediterranean. From there they spread to Egypt, India, and other parts of southern Asia. In comparatively later times they reached South Africa, Australia, and New South Wales, where they are fast becoming a serious menace to agriculture and grazing. In all the regions above noted they have escaped from cultivation and have become pestiferous weeds.

The want of fixed characters, the great variations in most species under different soil and climatic conditions, and the readiness with which natural hybrids occur, make the identification of cultivated and introduced species so difficult that the considerable literature on this subject is extremely uncertain as to nomenclature. The common names Indian fig, barberry fig, prickly pear, and tuna, are applied indiscriminately by most persons to any flat-jointed opuntias, but more particularly to the kinds with edible fruits.

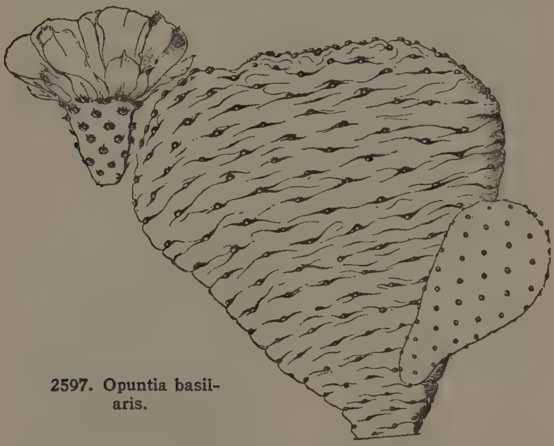
2596. Opuntia ramosissima. To illustrate fasciation, which is of frequent occurrence in nearly all species of cacti.

The two most widely distributed and extensively cultivated are *O. Ficus-indica* and *O. Tuna.* These plants have often been confused by authors. Much that has been written under the name of one species really applies to the other. They are closely linked together by hybrids, and each has been in cultivation for so long a period that numerous cultural varieties have developed, particularly in Mexico and Sicily. It is possible that the many cultivated forms of both species originated from the same source.

Although the Mexicans and Indians eat the fruit of more than a score of indigenous species, the two named above, with their many cultivated forms, are by far the most desirable and palatable. *O. Ficus-indica* is preferable in most respects to *O. Tuna* on account of its fewer and smaller spines and usually larger fruit. The latter, however, makes a more formidable hedge, and is more frequently planted in the United States. Hedges of this plant are to be seen at many of the old Spanish missions in Arizona and California, where they were probably first introduced into the United States. *O. Ficus-indica* is frequently grown by the Mexican population of New Mexico, Arizona, and California. In southern Florida it has escaped from cultivation and become naturalized. The fruits are usually larger and fewer-seeded than in *O. Tuna*, and are commonly yellow. They frequently measure 3 to 4 inches in length and 2 to 3 inches in width. Forms of this species about the old missions of southern California vary considerably. One form, known as *Tuna Colorado*, has an insipid, light crimson-colored fruit, while another, *Tuna manse*, has a yellowish fruit, irregularly mottled with crimson.

General cultivation. (D. M. Andrews.)

Hardy opuntias satisfy a rather general desire for something unique or grotesque, while at the same time they possess enough ornamental value to recommend them to everyone, and especially to those lovers of cactaceous and succulent plants whose space indoors is limited. Being natives of the western plains and foothills of the mountains, they can scarcely suffer from long-continued drought, and the sunny side of the rockery will suit them exactly, as it will allow all surplus moisture to drain off, and no artificial watering will be necessary. William Falconer, who has used large quantities at Schenley Park, Pittsburgh, Pennsylvania, writes as follows: "In certain localities, as on bleak, exposed banks and about rocky knolls, opuntias and *Yucca angustifolia* can be used unsparingly with perfect success." He also says, "All have been planted out-of-doors, remaining unprotected summer and winter, and all have been perfectly hardy." They have succeeded also at Kew Gardens, in the very humid climate of England, without protection. Their requirements seem to be as follows: a porous, well-drained soil, a sunny exposure, and a season long enough in which to ripen the fruit and annual growth; these conditions being complied with, they will endure almost any degrees of cold to be experienced even in the most northern portions of the United States. Their altitude-limit in Colorado indicates that they will succeed as far north as Indian corn can be matured. The following kinds have been used successfully, as above indicated: *O. arenaria*, with small, round to oblong, very spiny joints, the spines varying much in color from gray and straw-color to purplish brown; *O. arborescens*, the tree or candelabrum cactus, the tallest of this list, is of cylindrical branching growth, with bright purple flowers and yellow fruit; *O. Camanchica* has very large, orbicular joints, the upper half thickly beset with spines, fruit purple; *O. fragilis* resembles *O. arenaria*, but is smaller; *O. humifusa* includes a multitude of forms, all of which are very hardy; *O. phæacantha* var. *major* is one of the most striking sorts, with immense, glaucous joints, dark purple spines, yellow flowers, and purple fruit; *O. polyacantha* is one of the most variable, as well as one of the most showy. The spines vary from ivory-white to purple and brown, and from short and stout to long and slender. Nearly all the opuntias have very showy flowers, usually in various shades of yellow and orange.



2597. Opuntia basilaris.

Economic value and cultivation.

Two opuntias, *O. Ficus-indica* and *O. Tuna*, and possibly a few other closely allied ones, are extensively grown in Mexico. The fruit begins to ripen in June and July, while the later varieties last until December. The fruit is consumed by all classes and conditions of people. The fine bristles which invest the fruit are usually removed before picking by rubbing them with straw, grass or leaves. The fruit is later picked by the hand, or, in some instances, with wooden tongs. In large plantations, when the fruit is raised for commercial purposes, it is usually harvested with a heavy knife, the workman first cutting off the joint bearing the fruit, and later detaching the separate fruits.

In preparing the fruit for the table, a thin slice is cut from each end and a slit made through the paring, joining the cut surfaces. The thin paring is easily separated from the mealy but juicy pulp, and quickly removed with the fingers.

Today the finest opuntia fruits are grown in Sicily, where they are one of the most important crops that the island produces. From July to November the peasants live almost entirely on this fruit, and considerable quantities are yearly exported to other countries, some of which finds its way to New York and other American cities. It is grown extensively by the Arabs throughout northern Africa, and forms an important part of their food for a portion of each year.

The nutritive value of this fruit ranks high, as shown by the following analysis by Wolff:

	Per cent
Dry substance	21.60
Ligneous matter	3.70
Proteid substances	.59
Fatty bodies	1.80
Sugar	14.00

It has been ascertained that some of the best varieties are capable of producing on lean, sandy or rocky soil, ill-suited for growing ordinary crops, as much as 18,000 pounds of fruit to the acre. When it is considered that this is equal to 2,500 pounds of sugar, as well as other valuable food constituents, it may be readily seen that the food value from the standpoint of nutrition is considerable.

Plantations are usually made on dry slopes of hills, as the plants do not thrive where there is much moisture or on heavy clay soils. Joints, cut or broken from the plants, are used instead of seeds, and are planted at distances of 6 to 8 feet in furrows from 6 to 15 feet apart. No tillage is practised, as they grow rapidly, and in a few years shade and smother out all other growth. Before planting, the cuttings are exposed in half sunlight from seven to fifteen days, that they may partially wither, in order to facilitate rooting.

An important advantage in the culture of these plants is the regularity of the yearly crop. They begin to bear in about three years after planting, and continue in bearing for many years.

Of the opuntias indigenous to the United States, none as yet has been grown for fruit, or with an effort to improve them. *O. Engelmannii* has a large but poorly flavored fruit, rarely eaten, even by the Indians. *O. lævis* has one of the largest and most palatable fruits of any of the species found growing wild within the United States. This plant also has the advantage of having but few spines. *O. Camanchica*, *O. humifusa*, *O. chlorotica*, *O. phæacantha* and *O. macrocentra* have medium-sized fruits, insipid and unpalatable to the cultivated taste, but eaten by Indians and Mexicans.

Wherever grown extensively, the opuntia fruits are used for making a weak alcoholic drink. The juices of the highly colored sorts are sometimes used to color confectionery.

Many of the opuntias have considerable forage value, particularly during periods of long drought when other forage crops are short. The range cattle of the southwestern United States feed on either the branches or fruits, or both, of nearly all the indigenous species, the flat stems of *O. Engelmannii* and the pendulous fruit clusters of *O. fulgida* being most largely consumed. When cattle are fed largely on unsinged native opuntias, the spines and bristles do great injury. They collect mainly in the mouth, making eating very difficult if not impossible on this account. There are indications that "hairballs" composed of opuntia fibers and spicules are likely to be prevalent also under such conditions.

In northern Africa the flat joints of the forms with few spines are used as forage for cattle during the dry season, after being allowed to ferment slightly. In Tunis, plantations are sustained by dairymen for the purpose of feeding their cows upon the fleshy stems.

Species of opuntia have run wild to a remarkable extent in southern Africa. They have spread rapidly during the past century, and in many places have crowded out the grasses and become a nuisance. Two forms of the plant are recognized by the Dutch farmers; viz., a thorny variety growing on the open country and on stony hillsides known as Doornblad, and a fewer-spined larger variety with thicker stems known as Kaalblad. It is probable that these two varieties originated from the same introduction, for, according to Macdonald, the seed from the Doornblad or Kaalblad variety may give rise to plants resembling either or both of them. It is extensively used as feed for cattle, ostriches and pigs, either alone or when mixed with other forage. Here, however, much harm has come from range cattle eating it in times of little or no other forage, and ostriches become blind from the spines and bristles getting into their eyes in eating the fruits.

In New South Wales and Australia, where several species have escaped from cultivation and spread over large areas of arable land and driven out more valuable forage plants, the land has depreciated 50 per cent in value. Here, however, some of the worthless species, such as *O. vulgaris* and *O. monacantha*, are more widely spread than the more valuable varieties of *O. Ficus-indica* and *O. Tuna*.

From what has been said it may be seen, first, that varieties of *O. Ficus-indica* and *O. Tuna* produce large crops of edible and nutritious fruits; second, that plants with few or no spines are the general rule in *O. Ficus-indica* and of not infrequent occurrence in *O. Tuna;* third, that opuntias are strong, vigorous plants that will grow in situations in which few other plants will thrive; fourth, that spineless forms make valuable forage.

With these and more qualities to recommend them, it yet remains for horticultural enterprise to develop a spineless and bristleless variety that will not only be of value for forage but will produce large crops of fruits as attractive to the educated palate as to the savage. From the experience gained in establishing a garden of nearly seventy species and varieties of opuntias, comprising about 300 plants, and watching their growth and behavior for several years, it is thought that they offer great possibilities in the way of improvement in the hands of a careful plant-breeder.

In recent years, the prickly pear has attracted considerable attention as forage for cattle. Full report of yields of several species in test plantations in southern Texas is given in Bulletin No. 208 of the United States Department of Agriculture (May, 1915) by David Griffiths. See also a discussion of the forage value of prickly pears by Woodward, Turner and Griffiths, "Journal of Agricultural Research," August, 1915.

KEY TO THE SPECIES.

A. *Articulations or joints strikingly different, flat to cylindrical* .... 1. **brasiliensis**

AA. *Articulations or joints similar, more or less flattened (Nos. 2–32).*

B. *Species from S. Amer* .... 2. **galapageia**
3. **monacantha**
4. **aurantiaca**
5. **crinifera**

BB. *Species from N. Amer.*

C. *Joints pubescent* .... 6. **microdasys**
7. **basilaris**
8. **puberula**

CC. *Joints not pubescent (except sometimes in O. pycnantha).*

D. *Fr. fleshy or succulent.*

E. *Size of joints large: plants mostly large (O. crassa moderately small).*

F. *Color of spines white* ..... 9. **leucotricha**
10. **triacantha**
11. **candelabriformis**

FF. *Color of spines yellow (sometimes red to white in O. Engelmannii, O. polyantha, O. crassa, and O. Ficus-indica).*

G. *Spines none or few* .... 12. **crassa**
13. **Ficus-indica**

GG. *Spines always present, few to many. (One form of O. macrocentra has no spines, and occasional plants of O. chlorotica are without spines.)* ..... 14. **polyantha**
15. **Tuna**
16. **chlorotica**
17. **pycnantha**
18. **Engelmannii**

FFF. *Color of spines reddish brown to black, usually with purplish joints* .... 19. **phæacantha**
20. **Camanchica**
21. **macrocentra**
22. **nigricans**

EE. *Size of joints small: joints variable in shape: plants mostly low or prostrate. (Some forms of O. humifusa have moderately large joints.)* .... 23. **filipendula**
24. **humifusa**
25. **vulgaris**
26. **Pes-corvi**

DD. *Fr. dry, more or less spiny*.....27. **ursina**
28. **hystricina**
29. **polyacantha**
30. **rutila**
31. **arenaria**
32. **fragilis**
AAA. *Articulations or joints similar, more or less cylindrical.*
B. *Species from S. Amer.*
C. *Joints cylindrical, mostly elongated*.....................33. **cylindrica**
34. **vestita**
35. **clavarioides**
36. **Salmiana**
CC. *Joints globose to broadly obovate*...37. **Darwinii**
38. **diademata**
BB. *Species from N. Amer.*
C. *Spines without sheaths: plants mostly small, with clavate joints*......................39. **pulchella**
40. **clavata**
41. **Grahamii**
42. **Schottii**
43. **Emoryi**
44. **invicta**
CC. *Spines sheathed: joints cylindrical or nearly so, more or less elongated.*
D. *Number of spines variable, always more than one.*
E. *Fr. dry, usually spiny*.....45. **Davisii**
46. **acanthocarpa**
47. **echinocarpa**
48. **Bernardina**
49. **serpentina**
EE. *Fr. fleshy, proliferous*......50. **prolifera**
51. **fulgida**
EEE. *Fr. fleshy, rarely proliferous*.52. **Bigelovii**
53. **imbricata**
54. **arborescens**
55. **spinosior**
56. **Whipplei**
57. **versicolor**
58. **tetracantha**
DD. *Number of spines few, usually one, rarely more or wanting*..59. **arbuscula**
60. **leptocaulis**
61. **ramosissima**

1. **brasiliénsis,** Haw. A large, tree-like plant reaching a height of 15–18 ft., numerously branched, with a thick, roundish crown and an upright trunk, 4–6 in. diam., and bearing numerous spines 1 in. or less in length: joints of two kinds, cylindrical, unarticulate, elongate ones and others which are shorter and much flattened and which arise as offshoots from the former; the latter lf.-like, thin, 2–6 in. long, oblong, rarely oblong-lanceolate or orbicular, dark green, margin angular, sometimes irregular: areoles with short gray wool and numerous brown bristles; spines usually 1, sometimes 1–3 small additional ones, 1–2½ in. long, mostly from the marginal areoles, white, with brownish tips: fls. numerous, citron-yellow, 2 in. wide: fr. globose or ellipsoidal, yellow, about 1½ in. diam. Brazil and southward.—One of the species most frequent in cult.

2. **galapagèia,** Hensl. An upright, tree-like plant 6–13 ft. high, with a circular, spreading crown and a very spiny trunk, 6–8 in. diam., and light-colored bark becoming loosened and hanging in fragments from the older sts.: joints elliptical to oblong, thick, 10–14 in. long: spines at first 3–4, spreading, flexible, increasing in number and size with age, finally covering the joints with long, brush-like bundles: fls. small, less than 1 in. wide, red: fr. subglobose, red. Galapagos Isls.

2598. Fruit of Opuntia Ficus-indica. (×½)

3. **monacántha,** Haw. An upright plant branching from the ground and reaching a height of 6 or more ft.: joints oblong to elliptical, rather thick, terminal ones much thinner, 5–12 in. long, 3–6 in. wide, bright green: areoles with uniformly short wool and yellowish brown bristles; spines 1–2, seldom more, erect, ¼–1½ in. long, yellow to dark reddish brown: fls. yellow, 3 in. wide: fr. ellipsoidal to pyriform, occasionally proliferous, red, somewhat spiny. Argentina.—The horticultural variety, **variegàta,** is in the trade.

4. **aurantìaca,** Lindl. A numerously branched, rather weak, semi-prostrate plant 3–5 ft. high: joints linear-lanceolate to lanceolate, 2–10 in. long, ½–1 in. wide, elliptical in transverse section, dark green, turgid: areoles with a tuft of grayish white wool and bright yellow bristles; spines 4–6, spreading, straight, stiff, brown to yellow, the longest less than 1 in. long: fls. yellow, 1½–2 in. wide: fr. carmine-red, globose, with short spines; seed with woolly hairs. Argentina.

5. **crinífera,** Salm-Dyck (*O. senìlis,* Parm.). A much-branched, wide-spreading plant, about 3 ft. high: joints obovate to elliptical, 6 in. long and 3–4 in. wide, dark green, occasionally glossy: areoles crowded, small, with white wool, numerous golden yellow bristles, and a variable number of long silky hairs; spines 6–8, later more, white, glistening, reaching 1 in. long, the long silky hairs particularly developed on the under side of the young joints: fls. 3½–4 in. wide, golden yellow, often reddish. Brazil(?).

6. **microdàsys,** Lehm. An erect, wide-spreading plant, rarely more than 3 ft. high: joints elliptical to obovate, 3–4 in. long and nearly as wide, thick, bright green, densely pubescent: areoles with short, whitish wool and numerous golden yellow bristles of variable lengths; spines wanting: fls. greenish to lemon-yellow, about 2 in. wide: fr. comparatively small, oval, less than 1 in. diam., armed with numerous yellow bristles; flesh whitish. N. Mex., southward.

Var. **rùfida,** K. Schumann. Of more robust growth: joints rounder and larger, paler green, the bristles inclined to reddish brown. Mex.

7. **basilàris,** Engelm. & Bigel. Fig. 2597 (adapted from Pacific R. R. Report). A low, spreading plant, rarely 1 ft. high: joints thick, variable, usually broadly obovate, with more or less truncate top and branching from the base, 4–7 in. long and 2–4 in. wide, bluish green, and very minutely pubescent: areoles depressed, close together, and with brownish yellow wool and numerous short yellowish brown bristles; spines wanting, rarely present: fls. dark purple, rarely white, 3 in. or more diam.: fr. short, thick green, becoming white and dry at maturity and filled with many large white seeds. S. W. U. S. and N. Mex.

Var. **ramòsa,** Parish. A smaller plant, with joints branching from the upper end, and usually glabrous. S. Calif.

Var. **Trelèasii,** Coult. Differs from the species in having larger orbicular or obovate joints, with terete base, and larger lvs. S. Calif.

8. **pubérula,** Pfeiff. A numerously branched and upright plant, 2–3 ft. high: joints obovate or somewhat rounder, when young covered with very soft pubescence which becomes bright green with age: areoles with short brownish yellow wool and numerous short amber-colored bristles; spines 5–7, 1 in. or more in length, straight, cylindrical, white, with amber-colored base, shining, the lower ones the longer: fls. 1½–2 in. wide, greenish yellow: fr. oval, 1½ in. diam., the many areoles bearing short wool and many bright amber-colored bristles; flesh sweetish; seeds many, correspondingly small. Mex.

9. **leucótricha,** DC. (*O. fulvispìna,* Salm-Dyck). An upright, numerously branched plant, sometimes reaching the height of 10 ft.: joints elliptical or narrower, mostly rounded at the end, 8–10 in. long and half as wide, dark green: areoles small, with white or whitish gray wool and numerous short brown bristles; spines very slender, mostly 4 at first, but later as many as 10–12; some reach the length of 3–4 in., becoming bristle-like and very flexible: fls. 2–3 in. wide, yellow, with reddish center: fr. spherical, 1–1¼ in. diam., pale green to white, thickly beset with velvety wool and brownish yellow bristles; pulp sweet, edible. Mex.

2599. Opuntia Tuna.

10. **triacántha,** Sweet. An upright, tree-like plant, reaching 10–12 ft. in height: joints often very large, occasionally 18 in. long and 10 in. wide, obovate, thick, grayish green: areoles remote, from 1¼–1½ in. apart, with short grayish wool and yellow bristles; spines 3–4, white, with yellow points and bases, 1 in. or less long: fls. 2½–3 in. wide, carmine to orange-yellow: fr. elliptical, 1½–2 in. long; pulp acid. W. Indies.

11. **candelabriformis,** Mart. An upright, sparingly branched plant, 2–4 ft. high: joints elliptical to obovate, thick, dark green, 3–10 in. long and half as wide: areoles with brownish white wool, later becoming gray, and numerous white bristles; spines 4–5, of which 3 are very strong, white, 1¼ in. or less in length: fls. 2½–3 in. wide, carmine-red: fr. spiny. Mex.

12. **crássa,** Haw. (*O. glaùca,* Hort.). A sparingly branched, upright plant, 4–6 ft. high: joints oblong to ovate, 3½–5 in. long and two-thirds as wide, glaucous, greenish blue, thick: areoles with brownish wool, and few bristles of same color; spines usually wanting, sometimes ½in. or less long, straight and needle-like. Mex.

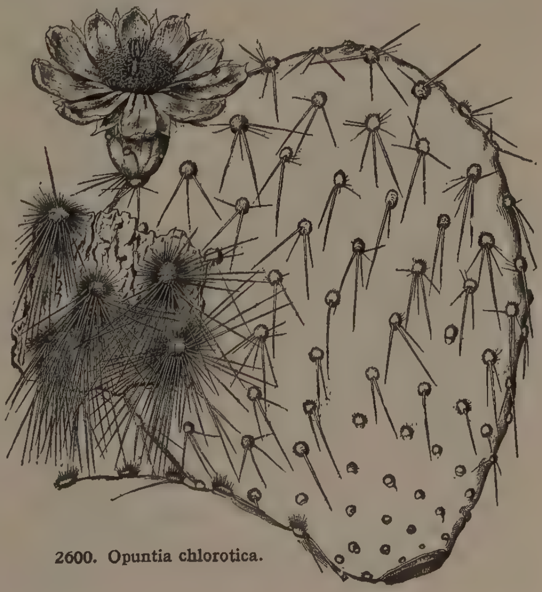
13. **Fìcus-índica,** Mill. (*O. gymnocárpa,* A. Web.). INDIAN FIG. Fig. 2598. An erect, tree-like plant, reaching the height of 10–15 ft., and with a woody cylindrical trunk: joints elliptical or oblong, often with bluish bloom, thick, often 18 in. long and one-third as wide: areoles orbicular and sparingly covered with white wool and yellow bristles; spines usually wanting, occasionally 1–2 small weak ones are present: fls. yellow, expanding to 3–4 in. diam.: fr. yellow, with reddish pulp, bristly, 2 in. diam., edible. Mex. J.H. III. 68:447.—A species widely grown throughout the warm temperate regions of the world. In some regions, escaping from cult., it has become a troublesome weed. Frequently cult. for its fr. under the name of Indian fig.

14. **polyántha,** Haw. A much-branched, spreading plant, 3 ft. or less in height: joints oblong to obovate, dark green, weak-spined, 4–6 in. long and 3–4 in. wide: areoles with white wool and brown bristles; spines 3–8, slender, golden yellow, seldom over ¾in. long: fls. 2½ in. wide: fr. broadly oval, deep red. W. Indies(?). For. var. **albispìna** consult *O. polyacantha,* No. 29, of which it is perhaps a form.

15. **Tùna,** Mill. (*O. hórrida,* Salm-Dyck). Fig. 2599. An erect, wide-spreading, tree-like plant, rapid-growing and frequently 10–12 ft. high: joints deep green, mostly elliptical, 10–14 in. long and 6–10 in. wide: areoles with whitish wool which later becomes dirty gray, and a fascicle of long brownish yellow bristles; spines 4–6, rigid, stout, yellow, frequently subulate, spreading, unequal in length, 1–2 in. long: fls. 3–4 in. wide, yellow, fading to red: fr. pear-shaped or rounder, 1–1½ in. diam., sweet, edible, dark reddish purple. W. Indies and Mex.—Probably the most extensively cult. of all the opuntias. Under the name of "tuna" it has been grown in S. W. U. S., W. Indies and Mex. since the earliest Spanish possession. It is extensively grown both for its fr. and as a hedge plant. It has escaped from cult. and become naturalized in N. and S. Afr., S. Eu., S. W. Asia and Austral., and in some places has become a troublesome weed.

16. **chlorótica,** Engelm. Fig. 2600 (adapted from Pacific R. R. Report). A compact, upright, moderately branched plant, from 3–6 ft. high, the trunk and main sts. becoming woody and terete, and densely covered with long straw-colored bristles and spines: joints orbicular, somewhat glaucous, 6–10 in. diam.: areoles crowded, with fine, gray wool and very numerous golden yellow bristles of unequal length; spines 3–6, rarely none, on old sts. occasionally 40 or more, unequal angular, golden yellow, deflexed, usually 1 in. or less long: fls. yellow, 2–3 in. diam.: fr. deep purple, moderately bristly, edible, 1½ in. diam., broadly obovate to globose; seeds comparatively small, sometimes sterile. S. W. U. S.

17. **pycnántha,** Engelm. An upright, moderately branched plant, 3–5 ft. high: joints oval to orbicular, occasionally somewhat pointed at the ends, 4–8 in. long, sometimes pubescent, armed with a densely interwoven covering of mostly deflexed spines: areoles crowded, approximately ⅓in. apart, with dark brown wool and numerous long, yellow bristles; spines 3–7, on old sts. 20 or more, straw-colored to ashy, mostly less than 1 in. long: fls. greenish yellow, 2–3 in. broad: fr. obovate, 1½ in. diam., and covered with numerous spines and bristles. Low. Calif.



2600. Opuntia chlorotica.

18. **Éngelmannii,** Salm-Dyck. Fig. 2601. An erect to semi-prostrate, profusely branching, coarse plant, 2–5 ft. high, forming large, impenetrable thickets, usually with a short, more or less terete, woody trunk, with grayish bark which becomes unarmed with age: joints broadly obovate to orbicular, pale to bluish green, very variable in size, in large specimens 12–14 in. long and nearly as wide, moderately thick: areoles remote, about 1 in. apart, with gray wool and large, rigid, gray to yellow, unequal bristles: spines mostly 2–4, sometimes 1–3 small additional ones, very variable, horny, variously colored, mostly yellow, or white with reddish base, usually compressed or angular and curved or twisted: fls. yellow, red within, fading to red, 2½–3 in. diam.: fr. broadly pyriform to globose, frequently 2 in. diam., dark purple, with insipid purple flesh. U. S. and Mex.—This species, with its numerous varieties, is the most widely distributed and abundant of the large, flat-stemmed opuntias in the U. S. It varies greatly in different localities, and its many forms have not as yet been adequately defined.

2601. Opuntia Engelmannii. (×⅙)

19. **phæacántha,** Engelm. A diffuse, semi-prostrate plant, 1–2 ft. high, and freely rooting from lower margin of joints: joints broadly obovate, moderately thick, 4–6 in. long: areoles about 1 in. apart, with short wool and reddish or brownish bristles; spines mostly toward margin or on apex of joints, 2–5, straight and stiff, reddish brown to almost black with lighter tips, 1–2½ in. long: fls. 2½ in. broad, yellow: fr. usually long-pyriform, 1 in. or less diam. and twice as long, purple, with greenish acid pulp. S. W. U. S. and Mex. Var. **màjor,** Hort., is a good form.—This species and a number of the following become deep purplish green during autumn and winter. In the spring they lose their purplish color to a large extent and take it on again in the fall. The spines are also much darker in winter than in summer.

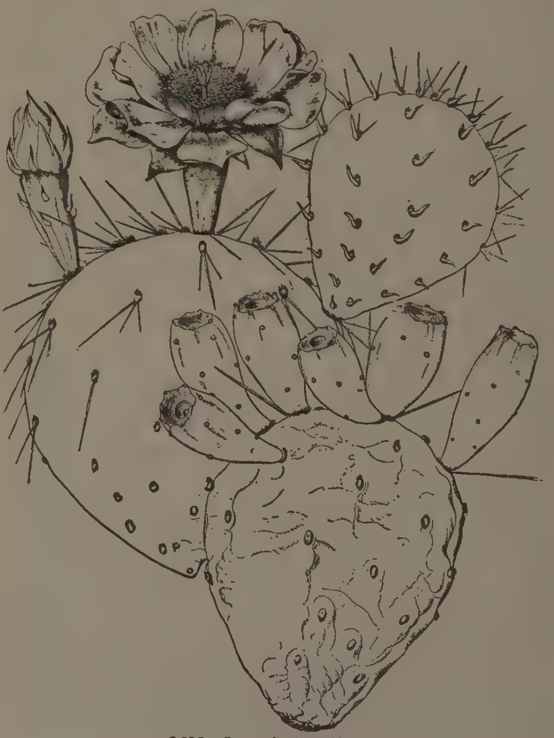
20. **Camánchica,** Engelm. & Bigel. A prostrate, widely spreading plant 1–2½ ft. high, and freely rooting at the lower margin of the joints: joints broadly obovate to orbicular, 4–6 in. long, moderately thick: areoles about 1 in. apart, with light brown short wool and yellowish brown bristles, mostly armed; spines very variable, usually 1–3, sometimes 3–6, on marginal areoles, reddish to blackish brown with lighter tips, variable in length, sometimes 2½ in. long: fls. 2½–3 in. wide, yellow, with reddish center: fr. oval to globose, sometimes pyriform, deep red, sweet, edible, 1–1½ in. diam. S. W. U. S. Var. **gigantèa,** Hort., of the trade proves to be *O. phæacantha.*

21. **macrocéntra,** Engelm. A semi-prostrate, spreading plant, 2–3 ft. high: joints strikingly purple-green, very thin, broadly obovate to nearly orbicular, 5–9 in. diam., with a few remarkably long spines on the marginal areoles: areoles about 1 in. apart, grayish wool and short grayish yellow bristles; spines rarely wanting, usually 1–2, reddish brown to almost black, annulate, 3–5 in. long, slender and straight or variously twisted, sometimes 1–3 much smaller, lighter colored, secondary spines: fls. 3 in. wide, yellow: fr. oval to globose, rarely ovate, 1 in. diam., red; pulp sweet, edible. S. W. U. S., Mex.—This species is remarkable for its exceedingly long, dark spines and purple joints.

22. **nígricans,** Haw. A large, robust, upright plant, 2–5 ft. high: joints usually obovate, dark green, rarely tinged with purple, about 10 in. long and 6 in. wide, moderately thick: areoles with short, grayish wool and yellowish brown bristles; spines 1–2, awl-shaped, 1–2 in. long, strong, dark brown, at first yellowish: fls. 1½–2 in. wide, yellow with red center. Mex.—Frequent in cult.

23. **filipéndula,** Engelm. A small, semi-prostrate plant, freely branching from the base of the joints, rarely 10 in. high and with thick, tuberous, moniliform roots: joints small and thin, bluish, glaucous, rarely 3 in. greatest diam., orbicular to broadly obovate, sometimes diamond-shaped, frequently flattened at the top and broader than long: areoles orbicular and with an abundance of whitish wool and many long, slender, yellowish green bristles, which are very conspicuous, particularly on the older joints; spines sometimes wanting, when present usually 1–3, rarely more, white, very slender and flexible, 1–2 in. long, mostly marginal: fls. yellow, 1½–2 in. diam.: fr. clavate to narrowly obovate, 1½ in. long and half as wide, greenish yellow, with few seeds. Texas to Ariz., extending into Mex.

24. **humifùsa,** Raf. (*O. Rafinésquii,* Engelm. *O. mesacántha,* Raf.). Fig. 2602 (adapted from Pacific R. R. Report). A wide-spreading, prostrate plant, freely rooting from the lower margin of the joints, roots sometimes tuberous: joints obovate to orbicular, usually 2–5 in. long and 2–4 in. wide, sometimes twice as large, dark to light green: areoles with gray wool and bright reddish brown bristles; spines sometimes wanting, when present 1–3 and mostly marginal, stout, 1 in. long, white with darker tips and bases, frequently 1–3 small secondary spines also present: fls. 3 in. or less diam., golden yellow, frequently with reddish center: fr. slender-clavate or broader, 1½–2 in. long, yellowish red



2602. Opuntia humifusa.

to purple, with insipid purplish pulp; seeds comparatively large. W. Cent. U. S.—An exceedingly variable species of wide distribution and imperfectly known. Many varieties have been described, some of which are in the trade. The extreme forms vary greatly from the type. Of these forms vars. **Greènii, oplocárpa, cymochìla, stenochìla** and **macrorhìza,** Hort., have appeared in the trade.

2603. Opuntia ursina.

25. **vulgàris,** Mill. Barberry Fig. A diffuse, prostrate plant a foot or less high: joints usually resting on the ground and rooting from the lower margin, obovate to suborbicular, thick, 2–4 in. greatest diam., pale green: areoles with grayish wool and a few short, greenish yellow bristles; spines rarely present, when present usually 1, stout, erect, less than 1 in. long, yellow, often variegated: fls. 2 in. wide, pale or chrome-yellow: fr. obovate to spherical, 1 in. diam., red, flesh insipid. E. U. S. Hardy in Mass.

26. **Pes-córvi,** LeConte. A small, diffuse, prostrate plant, rarely 1 ft. high: joints fragile, somewhat tumid, narrowly ovate to obovate or oblong, 2–4 in. long and less than half as wide, frequently much smaller, very thick, broadly oval in transverse section, bright green with a bluish tinge: areoles circular, with short, whitish wool and a few short, slender, pale bristles; spines rarely exceeding 2, frequently none, slender, white, often brownish, less than 1 in. long: fls. yellow, 1½ in. wide: fr. obovate, bristly, purplish, 1 in. or less diam.; seeds comparatively large, very few. Fla.

27. **ursìna,** Web. Grizzly-Bear Opuntia. Fig. 2603. An upright, diffuse plant, 1–2 ft. high: joints oblong to obovate, grayish green, thick, 3–6 in. long and 2–4 in. wide: areoles with white wool and numerous yellow bristles; spines 12–20, reddish white, very slender and bristle-like, sometimes 4 in. long, frequently almost completely hiding the epidermis of the plant: fls. 2½–3 in. wide, reddish yellow. Calif.

28. **hystricìna,** Engelm & Bigel. A semi-prostrate, spreading plant, ½–1½ ft. high: joints obovate to orbicular, 3–5 in. long, moderately thick and very spiny: areoles with grayish wool and yellowish red bristles; spines 10–15, 2 in. long or shorter, white or dusky, slender, flexile, angular and twisted: fls. light purple, 2–3 in. wide: fr. broadly obovate, 1 in. diam., armed with many long spines. S. W. U. S.

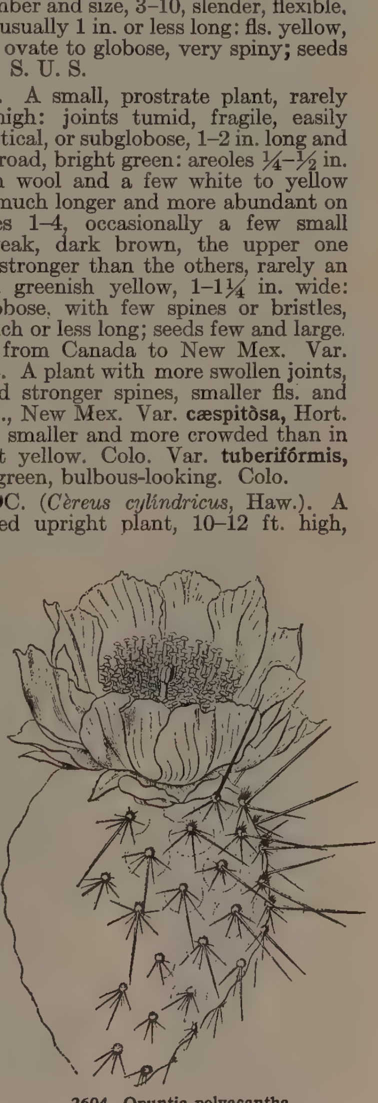
29. **polyacántha,** Haw. (*O. missouriénsis,* DC. *O. fèrox,* Haw. *O. spléndens,* Hort.). Fig. 2604 (adapted from Pacific R. R. Report). A prostrate, wide-spreading plant, rarely rising 1 ft. above the ground: joints variable, from elongate-obovate to orbicular, usually bright green, frequently wrinkled and tuberculate, 2–6 in. long: areoles about ½in. apart, with short, grayish wool and long, reddish brown bristles; spines 0–12, very variable in length, number and color on different forms and plants from different localities, mostly marginal, white or variously tinged with red or brown, slender, twisted and flattened, some reaching a length of 3 in.: fls. yellow, darker within, 2–2½ in. wide: fr. broadly ovate or subglobose, ¾–1 in. diam., armed with numerous rather short spines; seeds comparatively large. W. Cent. U. S.—A species of wide distribution and very variable, some high mountain forms entirely without spines, while other forms are armed with a close network of closely interwoven ones. A number of the forms have been segregated as varieties, of which the best known are **rufispìna, platycárpa, microspérma, albispìna** and **trichóphora,** Hort. All the forms appear to run together and the varietal distinctions are of doubtful value. Hardy in Mass.

30. **rùtila,** Nutt. A low, diffuse plant, ½–1 ft. high: joints tumid, readily becoming detached, and covered with a close network of slender, interwoven, light gray spines, thick, elongate-ovate, 2–4 in. long: areoles crowded, less than ½in. apart, with short, white wool and yellow bristles; spines 3–5, sometimes a few short accessory ones, slender, reddish gray to white, with darker tips, 1¾ in. or less in length, larger ones often flattened and twisted: fls. red, 1½–2 in. wide: fr. broadly ovate to subglobose, usually armed with very long, interwoven spines; seeds comparatively large. S. W. U. S.

31. **arenària,** Engelm. A diffuse plant with upright terminal joints, rarely 1 ft. high: joints thick, obovate, 2–5 in. long and half as wide, tumid, strongly tuberculate: areoles crowded, ¼–½in. apart, with sparse white wool and numerous yellowish brown bristles; spines very variable in number and size, 3–10, slender, flexible, white to ashy gray, usually 1 in. or less long: fls. yellow, 2–2½ in. broad: fr. ovate to globose, very spiny; seeds large and irregular. S. U. S.

32. **frágilis,** Haw. A small, prostrate plant, rarely more than 4 in. high: joints tumid, fragile, easily detached, oval, elliptical, or subglobose, 1–2 in. long and nearly as thick as broad, bright green: areoles ¼–½ in. apart, with whitish wool and a few white to yellow bristles, which are much longer and more abundant on older joints; spines 1–4, occasionally a few small additional ones, weak, dark brown, the upper one usually longer and stronger than the others, rarely an inch in length: fls. greenish yellow, 1–1¼ in. wide: fr. ovate to subglobose, with few spines or bristles, mostly sterile, an inch or less long; seeds few and large. Rocky Mt. region from Canada to New Mex. Var. **brachyárthra,** Coult. A plant with more swollen joints, more numerous and stronger spines, smaller fls. and more spiny fr. Colo., New Mex. Var. **cæspitòsa,** Hort. Joints bright green, smaller and more crowded than in the type: fls. bright yellow. Colo. Var. **tuberifórmis,** Hort. Joints olive-green, bulbous-looking. Colo.

33. **cylíndrica,** DC. (*Cèreus cylíndricus,* Haw.). A moderately branched upright plant, 10–12 ft. high, with main sts. 2–2½ in. diam., new growth dark green, the comparatively long (½in.) lvs. persisting for some time: areoles depressed, with a little white wool, a few white bristles and some long white hairs; spines at first 2–3, erect, rather stiff, ½in. or less long, at first whitish yellow, later grayish: fls. rose-red, 2–2½ in. wide from end of joints: fr. pyriform, 2–2½ in. long, yellowish green, somewhat spiny. Chile. Var. **cristàta** is offered in cult.



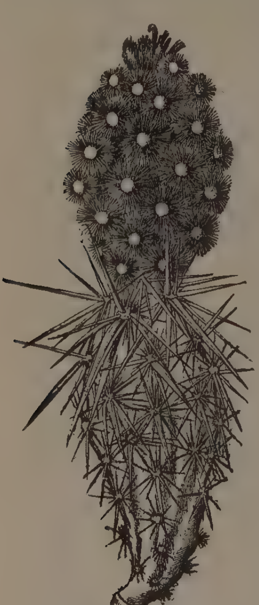
2604. Opuntia polyacantha.

34. **vestìta,** Salm-Dyck. A small, upright, numerously branched, ramifying plant a foot or more in height: joints rather short, 1–2 in. long and half as thick, usually dark green: areoles with white to grayish wool and a number of long, rather soft, grayish white hairs; spines 4–8, either short, flexible and grayish yellow or four times as long (½–¾in.), stiff and red: fls. 1–1½ in. wide, mostly lateral, dark red: fr. ellipsoidal, ¼–¾in. long, bright red and covered with grayish wool. Bolivia.

35. **clavarioìdes,** Link. & Otto. A low, numerously branched, spreading plant, 1–1½ ft. high: joints rather fragile and slender, ½in. thick, cylindrical or somewhat clavate, frequently cristate, with numerous terminal, slender branches: lvs. extremely small: areoles close together, small, with white wool: spines 4–10, sometimes fewer, very small and appressed, white,: fls. 1–1½ in. wide and twice as long, greenish red: fr. elliptical, ½–¾in. long; seeds with woolly hairs. Chile. Var. **cristàta** is offered.

36. **Salmiàna,** Parm. A numerously branched, upright plant, about 3 ft. high, with very long, proportionately slender branches: sts. about ⅗in. diam., with rough, fissured or cracked, grayish brown or lead-colored bark, the terminal joints pencil-like, 3–10 in. long and ⅓–½in. wide: areoles on young growth with sparse white wool and few bristles, on older growth the bristles are very numerous and somewhat spine-like; spines 3–5, spreading, about ⅓in. long, grayish: fls. 1 in. wide, red: fr. pyriform, 1–1¼ in. long, scarlet-proliferous, rarely fertile. Brazil.

37. **Dárwinii,** Hensl. A small, numerously jointed, prostrate, ramifying plant a few inches high: joints globose to broadly obovate, 1½ in. greatest diam., olive-green: areoles with yellowish wool and few bristles; spines rigid, 1½–2 in. long, the lower ones shorter and darker: fls. only on top of terminal joints, 1–1½ in. wide, yellow; ovaries as large as the joints. S. S. Amer.



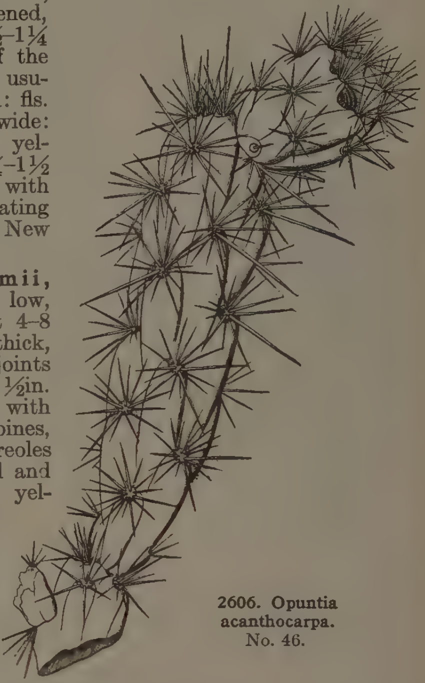
2605. Opuntia clavata.

38. **diademàta,** Lem. (*O. papyracántha,* Phil.). A low, moderately branched, spreading plant, rarely more than 4 in. high and forming dense patches several feet diam.: joints 1–1½ in. long and nearly as thick, globose to broadly clavate, usually growing several in succession, one above the other, young growth bright green, soon becoming grayish: areoles with abundant white wool and brownish black bristles; spines 1–2, papery, flexible, white or brownish with darker tips, ⅕ (?) in. long, and half as wide: fls. rather small, pale yellow. Argentina. R.B. 40, p. 186.

39. **pulchélla,** Engelm. A small, spreading, numerously branched plant, seldom more than 6 in. high: joints ascending, 2½ in. long and ½in. thick, obovate to clavate: areoles crowded, with white wool, and yellowish bristles which become more numerous and larger with age; spines 10–15, of variable length, the central one flattened, flexible, somewhat papery, 1 in. long: fls. from the top of the joints, purplish to rose-red, 1–1½ in. wide: fr. broadly clavate, 1 in. long, with long, hair-like, flexible white spines, dry. Nev., Ariz.

40. **clavàta,** Engelm. Fig. 2605 (adapted from Pacific R. R. Report). A low, spreading plant, 4–6 in. high, forming dense mats of ascending joints 4–5 ft. diam.: joints 1–3 in. long and 1 in. thick, armed with numerous short, flat spines: areoles with white wool and rigid, white bristles; exterior spines 6–14, white, ⅙–¾ in. long, interior 4–7, larger, flattened, scabrous and ½–1¼ in. long, one of the central spines usually very broad: fls. yellow, 1½ in. wide: fr. long-clavate, yellowish, dry, 1¼–1½ in. long, armed with many white radiating bristles. Nev., New Mex.

41. **Gràhamii,** Engelm. A low, spreading plant 4–8 in. high, with thick, fusiform roots: joints 2–3 in. long and ½in. thick, armed with long, dark spines, bright green: areoles with white wool and numerous long, yellowish brown, rigid bristles which become very conspicuous on old joints; exterior spines 4–8, ⅓in. long, interior 4–7, more rigid and longer (1½–2 in.), reddish to ashy brown: fls. yellow, 1½–2 in. wide: fr. ellipsoidal, 1½–1¾ in. long and half as wide, armed with many large, radiating spine-like bristles. New Mex., Texas.



2606. Opuntia acanthocarpa. No. 46.

42. **Schóttii,** Engelm. A wide-spreading, prostrate plant, 4–6 in. high, with numerous short, curved branches: joints short-calvate, rarely more than 2 in. long and armed with numerous dark-colored spines: areoles with white wool and very few bristles; exterior spines 6–10, very variable, ½in. long; interior usually 4, flattened or irregular, 1½–2 in. long, brownish red: fls. greenish yellow to reddish, 1½ in. wide: fr. short-clavate, the numerous areoles covered with white wool and many short bristles. Texas, Mex.

43. **Émoryi,** Engelm. A prostrate and spreading plant with comparatively large, long-clavate, curved joints and reaching a height of 8–12 in.: joints 4–7 in. long and 1–1½ in. thick, with large, elongated tubercles: areoles remote, with white wool and a few long (½in.) yellow bristles; spines numerous, exterior 10–20, ½in. or less long, very bulbous at base; interior 5–10, brownish to reddish black, more or less flattened and sometimes 3 in. long: fls. yellow, reddish within, 1½–2 in. wide: fr. ellipsoidal, yellow, 2–2½ in. long and 1 in. wide, armed with numerous bristles and spines. S. W. U. S., N. Mex.

44. **invícta,** Brandegee. A numerously branched, spreading plant, 10–14 in. high, bluish green and armed with many rigid, erect spines: joints 4–6 in. long and 2–2½ in. thick, nearly cylindrical: areoles with whitish wool and yellowish red bristles; spines 15–25, exterior 6–12, ½in. or less long; interior 10–15, very strong and rigid, 1–2 in. long, more or less flattened: fls. yellow, 1½–2 in. wide: fr. broadly obovate, dry, armed with numerous reddish spines and bristles. Low. Calif.

45. **Dàvisii,** Engelm. & Bigel. A procumbent, spreading shrub, with firm, woody skeleton, 1–2 ft. high:

joints 4–7 in. long and ⅓–½in. thick: areoles with short, white wool and numerous straw-colored bristles; spines usually 8–13, exterior ½in. or less long; interior 4–7, triangular, brownish, with lighter tips, ¾–1¼ in. long, very loose-sheathed: fls. greenish yellow, 2–2¼ in. wide: fr. clavate, 1 in. or more long, often sterile, spiny. Texas to Calif.

46. **acanthocárpa,** Engelm. & Bigel. Fig. 2606 (adapted from Pacific R. R. Report). An arborescent, erect plant, 4–8 ft. high, with dense reticulate-tubular skeleton and ascending, spreading branches: joints usually 4–10 in. long, sometimes 20, and ¾–1 in. diam.: areoles with short, white wool and scanty bright yellow bristles; spines very variable in length and numbers on different plants, usually 8–25, 1½ in. or less long, with loose straw-colored or brownish sheaths: fls. greenish yellow, with reddish centers, conspicuous for stamens with stout red filaments, 1¼–1½ in. wide: fr. subglobose to pyriform, 1 in. diam. and usually armed with many long, stiff spines. Ariz. and Calif.—A factory has been established at Tempe, Ariz., where the wood of this species is made into light furniture, picture-frames, and the like.

2607. Opuntia Bigelovii.

47. **echinocárpa,** Engelm. & Bigel. A low, spreading shrub, with reticulate woody skeleton, rarely more than 1¼ ft. high: joints 1½–3 in. long, rarely 4–6 in., ¾in. thick, somewhat clavate: areoles with short white wool and a few coarse, straw-colored bristles, spines very variable in length and number, exterior 8–16, 1¼ in. or less long; interior usually 4, forming a cross, 1–1½ in. long, with loose white or straw-colored sheaths: fls. greenish yellow, 1¼–1¾ in. wide: fr. depressed-globose or hemispherical and armed with many long (1–1½ in.) spines on the upper areoles. Utah, Ariz., and Calif.—The fr. of this species, like most others with dry fr., ripens in the early summer, while most species with fleshy fr. do not mature them until fall or the following spring.

48. **Bernardìna,** Engelm. A slender, branched, upright shrub, 3–5 ft. high, usually with several long, straight sts. arising from the base: joints 4–24 in. long and ¾in. thick, armed with numerous short spines: areoles with grayish white wool and numerous yellow bristles; spines yellow or brownish, 8–14, usually with inconspicuous sheaths, ¾in. or less long: fls. greenish yellow, 1–1½ in. wide: fr. obovate, 1 in. long, armed with numerous rather short spines. S. Calif.

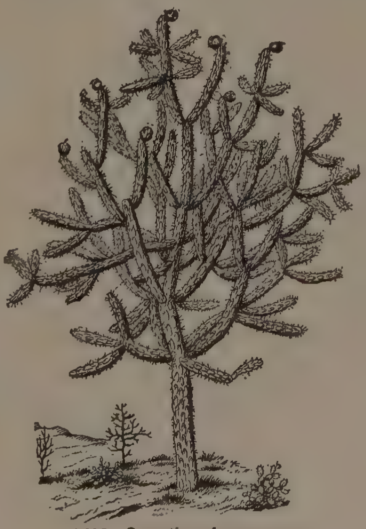
49. **serpentìna,** Engelm. A prostrate, rarely ascending, sparingly branched shrub, a few inches to 2 ft. high: joints much elongated, 6–20 in. long and ½–1 in. thick: areoles with short white wool and whitish bristles; spines comparatively short, usually 7–9, sometimes 15 or more, yellowish or rusty, ½in. or less long: fls. greenish yellow, 1–1½ in. wide: fr. hemispherical, ½–¾ in. diam., armed with numerous short spines and long woolly hairs. S. Calif., Low. Calif.

50. **prolífera,** Engelm. An arborescent, thick-stemmed plant, 3–8 ft. high, with numerous horizontal, spreading branches, the erect trunk sometimes 8 in. diam : joints short-cylindrical, rounded at the ends, very succulent, tumid and readily detached, bright green, 2–6 in. long and 1¼–2 in. thick: areoles with white wool and on older joints with numerous straw-colored bristles; spines variable, usually 6–10, with conspicuous, loose, yellowish or rusty sheaths and much-barbed, usually about 1 in. long: fls. 1¼–1½ in. wide, greenish red: fr. subglobose, ¾–1¼ in. diam., light green, with few small spines and bristles, pendulous in clusters, frequently sterile. Calif., Low. Calif.

51. **fúlgida,** Engelm. A numerously branched arborescent plant, often 10–12 ft. high, with erect trunk 8–14 in. diam., having a thick, grayish, scaly, unarmed bark: joints congested toward the ends of the larger branches, ovate to ovate-cylindrical, 2–8 in. long and often 2 in. thick, very fragile and tumid, easily becoming detached and taking root, bluish green, somewhat glaucous: areoles with white wool and bright straw-colored bristles; spines on young growth 5–8, increasing yearly until ultimately 30–50, finally deciduous, with loose, glistening, white or straw-colored sheaths 1½ in. or less long: fls. ¾–1 in. wide, pink: fr. obovate to globose, light green, pendulous, in large, proliferous clusters, sometimes 50 in a single cluster. S. W. U. S. and N. Mex.—The common "cholla" of the Ariz. plains, where it often becomes a fair-sized tree and notable for its formidable armor of barbed spines completely hiding the surface of the plant. Var. **mamillàta,** Coult. Differs in having fewer, shorter spines.

52. **Bigelòvii,** Engelm. Fig. 2607 (adapted from Pacific R. R. Report). An erect, compact plant, 4–6 ft. high, rarely higher, with fragile woody skeleton which does not appear in joints of the first year's growth, the most densely spine-covered and difficult to handle of the cylindrical opuntias: joints readily detached and forming formidable burs, ovate, short-elliptical to long and cylindrical, with rounded ends, readily breaking from the plant and taking root, pale green, fragile, tumid, terminal ones frequently 3–5 in. long and half as thick: areoles close together, with white wool and pale yellow bristles; spines 10–20, some very small, increasing in number as sts. become older, straw-colored, loose-sheathed, 1 in. or less long, completely hiding the surface of the plant: fls. greenish red, 1 in. broad: fr. very spiny, ovate, 1¼–2 in. long and one-third as wide, few-seeded, mostly sterile. Ariz., Calif.

53. **imbricàta,** DC. A wide-spreading, irregularly branching shrub, rarely more than 5 ft. high, the trunk and larger branches with dark, rough, unarmed bark: joints frequently 12–14 in. long and 1–1¼ in. thick, with very prominent long, cristate tubercles: areoles with yellowish wool and straw-colored bristles; spines 2–5, of variable length, 1 in. or less long, loosely sheathed, white to straw-colored: fls. 2–2½ in. wide, light purple: fr. unarmed, depressed-globose, with large tubercles, yellow, 1–1½ in. diam., adhering to the plant and drying on the sts. during the winter. Texas and N. Mex.—Usually confused with *O. arborescens,* from which it differs in its smaller growth, different habit, much longer joints, larger, more prominent tuber-



2608. Opuntia arborescens.

cles, and fewer spines. The fr. and fl. also show marked differences.

54. **arboréscens,** Engelm. (*O. stellàta*, Salm-Dyck). Fig. 2608 (adapted from Pacific R. R. Report). An arborescent, numerously branched plant, 4–8 ft. high, with trunk of larger plants having very rough, dark, unarmed bark: joints with moderately prominent, narrow, cristate tubercles, verticillate, horizontally spreading on mostly pendulous, moderately spiny branches, mostly 3–6 in. long and 1 in. or less thick: areoles with dirty-white wool and small yellow to light brown bristles; spines 6–20, variable in length, 1 in. or less, central ones more loosely sheathed, horny or reddish brown, white to straw-colored sheaths: fls. purple, 2–3 in. wide: fr. unarmed or with few spines, conspicuously tuberculate, subglobose, 1 in. diam., yellow to yellowish red. S. W. U. S.—Frequently confused with *O. imbricata* and *O. spinosior*, and intermediate between the two. Differs from the latter in having much larger, more cristate tubercles, fewer spines and different fr.

55. **spinòsior,** Toumey. A small tree, 6–12 ft. high, with numerous verticillate branches, forming a rounded head, the cylindrical trunk usually branching a few feet above the ground, and with rough, dark brown or grayish unarmed bark: joints verticillate and pendulous, ultimate ones usually 4–8 in. long and about 1 in. thick, dark green, frequently more or less purplish, with short, crowded rhombic tubercles: areoles with white to reddish brown wool and usually few, small, variously colored bristles; spines 10–30, increasing in number yearly as the joints become older until finally deciduous, short, and rarely conspicuously sheathed, usually ½–¾ in. long: fls. showy, bright to dark purple, 2–2½ in. wide, in whorls at the ends of the joints: fr. elliptical to oblong, rarely obovate to globose, 1½–2½ in. long, yellow, frequently remaining on the stems during the second year. Ariz., N. Mex.

56. **Whípplei,** Engelm. & Bigel. Fig. 2609 (adapted from Pacific R. R. Report). A spreading, sub-prostrate shrub, rarely more than 2 ft. high, with numerous ascending secondary branches, having short, crowded, prominent tubercles: joints variable, terminal ones clavate, 2–5 in. long and ⅔–¾in. thick, mostly armed on upper half: areoles with short white wool and a few short, light-colored bristles; spines white, very variable, on terminal joints, usually from 1–3 conspicuous loose-sheathed interior ones and several small, deflexed or radiating ones: fls. greenish yellow, crowded at the ends of the joints, 1–1¼ in. wide: fr. unarmed or with few spines, pyriform to subglobose, densely tuberculate, yellow or tinted with scarlet, ½–1 in. diam., drying and remaining attached to the plant during the winter. S. W. U. S. and N. W. Mex.—This plant is frequently confused with *O. spinosior*, probably from confusion in the original description.

2609. Opuntia Whipplei.

57. **versícolor,** Engelm. A small, numerously branched tree, 6–10 ft. high, with rounded head and a short trunk, having smooth, light brown or reddish brown, unarmed bark: joints much elongated, usually 6–12 in. long, sometimes 20, ⅔–¾in. thick, deep green, more or less colored with red and purple: areoles with short gray wool and lighter colored bristles; spines variable, on terminal joints, usually from 5–13, older joints with 10–20, rarely, however, increasing in numbers after the second year, reddish brown, with inconspicuous, close-fitting sheaths, ¾in. or less long: fls. bronze-colored, 1–1½ in. wide: fr. pyriform to clavate, of same color as joints, never yellow, sometimes tinged with red or purple, unarmed or with a few persistent short spines, 1–2 in. long. Ariz., N. Mex.

2610. Opuntia ramosissima.

58. **tetracántha,** Toumey. An irregularly branching shrub, 2–5 ft. high, primary branches from a stout, upright trunk 2–4 in. diam., and bearing numerous short lateral ones at irregular intervals: joints very variable in length, usually 4–10 in. long and ½in. thick: areoles with whitish wool and a crescent-shaped tuft of light brown bristles; spines 4, rarely more or less, ¾–1½ in. long, stout, loosely sheathed, straw-colored, flattened, strongly deflexed, not increasing in numbers on older joints: fls. greenish purple, ½–1 in. broad: fr. obovate to subglobose, ½–1 in. long, juicy, scarlet, unarmed, or with a few stiff deflexed spines. Ariz.—One of the most attractive of the cylindrical opuntias on account of its numerous bright scarlet frs.

59. **arbúscula,** Engelm. A short, numerously branched, round-headed, arborescent plant, rarely reaching the height of 5 ft., but always with an upright, well-defined trunk, having rough, brown, unarmed bark: joints usually 2–4 in. long and ⅓in. wide, easily broken from the plant: areoles comparatively large, with white wool and brush-like tufts of long, slender, yellow bristles; spines yellow, usually 1, frequently a small, slender, additional one at either side, ¾–1½ in. long, loosely sheathed. fls. bronze-colored, ¾–1 in. wide: fr. unarmed, of same color as joints, long, clavate, 1–2 in. long and one-third as wide, mostly sterile, fertile ones with a few remarkably large, irregular-spheroidal seeds. Ariz., Sonora.

60. **leptocaùlis,** DC. (*O. frutéscens*, Engelm.). An erect shrub, 2–4 ft. high, with long, slender, flexible sts. branching from near the ground, and numerous lateral secondary ones, very short, usually unarmed and easily detached: joints about ⅕–¼in. thick: areoles with short white wool and numerous reddish brown conspicuous bristles; spines usually 1, sometimes wanting, erect, stout, frequently 2 in. long, brownish or horny, with a loose yellow sheath: fls greenish yellow, ⅓–½in.

wide, with deflexed perianth: fr. scarlet, succulent, obovate to oblong, rarely globose, ⅓–⅔in. long, frequently proliferous, armed with tufts of long, reddish brown bristles. S. W. U. S. and Sonora. Var. **màjor,** Hort., is advertised.—One of the slenderest of the opuntias. It differs from other species in that the fls. do not open until late in the afternoon. Several forms of this plant occur throughout its range, some of which have been separated as varieties. One of the most frequent of the cylindrical opuntias in cult.

61. **ramosíssima,** Engelm. (*O. tessellàta,* Engelm.). Fig. 2610. A spreading bush, 2–5 ft. high, with numerous slender branches arising from a short trunk, 1–3 in. thick, and having dark, scaly bark: joints ashy to bluish gray, variable in length, ultimate ones 2–6 in., ¼–⅓in. thick: areoles with sparse white wool and a few small yellow bristles; spines sometimes wanting, usually 1, stiff, erect, 1½–2 in. long, loosely sheathed: fls. reddish purple, ½–⅔in. wide, dry, narrowly, obovate, 1 in. long, ⅓in. wide, with 1 or 2 seeds, frequently sterile, armed with numerous long, grayish bristles. Ariz., Calif., Sonora.

O. Bergeriàna, A. Web. Allied to O. nigricans. Forming a shrub 5–10 ft. high: joints obovate or oblong-ovate, 9 in. long, 4½ in. wide: spines varying in number and size, spreading: fls. red, over 1 in. long. G.C. III. 35:34.—*O. cantabrigiénsis,* Lynch. Similar to O. Engelmannii, but differs in the whitish spines and broadly obconical ovary. G.C. III. 33:98.—*O. cervicórnis.* Probably a hybrid. Joints cylindric, strongly tubercled, decumbent, about 5 in. long: spines golden brown: fls. yellow, 2½ in. wide. Colo.—*O. coccinellífera,* Mill.=Nopalea.—*O. cornigàta,* Salm-Dyck, was once advertised, but is little known.—*O. Dèamii,* Rose. ORACH, or French spinach, is a pot-herb cultivated and used much like spinach. It is an annual, grows 5 to 6 feet high, has furrowed stems and arrow-shaped slightly crimped leaves of soft texture. The inflorescence suggests that of amarantus-like plants. The individual flowers are very small, devoid of petals, and greenish or reddish according to variety. For a technical description, see *Atriplex hortensis,* page 427.

There are three main types of orach, based on the color of the leaves. The white variety is most commonly grown; the leaves are pale green, almost yellow. The red or dark red variety has stems and foliage of dark red color, which disappears in cooking; it is occasionally cultivated as an ornamental foliage plant under the name var. *atrosanguinea.* The green variety is perhaps the most vigorous type; the leaves are rounder than those of the white variety and less toothed.

The seed is usually drilled into the open ground in early spring, and usually seedlings are not transplanted but thinned and allowed to stand in the row. The plants are used in their young state, being cooked after the manner of spinach or other "greens." They bear hot weather fairly well, but soon run to seed. Monthly successional sowings are therefore desirable. Orach is little grown in America.

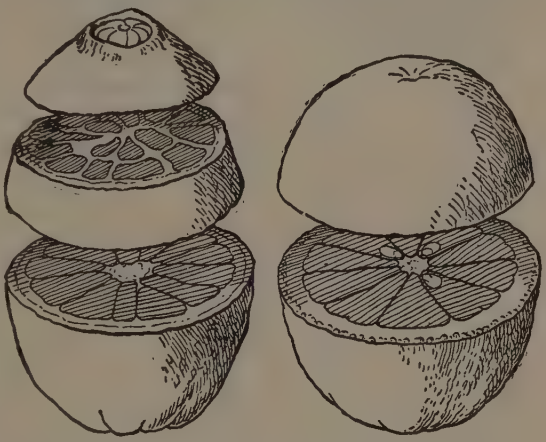
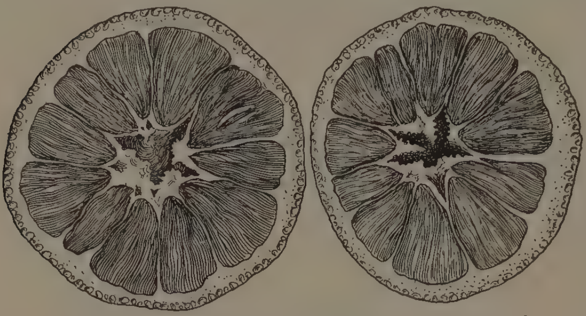
ORANGE. Plate LXXVIII. The orange is one of the oldest of cultivated fruits. Its nativity is still in doubt, but it is probable that it is indigenous to the Indo-Chinese region. It is now widely distributed in all warm-temperate and tropical countries, in many of which it has run wild and behaves like a native plant. In parts of Florida the orange was found wild when permanent settlements were made, but it had probably spread from stock that was introduced by the early Spaniards.



2611. The "navel" structure.—Normal orange on the right; abnormal or navel orange on the left, showing the adventitous cells in the center.

In stature of tree and character of fruit, the orange has varied immensely. Normally, the fruit contains ten compartments or locules; but under the influence of domestication these compartments have been increased, and in some cases a secondary axis, with its accompanying locules, has been thrust into the center of the fruit, causing the "navel" appearance of some varieties (Figs. 2611, 2612). These navel oranges, of which the Washington Navel, or Bahia, is the best known, are chance kinds or varieties, as other varieties are. The immediate cause of this particular kind of variation, as of other variations, is unknown. The Washington Navel was introduced from Brazil in 1870 by the late Wm. Saunders, and by him distributed as the Bahia (see Van Deman, Report of the Department of Agriculture, 1886, page 267). The two "original" trees in California are still standing at Riverside, carefully protected (Fig. 2613). In recent years, some of the odd and grotesque types of Japanese oranges have been introduced into this country, but they will probably always be curiosities rather than commercial pomological products. See A.G. 1890, 333–336. The sweet and sour oranges are considered to be two species (pages 782–784, Volume II), *Citrus sinensis* and *C. Aurantium* respectively. To the former belong nearly all the usual commercial oranges, although the King orange is *C. nobilis,* of which the tangerines, mandarins and satsumas are varieties (Figs. 2614, 2615). The orange belongs to a tribe of three-foliolate plants, and although its leaves appear to be simple, they are really compound. Fig. 2616 shows the articulation above *a*, at which point the blade is jointed to the rachis; this blade is a leaflet, and the side leaflets have not developed, as they do in the trifoliolate orange (*Citrus*, or *Poncirus, trifoliata*).

There are three well-developed orange regions within the confines of the United States: central and southern Florida; the delta region of the Mississippi; California. Parts of Texas and the Mexico-Arizona region will no doubt develop into commercial orange sections in the near future. Until within recent years a large part of the oranges consumed in this country had come from Mediterranean regions, but the Florida and California oranges have taken the place of the imported fruit.



2612. Orange (Satsuma). Showing the multiplication of locules or compartments.

Oranges under glass.

Years ago, oranges were commonly grown under glass in England and parts of the continent. At that time there was no rapid transportation between the orange-growing regions and northern countries, and the orange fruit was a luxury. Special houses, known as "orangeries," were devoted to the culture of the fruit. The trees were ordinarily grown in large tubs or boxes, and were kept in the open in summer and were placed in the orangery in winter. These orangeries were scarcely greenhouses in the modern understanding of the term. In many cases they had slate or shingle roofs, the sides only being provided with an extra extent of glass in the shape of windows. Some of them, however, were houses with glass roofs. As imported oranges came to be more common, these orange-houses gradually fell into disuse. It is doubtful whether there are any of these establishments now standing in this country; but one sees them sometimes in Europe. As the orange trees disappeared, other plants were grown in the house, so that an orangery came to mean a particular kind of house in which plants are grown that will thrive in conditions suited to the orange. It came to be no uncommon thing to see orangeries in which there were no oranges.

The orange tree is still a popular subject in conservatories, however, and in window-gardens. In the latter conditions it rarely produces fruit of any consequence, but the shining evergreen foliage and the very fragrant flowers make the plant interesting and desirable. The plant is subject to scale and mealy-bug, and constant attention must be given to syringing and sponging the foliage. The leading difficulty in the rearing of an orange tree in the dwelling-house is a tendency to have it growing the entire year and to keep it too wet at the roots. After the fruiting season, in late autumn or early winter, the plant should be allowed to rest for a time in order to harden its wood for the next year's bloom. It may then be kept at a temperature of 40° to 50° and fairly dry at the roots. Water should not be withheld entirely, however, because the plant should be kept in such condition that the foliage will not drop. After a period of relative inactivity of one or two months, the plant may be set in a sunny place and given a somewhat higher temperature, and water and liquid manure may be applied at the roots. It should be in bloom in the summer and early autumn. Best results are secured if the roots are somewhat confined. When the plant is small, it may be potted on from time to time; but after it has attained the height of 5 or 6 feet, it should not be given more root-room than a small tub or a half-barrel. Ordinarily, it will not need repotting for several years at a time after it has attained this size. Some of the surface soil may be removed from time to time and fresh soil added and liquid manure applied. Usually the plants are grown from seeds, and they vary as peaches or apples do. Some of the plants may give desirable fruit, but the larger part of them will give fruit of indifferent or even inferior quality. If the best kind of fruit is wanted, the young plants should be budded after they are well established in the pots. Buds may be secured from any tree that bears a desirable fruit, or they may be brought from the South.

In recent years the Otaheite orange (described in Volume II, page 785) has come into prominence as a pot-plant. It is known botanically as *Citrus taitensis* (Fig. 2617). It is undoubtedly the best form of orange for growing in the house. The fruits are small and handsome, and the flowers have a pinkish tinge and are very fragrant. These plants will bloom and bear when not more than a foot high if the roots are somewhat confined or the plants not over-potted. Usually they will bloom the greater part of the year, but, like most hard-wooded plants, the best results are secured if they have a period of rest, as indicated above. The temperature for all oranges should be relatively low; that is, it should be the temperature of the intermediate house or one that will grow carnations, chrysanthemums, geraniums, and the like.

Literature.

There is much literature on the orange, a large part of it in the form of bulletins and reports. An authoritative general work on oranges is Risso and Poiteau, "Histoire et Culture des Oranges," Paris. On the oriental forms and histories of oranges, one should consult Bonavia, "The Cultivated Oranges and Lemons of India and Ceylon," London, 1890. The American books on the orange are as follows: Hume "Citrus Fruits and Their Culture;" Coit, "Citrus Fruits;" Garey, "Orange Culture in California;" Moore, "Treatise of Orange Culture in Florida, Louisiana and California;" Manville, "Practical Orange Culture: including the Culture of the Orange, Lemon, Lime, and other citrous fruits as grown in Florida;" Spalding, "The Orange: Its Culture in California;" also small books or pamphlets or reports

Orange-culture in Florida.

The Spanish occupation of Florida began with the landing of Ponce de Leon in 1513, and they maintained a more or less precarious hold upon the state, disputing possession with the English colonists to the northward, and with the aborigines, until the year 1821 (excepting the years 1763–1783), when it passed under the control of the United States. It was during the Spanish régime that oranges were first grown in Florida, and there is reason to believe that as early as the year 1600 the orange was fairly well established on the Florida peninsula.

As in the early days of orange-culture in Spain, the sour orange (*Citrus Aurantium*) was the fruit cultivated, so in Florida it is not unlikely that the earliest Spanish importations were of sour orange fruit from which seed was secured. At any rate, when the early English colonists made their homes in Florida, they found the sour orange much the more common, although some sweet orange groves were also found. One of the most noteworthy of these sweet orange groves was found in 1823 in Turnbull Hammock near Hawk's Park. It was from this grove that the old strains of oranges which made the Indian River famous came. The old sour orange groves were found mainly on the shores of lakes and rivers, where the fruit had been brought and consumed by the Indians and where the seeds, thrown aside by them, found a congenial soil for germination and growth. The trees were usually mixed with and protected by magnolia, live oak, and other hardwood forest growth. These natural sour orange groves were the foundation, in many instances, of important sweet orange plantings, particularly in the older orange districts in the central part of the state. In some cases, the sour orange trees were topworked where they stood; in others they were taken up, planted out in orchard form and then topworked. There is no orchard cultivation of the sour orange in the state at this time.

The earlier sweet orange groves in Florida were established near lakes and rivers because these afforded the only means of getting the fruit to market. These plantings were made almost entirely with seedling trees, and in spite of the ravages of mal-di-gomma and frost, in many regions they furnish a very large proportion of the crop at the present time. Nor is its quality open to question. In the early sixties there were many famous groves along the St. John's River, but it was not until the railroads opened up the state that the growing of citrous fruits took its place as Florida's most important horticultural industry.

Previous to the severe frost of 1894–5, much fruit was produced in northern Florida, but while some is still grown, the industry has been gradually moving southward, until now the larger part of the total crop comes from the southern part of the state.

Climate.

The Florida climate is usually marked in spring by a pronounced dry period which extends from the latter part of March or early April up to the beginning of the summer rains, which generally commence in June. During June, July, and August, the rainfall is uniform and heavy. The autumn months are fairly dry, while showers are intermittent during the winter season, with a very large proportion of days of bright sunshine. The annual average rainfall is 53 inches, most of which comes during the summer months.

Florida has been visited from time to time by severe cold waves. Among these, the most noteworthy were the ones which came in 1886 and in 1894–5. At the time of these cold waves, the orange industry was established in the more northerly counties of the state and consequently the damage was much more serious than would occur at the present time, owing to the opening up of the southern districts. The damage from cold waves in Florida has often been greatly increased because they were preceded by periods of high temperatures which caused sap movement in the trees. When entirely dormant, an orange tree is fairly hardy, while, in growth or when stirred from its dormant condition, it may be injured at comparatively high temperatures. This, however, is more or less true of other plants, though they do not respond so readily to variations in temperature. But in Florida, many fruit-trees and ornamentals entirely hardy much farther north have been injured at times because they were not completely dormant.

Soils.

Florida lands are generally grouped according to elevation and the growth of native timber or vegetation by which they are, or were, covered in a virgin state. Those commonly used for the cultivation of citrous fruits are high hammock, and low hammock, high pine and flat woods land.

High hammock lands are elevated, naturally well drained, and are covered with a native growth of evergreen hardwood and deciduous trees. Among these may be mentioned the live oak, hickory, magnolia, dogwood, and holly. They are well supplied with vegetable matter, the soil is comparatively rich, deep and well adapted for citrous fruit-culture.

2614. Mandarin, a kid-glove orange. Citrus nobilis var. deliciosa.

Low hammock lands (hammock is an Indian name for a hardwood forest) correspond in a large measure to the high hammock soils. They are not so well drained naturally. The native growth is of much the same character, but the sweet gum, live oak, and cabbage palmetto are more in evidence. Drainage requires careful attention, but the soil is rich in humus. The clearing and preparation of these low hammocks for planting is difficult and expensive, but the results in vigorous orange trees and crops of fine fruit leave little to be desired.

High pine land is well drained, elevated and often rolling. The native growth consists almost entirely of long-leaf or yellow pine with little or no undergrowth, the latter being replaced by wire-grass. Sometimes a few high-land willow oaks are found. These lands are frequently swept by fires, and consequently the humus-content is lower than would otherwise be the case. The subsoil may be sand, clay or loamy sand. They are not rich soils, but respond readily to good treatment and produce excellent oranges.

Flat woods land is also covered with long-leaf and other pines, but the elevation is much lower and the surface flat and level. Often there is a dense growth of saw palmetto. The subsoil may be clay, sand or hardpan. The better class of flat woods make good citrous soils, but those supporting a heavy growth of saw palmetto or with a hardpan subsoil are not considered good, and though sometimes used are usually avoided.

In the handling of Florida soils, the most important things to which attention should be given are drainage and the maintenance of the humus-content of the soil. The rainfall is heavy at times and provision must be made for the rapid elimination of surplus moisture, while the light character of the soil, high temperatures and moist condition assist in the rapid disintegration of the vegetable matter. A water table about 3 feet below the surface is desirable.

Stocks for citrous trees.

Intimately associated with the character of the soil is the kind of stock which should be used for the orchard. The seedling sweet orange as a foundation for a young orchard is a thing of the past and at this time only trees budded on stocks of different kinds are used.

The stocks more or less commonly used for orange trees in Florida are sour orange (*Citrus Aurantium*), rough lemon (form of *Citrus Limonia*), grapefruit (*Citrus grandis*) and trifoliata (*Poncirus trifoliata*). Each has its peculiar advantages for certain soils and climatic conditions.

No stock is more commonly used in the world's citrous regions than the sour orange. Trees propagated on it are long-lived, vigorous, and produce fruit of high quality. The stock itself is resistant to mal-di-gomma and some other similar diseases which affect other stocks. Wherever it can be used, it should be given preference. It is a congenial stock for all important varieties of oranges, the Satsuma alone excepted. This variety does not grow well upon it. The sour orange tree itself is more resistant to cold than the sweet oranges usually worked on it. It is adapted to low hammock, high hammock, flat woods and to high pine land soils where the latter are not too porous, open, and deficient in moisture. If fruit is to be held on the trees later than its season, or for late-maturing varieties, it has no superior.

2615. Satsuma orange.—Citrus nobilis var. unshiu. (×⅓)

Rough lemon stock produces more vigorous tree-growth than sour orange stock. The root-system is widespreading and rather shallow. It is much more tender than the sour orange and trees budded on it are not so cold-resistant. It is not desirable for early varieties as the fruit is not well filled and juicy, and fruit borne by trees budded on it cannot be held very much beyond its season without parting with its juice. It is adapted to conditions where a comparatively shallow root-system is advantageous and to very light sandy soils where a root-system of wide foraging range is necessary.

Grapefruit stock, used in a limited way, produces high quality fruit and is adapted to soils containing liberal amounts of moisture and with rather high water-tables. Where it can be used, it gives very satisfactory results. If the soil is underlaid with clay, close to the surface, so much the better. Grapefruit stock is entirely unsuited to dry open porous soils. In point of hardiness and resistance to cold, it ranks with rough lemon.

Poncirus (*Citrus*) *trifoliata*, commonly referred to as trifoliata stock, is the hardiest citrous stock now in general use in America. The tree itself will stand 22° F. at least and it imparts a certain measure of its own hardiness to the orange that is worked on it. This, in the main, is brought about by its very dormant character. In this combination is a noteworthy example of an evergreen tree budded on a deciduous one. Trees budded upon it do not start into growth so readily nor so early in spring. The fruit produced on this stock is smooth, thin-skinned, very juicy, and of high quality even with the very first crops. *Poncirus trifoliata* stock is adapted to clay soils, loamy or sandy soils with clay close to the surface and to alluvial soils. It requires a uniform and goodly supply of moisture. In Florida it is used for plantings of Satsuma and other oranges in the northern and western parts of the state.

Propagation and the seed-bed.

The seed-bed in which citrous seedlings are grown is carefully prepared in advance by liming and by applying commercial fertilizers. The soil is well and deeply broken, pulverized and raked free of all roots and trash. Irrigation is usually provided, though not always necessary and may be dispensed with on moister soils.

Seeds of sour orange, rough lemon, grapefruit and trifoliata are extracted by cutting through the rind of the fruit, twisting the halves apart and squeezing out the pulp and seed into a vessel. They are then washed free from pulp and dried off slightly in the sun, just enough to remove such moisture as may remain on the seed-coats. Sometimes the fruits are allowed to decay partially, when the seed is removed by macerating in water and floating off the pulp, rind, and other refuse.

Citrous seeds will not stand drying and remain viable. If they are dried, the cotyledons separate and they will not germinate. Seeds may be kept several weeks, or even months, by drying off on the outside and packing in pulverized charcoal in tight receptacles. It is best, however, to plant sour orange, rough lemon, and grapefruit seeds immediately after they are extracted in December and January. Trifoliata seed is best extracted in September and October and planted at once in soil containing considerable moisture, yet well drained. Frosts are very injurious to young citrous seedlings of all kinds except trifoliata. If frozen off when 1 or 2 inches in height, they are killed out, but trifoliata develops shoots from buds lower down on the stem and the stand is but little injured.

Seeds are planted much as garden beans are planted, in rows 2 feet apart. Frequent cultivation is given from the time the plants come through the soil, and fertilizers rich in nitrogen are applied from time to time as required by the seedlings. Damping-off sometimes causes serious losses in seed-beds, but may be prevented by spraying frequently with bordeaux mixture and by keeping the soil about the plantlets dry and well pulverized on top.

Seedlings are transplanted when one year old and 6 to 15 inches in height or when two years old and 15 to 24 inches in height. Preference is given to the larger seedlings, as they are easier to handle and care for under field conditions. The nursery rows are spaced 4 feet apart, the plants about 1 foot apart in the rows. A row is left out here and there at convenient distances apart, making an 8-foot wagon passage. About 10,000 seedlings are set on an acre of ground.

The seedlings are grown from one to two seasons in the nursery, when they are ready for budding. While citrous trees may be propagated in many different ways, budding alone is resorted to in nursery practice in

Florida. By far the greater number of trees are dormant budded, the buds being inserted by the ordinary inverted shield method, the cross cuts being made at the bottom of the downward incisions and the buds shoved up from below. Wrapping is usually done with strips of waxed cloth. These are allowed to remain on from ten days to three weeks, depending upon weather conditions. Frequently, in the colder sections, these dormant buds are banked with earth, using a plow and a celery-hiller, to protect them against possible frost-injury in winter. In spring, the seedling tops are cut off and a stake driven beside each bud, to which it is tied as it grows. These stakes (4 feet long and ¾ inch square, made of cypress) insure straight trunks on the young trees and prevent the buds from being broken off when young and succulent. Careful attention is given to keep off all sprouts which come out on the stock and on the bud growth too low down. The work of sprouting and tying requires each bud to be handled five or six times by competent workmen, during the summer growing season. This adds greatly to the expense, but is necessary in the production of quality stock. At about 30 inches, the buds are topped and allowed to branch. Good buds of one season's growth will caliper ½ to ⅞ inch, 2 inches above where the buds were inserted. Usually the buds are placed rather close to the ground.

2616. Compound leaf of orange, with only one leaflet.

One-year buds are used by many planters, but two- and three-year buds are preferred by many, particularly among the older planters. These latter trees caliper from 1 to 2 inches, depending upon the variety and the stock on which they are grown.

Planting.

Opinions vary considerably as to the best distances at which to set orange trees in Florida, but 25 by 25 feet may be taken as a reasonable distance for standard sorts, or sixty-nine trees to the acre. Some prefer to set trees farther apart one way than the other, as 20 by 30 feet. Satsuma is usually planted 20 by 20 feet. The rectangular system is used almost entirely.

Land is prepared for planting, by plowing deeply and pulverizing thoroughly. Nearly all Florida soils are greatly benefited by applications of lime, and by having a cover-crop of some kind grown on them during the summer and turned under the autumn before planting. This increases the humus-content of the soil and leaves it in the best possible condition for the trees.

Sometimes orange trees are planted out during the early summer months, just after the summer rains set in; but by far the best season for planting the trees is during the winter months of December, January, and February. Planting should not be delayed too late, as best results are secured if the trees are established in advance of the dry spring period, which usually begins in March.

In the actual setting of the trees, the chief points to be observed are (1) that the roots be not exposed, (2) that the trees be set at the same depth as they grew in the nursery row, (3) that the soil, naturally rather open, be well packed and firmed about the roots. Balled trees are not used in Florida on account of the character of the soil, nor are they considered necessary. Water at time of planting is advantageous, as it helps to settle and pack the soil about the roots, and at times there is an actual lack of moisture to be supplied. Surface soil is used in filling in about the roots and some commercial fertilizer is often thoroughly mixed with it, from a half-pound to a pound, depending upon the size of the trees. The use of stable manure is not advisable.

Cultivation.

Clean cultivation throughout the year, though at one time attempted in Florida, is a practice which has entirely disappeared. It did not take many years to demonstrate that it was a failure, because the basic necessity of maintaining and increasing the humus-content of the soil was not taken into consideration. At the present time, two systems of cultivation are in use: (1) the usual system of clean cultivation in spring and summer, followed by a cover-crop; (2) a system of non-cultivation, under which the vegetation which covers the soil is cut from time to time and allowed to mulch the surface.

By far the greater number of plantings is handled by the first system. Under the clean-culture-cover-crop or the 4-C system, cultivation begins in early spring as soon as danger of frost is past and the trees have started into growth, and is continued until about the middle of June or the beginning of the summer rainy season. During this period the grove is cultivated shallowly once every ten days or thereabouts, and a dust mulch is constantly preserved to prevent the escape of moisture from the soil. When cultivation ceases in June, a cover-crop is either planted or allowed to come on voluntarily, consisting of cowpeas, velvet beans, beggarweed or native weeds and grasses. If the growth of this crop is so rank as to make it difficult to handle in fall, it is cut with a mowing machine and allowed to remain on the ground for some time before incorporating in the soil. In autumn the cover-crop is either plowed under or cut into the soil with a disc-harrow. It is advisable to have the ground bare and free from vegetation in winter as a safeguard against fires, and when the soil is bare, the trees suffer much less from cold than when the soil surrounding them is covered by a dense mat of dead or living vegetation. On heavier soils the cover-crop may be plowed under, but on lighter soils best results are secured by disposing of it with disc-harrow, cutting it over several times if necessary. In Florida, it is not advisable to incorporate a green cover-crop with the soil. The advantage of the 4-C system is that clean culture during the spring months conserves soil-moisture when most needed, while the cover-crop during the summer helps to take care of the excess supplied by the rains. At the same time, vegetable matter is added. In handling young groves, the plan is often followed of cultivating the soil in the narrow strip along the tree rows throughout practically the whole season and growing a cover-crop on the middles. The implements com-

2617. Otaheite orange in a pot.—Citrus taitensis.

monly used for grove-cultivation in Florida are the plow, disc-harrow, and Acme harrow.

The system of non-cultivation is followed on certain lowlands, on light soils, and, in general, where the character of the soil or subsoil makes it inadvisable to follow the 4-C system. It has also given good results under conditions where the 4-C system might be used, and is followed because less expensive and the trees thrive under it. The plan is to give no cultivation at all, except when the trees are young, only to hoe the weeds and grass immediately surrounding the trees. This same end is secured in many cases by mulching heavily with weeds, grass, leaves or trash of any sort. From time to time, the mower is used to cut down the growth of vegetation. It is allowed to remain where it falls. There is no question but that fine fruit is produced under certain conditions by this system, but much depends upon the character of the soil and the moisture available.

2618. Frost protection. Movable shed with cloth sides and board top, for protecting young trees. It is not used commercially.

Cover-crops.

The plants commonly used in Florida for cover-crops are beggarweed, cowpeas, velvet bean and its relatives, and native weeds and grasses. Cowpeas and velvet beans are better adapted for new soils, those only recently brought into cultivation. These crops are also very valuable for preparing soils for planting. A good stand of cowpeas may be secured on almost any Florida citrous soil if planted at the right season. But the best cover-crop for Florida orange groves is beggarweed, either alone or combined, as it most usually is, with a number of other native plants. These latter appear without the necessity of seeding them.

Beggarweed is a strong, erect annual legume, a native of Florida, and thoroughly adapted to all parts of the state. When standing apart, with plenty of room for growth, it is a much-branched plant, but, when closely planted, it produces small straight stems. Nitrogen tubercles are produced in abundance on its deep roots. At the end of its season's growth, a good covering of partially decayed foliage covers the ground. Often it is best to cut it once during the season to prevent its getting too rank and heavy. If cut at the blossoming season, a second crop will come on from the stubble. As much as one to two tons of stems and leaves may be produced to an acre. From five to ten pounds of seed are sown to the acre in April and May, broadcasted and harrowed into the soil. After the crop has become well established, it reseeds itself from year to year and cultivation may be continued up to the rainy season without interfering with the crop. It will come on as soon as cultivation ceases. If it be deemed advisable to stop the growth of beggarweed in a grove, as is sometimes the case if there is too much nitrogen in the soil, it may be accomplished by cutting frequently to prevent seeding and by continuing cultivation later into the summer.

Pruning.

The general plan followed in Florida orange-growing is to give the trees but little pruning. Beyond shaping up the trees, mostly done while they are young, little is done except to remove dead, injured or diseased branches. The type of trees developed is low-headed, symmetrical, and spreading. The low-headed tree is almost the only form seen in the younger groves and as the advantages in shading the ground and the tree-trunks, in spraying and in harvesting, are all in its favor, it is not likely to be displaced.

Fertilizers.

In no citrous region have the problems connected with the fertilizing of orange groves received more attention nor has a greater amount of definite knowledge pertaining to this difficult problem been secured than in Florida. The kind and quantity of fertilizer used has a pronounced influence, not only upon the quantity and quality of fruit, but upon the growth, health and longevity of the trees, and it has taken many years to determine the value of different materials in the fertilizers applied. Much remains to be found out, but a good start has at least been made.

The leguminous cover-crops referred to, when rightly handled, supply a large part of the necessary nitrogen, but the fertilizers applied to orange groves in Florida are drawn almost entirely from commercial sources. Potash is used largely in the forms of high- and low-grade sulfate of potash; phosphoric acid is secured from bones and phosphate rock, while nitrogen is procured from nitrate of soda, sulfate of ammonia, and from organic sources such as blood, tankage, cottonseed-meal, castor pomace, and the like. Much care must be exercised in the use of nitrogen in organic combinations because they are prone to induce "die back," a physiological disease characterized by the exudation of gum on twigs, leaves, and fruit. The several materials entering into the composition of fertilizers, as sulfate of potash, sulfate of ammonia, and acid phosphate (for example) may be purchased separately and mixed by the grower in proper proportions, but more usually they are mixed by the fertilizer manufacturers and sold as complete fertilizers.

Fertilizers for nursery trees, and plantings which have not reached bearing age, contain about 6 per cent phosphoric acid, 4 per cent ammonia, and 6 per cent potash, while for bearing trees one containing approximately 8 per cent phosphoric acid, 4 per cent ammonia, and 10 or 12 per cent potash is commonly used. These percentages are of course not absolute, as the exact composition must be governed by the character of the soil, the condition or requirements of the trees, and crops. Growers watch the behavior of their trees carefully and are governed in the use of fertilizers by their general appearance.

2619. A slat shed formerly used to some extent for the protection of orange plantings in Florida, but now discarded.

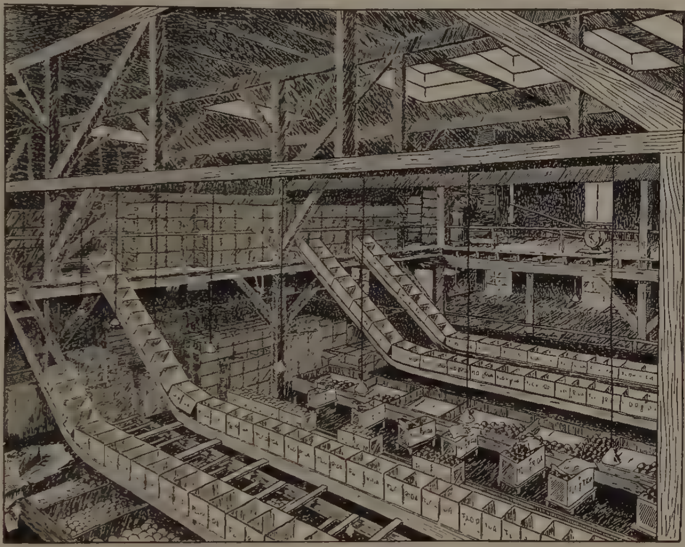
Lime is very generally deficient in Florida citrous soils and the trees and fruit are much benefited by applications of ground limestone, broadcasted over the surface at the rate of about two tons to the acre.

The general tendency in the use of commercial fertilizers is to make frequent applications of small amounts, thereby preventing loss from leaching. Applications, by many growers, are made in February, April, June, and September. The composition of these applications is often varied, giving larger amounts of nitrogen in spring and larger proportions of potash in autumn. Young orange trees are fertilized roughly on a basis of one pound to two pounds for each year of age and bearing trees according to their size and crop indications; sometimes as much as thirty or even fifty pounds a tree in the year is applied in the several applications to the latter. These amounts may even be exceeded if the crop in sight justifies.

In fertilizing young trees, the fertilizer is scattered in a band 2 or 3 feet wide, beginning back 6 to 12 inches from the trunk. As they become older, the fertilizer is spread out toward the ends of the branches and in old orchards or groves it is broadcasted over the whole surface, as the roots have made their way into all parts of the soil. After each application of fertilizer the ground is usually cultivated.

Insects and diseases.

The insects which cause most damage in Florida orange groves are the white-fly (*Aleyrodes citri*), scale insects of different kinds, and the rust mite. In insect-control, fumigation has been carefully tried out but has not met with general favor, and by most growers spraying is considered more satisfactory and practicable. Against the white-fly and scale insects, miscible oil and whale-oil soap sprays are generally used; and against the rust mite, sulfur in some form is effective. For the control of white-fly and scales, most of the spraying is done in the winter dormant season, one thorough application usually giving satisfactory results. Spraying for rust mite is done during the summer months as it injures the skin of the growing fruits, and three or more sprayings are generally necessary. In Florida, beneficial entomogenous fungi are very effective in holding scale insects and white-fly in control.



2620. A Florida orange packing-house.

Among the fungous diseases the most injurious are melanose with which is associated the stem-end-rot, and anthracnose or wither-tip. These may be handled by careful attention to grove sanitation, removing diseased fruit, pruning out dead and injured wood, and by spraying with bordeaux mixture. "Die-back," a physiological trouble to which reference has already been made, may be corrected by changing the method of cultivation and the fertilizer used. The common method is to discontinue cultivation entirely, and use no fertilizers or those drawn only from inorganic sources and rich in potash.

Citrus Canker, a bacterial disease caused by *Pseudomonas citri* (see also page 2375) has gained a foothold in Florida and threatens serious injury to the citrus industry. The authorities are meeting with success in their determined efforts to stamp it out. No attempts have been made at control, the method of handling it being to burn the affected trees where they stand.

Frost protection.

Within recent years much attention has been given to the protection of orange groves against cold. Many different methods have been tried, but protection by means of sheds, tents and the like has been abandoned except for strictly amateur purposes (Figs. 2618, 2619). The trees were not fruitful under the artificial conditions created, or the methods were too costly. In the more exposed sections, the trees are still banked with clean earth, sufficiently high to afford protection to the bud unions. But the chief method of protection is by firing with small wood-fires or with oil-heaters.

Harvesting and marketing.

The season for Florida oranges extends from the latter part of October until June. This is divided into two parts by the Christmas holidays. At that time but little is shipped. Unfortunately, it has been the custom to ship fruit that is green and unfit for consumption. Attempts have been made to correct this mistake by laws and these have helped greatly.

Perhaps the greatest change in harvesting and marketing in the last two decades has been in the disappearance of the small individual packing-house. Most orange groves in Florida are small, 10 to 25 acres, and formerly nearly every owner had his own packing-house and picked, packed, and shipped his own fruit under his own brand. Now the marketing of the crop is in the hands of the Florida Citrus Exchange, or of individuals or companies operating on a large scale, and the fruit, in large quantities, is handled through centrally located packing-houses equipped with every convenience for the rapid and economical preparation of the fruit for market (Fig. 2620). This noteworthy change has brought about a great improvement in the methods of handling and the uniformity of the pack. Every detail of picking, hauling, handling, packing, and shipping has been carefully investigated and many improvements have been introduced. As a result, the value of the Florida orange in the markets has been greatly increased by the care taken in handling it.

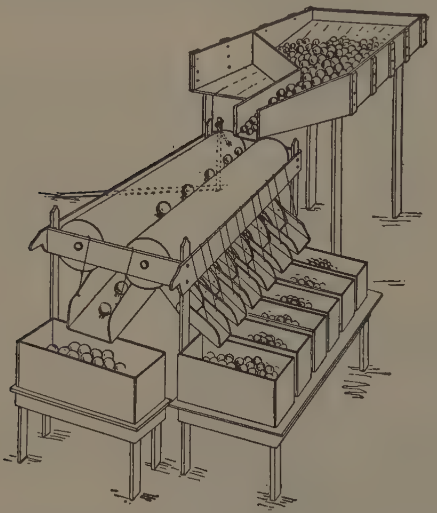
The standard Florida orange box, the size of which is fixed by state law, contains two compartments, each 12 by 12 by 12 inches, or 2 cubic feet of fruit. Oranges of the mandarin group are put up in half-boxes, two of which are fastened together for shipment, known as a "strap." The fruit is arranged in the box according to definite diagrams for each size.

The Florida orange crop has been gradually increasing. In the season of 1914–1915, approximately 7,000,000 boxes were produced.

Varieties.

Of the mandarin group, the varieties planted are Satsuma (in the northern part of the state), Dancy, Tangerine, and King. The Dancy originated in Florida; the other two are introductions.

A great many varieties of sweet oranges have originated in Florida as noteworthy seedlings in different groves. Perhaps in no fruit-growing region of America was the amateur spirit more strongly developed or was more interest taken in the merits of different varieties. Formerly a great many different sorts were planted, but gradually the most of these have been eliminated until only a few remain. Of these the most important, arranged according to season of ripening, are, Parson Brown, Homosassa, Pineapple, Ruby, Valencia Late (Hart's Tardiff, Hart's Late), and a recent introduction, Lue Gim-Gong, remarkable because of its late-keeping qualities. Of this list, all originated in Florida except Ruby and Valencia. These are introductions from Europe.



2621. A sizer or grader for oranges. (Wester.)

H. Harold Hume.

Orange-culture in Louisiana.

From the early settlement of Louisiana to the present day, orange-culture has received most attention in the lower Mississippi delta, but for several years past, the other coastal lands have produced fruit in some quantity, and more recently, plantings of the hardy Satsuma variety in particular have been made in the interior sections of the southern half of the state. Originally, the seeds of sweet oranges were planted and the young trees transplanted in and around the home yards and gardens; and, to a slight extent, this method of growing trees is practised yet by individuals. No extensive groves were grown until after the close of the Civil War. At first, groves of these seedling trees only were planted and they proved exceedingly profitable up to the very cold spell of 1895, which destroyed nearly every one in the state. Another freezing calamity, occurring in February, 1899, utterly killed every tree to the ground.

In the meantime, extensive experiments had been made in budding the choice varieties of sweet oranges on various kinds of stocks, and many of the trials demonstrated the power of resisting moderate freezes by certain kinds of root-growth, notably the *Poncirus trifoliata*. Accordingly, many of the old groves and numbers of new ones were planted in budded stocks, using the buds of selected trees of sweet oranges and establishing them upon the *Poncirus trifoliata*. The success of this method also led to the growing of grapefruit or pomelo, mandarin or tangerine, and Satsuma and kumquat upon the trifoliata stock.

Budded stock has thus almost entirely superseded sweet seedlings. The sour orange, the bitter-sweet orange, the rough lemons, the grapefruit or pomelo, and the *Poncirus trifoliata* have all been used successfully as stock for the sweet orange. Meanwhile, with the introduction of the hardy Japanese varieties, including the Satsuma, mandarin or tangerine, these were also budded upon various kinds of stock. In 1895, when the temperature fell to 15° F. in New Orleans, the only trees able to survive this cold were found to consist of the combination of the hardy Japanese varieties budded upon the *Poncirus trifoliata*. This experience caused the adoption of the trifoliata as the chief stock for future groves. Therefore, nearly all of the groves planted since that time have been made with this stock.

Account must be taken of a frost limit beyond which this combination succumbs to the effects. Such results were evidenced by the unprecedented freeze of February, 1899, which practically wiped out every kind of citrous growth. Since that time, orange-growing made very slow progress for a long time, but gradually the ground was replanted and the industry expanded until plantings are now scattered over most of the southern half of the state, and, at present, many large groves are to be found. Under suitable attention, the industry has brought profitable returns, and the fame of the Louisiana Sweet, also called "creole orange," is widely known for its excellence. These names apply to a great variety of strains, but all are of a type originally introduced from southern Europe and developed by select cultivation. The budded trees bear early and yield in three to five years after being transplanted in the grove. The city of New Orleans furnishes a home market for most of the crop that is raised in the delta, although large shipments are made to northern points. Local consumption generally absorbs the supply grown in other sections.

The Louisiana orange matures ahead of the Florida fruit and is also ready before the California crop ripens, and, therefore, reaches the market when, on account of scarcity, good prices prevail. These facts, coupled with the readily productive soil, seldom requiring any fertilizer, and the abundant rainfall, dispensing with irrigation, make orange-culture attractive in Louisiana.

Frost protection.

The most serious drawback is an occasional cold blast from the North in winter or early spring, which drives Gulfward, overcoming the usually balmy weather and temporarily chilling the growth. At rare intervals, such as have been mentioned, a blizzard occurs so intense as to kill the trees outright. How to protect groves against these destructive frosts is an important matter with the orange-growers. Flooding the orchard with water drawn from the adjacent river or bayou, upon the approach of a freeze, has been practised upon a large scale without complete success. The use of oil-burning orchard-heaters, or smudge-pots, comes nearest to solving the problem, and some enterprising growers are equipped with outfits. Other producers sometimes resort to building smudge-fires on the ground. The practice of banking the trees by piling the soil around the trunk to a height of a few feet more or less (Fig. 2622), on the approach of a freezing spell whose intensity and time of coming are usually predicted by the government weather service, is very largely adopted as the next best economical protection against excessive cold. This banking retains vitality in the main trunk, and while the outer limbs may be killed, young shoots will start from the tree when the soil is removed and spring advances. This practice, therefore, gives only partial protection. Should the tree be frozen so as virtually to cause the death of the growth, new shoots from the protected trunk will soon appear, and in a year or two the tree resumes shape and becomes ready to bear a crop. Although the yield is lost for the ensuing interval, yet, by skilful care, the grower is enabled to secure a renewed orchard quickly. A trial with shelters built to cover the trees has shown them to be very expensive and, further, caused shortage of yield by shading the growth in summer.

Insects and diseases.

Unfortunately, not enough attention has been given toward preventing the introduction of pests, both insects and diseases, nor to accomplish their control after becoming established. Consequently, through carelessness and neglect principally, the pests have spread nearly everywhere and made many trees unproductive. The leading growers have been compelled to fight these enemies in order to produce clean fruit in sufficient quantity to make commercial growing pay. Added to the cost of spraying groves regularly, some packers clean and polish their fruit, which process involves an investment in a properly equipped plant and further labor for the purpose. The chief insect foes are the citrus white-fly (*Aleyrodes citri*), the purple scale (*Lepidosaphes beckii*), Glover's or long scale (*Lepidosaphes gloverii*), and the chaff scale (*Parlatoria pergandii*). Recently, the cottony cushion or fluted scale (*Icerya purchasi*) has appeared to a limited extent in one locality. With the advent of the Argentine ant (*Iridomyrmex humilis*), the attendance of this pest upon scale insects has greatly increased the abundance of the latter and complicated the problem of their control. Russeting of fruit, due to infestation by mites, occurs in some places.

Following the discovery of the canker disease in 1914, many thousands of nursery stock plants and numbers of older trees were entirely destroyed by cutting and burning in efforts to eradicate this incurable evil. The danger of this menace has brought the growers to a realization of the need of having adequate state protective measures provided for the industry. Awakening to the necessity of aiding in the development of citrous culture, the General Assembly in special session during 1915 appropriated $5,000 for eradication of canker, other diseases, and pests. This recognition, however, gives some hope that sufficient provision will be made by the state in the near future to bring it to the fore rank in horticultural prosperity through the suppression of enemies and the promotion of all fitting lines of fruit-growing. The leading orange culturists have effected an organization called the Louisiana Citrus Growers' Association, whose object is to protect their interests against natural foes.

Propagation.

The propagation of oranges is effected directly from seed and from buds. Budding is done at any time of the year from early spring to late fall. When performed in the fall, the buds remain dormant through the winter. The various stocks have particular merits for special soils and other conditions, and several kinds are used, as already said; but when the chief obstacle to successful orange-culture is cold, all other considerations must be dispensed with and only the most resistant stocks used. These stocks, are, first, *Poncirus trifoliata*, and, second, sour orange. The latter, however, is not very well adapted to the climate much north of the latitude of New Orleans. Hence, nearly all Louisiana groves have been propagated on these two stocks, a large part being on the former.

Planting a grove is always preceded by a nursery, and though home-grown stock is being produced in extensive quantities, most trees for planting are yet brought from outside of the state. The nursery is started by planting the seed of the *Poncirus trifoliata* or sour orange. When the shoots are one to two years old, they are shield-budded with buds from selected varieties, or rarely grafted to obtain the desired kind of top-growth. One year later, as a rule, the combined growth is large enough to be planted out in groves.

Soil and fertilizer.

The soil selected for groves is first thoroughly prepared and pulverized, and needs to be well drained. The trees are planted at intervals of 12 to 20 feet (sometime more or less) apart both ways, and the grove is cultivated until the trees become large enough to shade the ground. After that period, only the weeds and bushes are kept down. Very early or late cultivation of trees is usually discouraged, as having a tendency to induce a too luxuriant, sappy growth, which may be injured by subsequent frosts. The cultivation is usually performed with light plows or suitable cultivators.

A fertilizer containing fifty pounds of nitrogen, fifty pounds potash, and twenty-five pounds phosphoric acid to an acre is the one usually recommended in this state. Of course, special requirements should be considered, depending on the age of trees. Sometimes on rich soils, only a dressing of lime or bone-meal is needed. Truck or leguminous crops may be advantageously grown between the rows of young trees.

Yield.

In three years after a grove is planted, the trees should begin to bear, increasing their products every year thereafter, and becoming profitable at five to six years of growth. When ripe, the fruit is carefully gathered by hand with clippers, using ladders to reach the high limbs, then assorted and packed in boxes, and shipped to market, generally in New Orleans.

Some idea of the status of production may be obtained from figures secured in 1915 by the entomologist in charge of Tropical and Subtropical Fruit Insect Investigations of the United States Department of Agriculture, having a station in New Orleans. According to the data applying to 361 groves, the yield is classified proportionately as follows: sweet, 63 per cent; mandarin, 20 per cent; tangerine, 5 per cent; navel, 7 per cent; pomelo, 3 per cent; Satsuma, 1 per cent; and Valencia, kumquat and miscellaneous, 1 per cent. On an average, 108 trees are planted to the acre. In Plaquemines, St. Bernard and Cameron parishes, the number of bearing trees amounted to 270,505, while 73,285 trees were found that had not yet borne any fruit. A large part of a tract of 7,000 acres, located near the city of New Orleans, has been planted in groves, and the company is proceeding in preparations to cover the whole area with one vast orchard.

The marketable crop for 1914 was placed at 275,000 boxes by a well-posted commission merchant of New Orleans. To quote his experience during the past twenty years in marketing the fruit, he says: "When my first visits were made to groves, the growers were not disposed to deal with commission merchants, owing to previous unfair treatment, and the industry was entirely without organization. The growers then had no knowledge of the value of their oranges, or of how to market them. They sold their fruit to speculators, who bought it on the trees, for any price that they chose to give for the crop. These speculators' manner of handling the fruit was very crude. They pulled the oranges from the trees without the use of clippers, threw them into buckets, dumped them into boxes, hauled them to the

2622. The banking of orange trees on the Mississippi delta.

boats which sailed for New Orleans, and, in this unattractive fashion, offered the fruit for market in a bruised and decaying state. After educating the growers, they began picking carefully, but without any method of grading or sizing. The first packing efforts were made without using wrapping-paper, though later they were taught how to wrap the fruit. Many years passed, however, before our leading growers were induced to install modern graders, cleaners and polishers. The growers are now using labeled paper and printed boxes, and compete in the principal markets, and have been doing so for the past several seasons, with the best oranges grown elsewhere.

"Louisiana oranges are of the highest quality, being thin-skinned, sweet, juicy, and have a delicious flavor that is not found in any other orange. A number of markets take them at higher net prices to the growers than are obtained for either Florida or California oranges. A vastly greater quantity than we now raise could be handled to equally good advantage. The opportunity to market so many more than are now grown should be an inducement to an enormously increased acreage.

"Any number of growers who have shipped from 1,000 to 10,000 boxes of oranges are willing to testify that results during the past five years have been from $1.25 to $1.75 per box net on the trees. These prices included culls and all varieties of oranges which they grew. The production per tree compares favorably with other citrous fruit-growing sections. Our real industry, however, lies in our commercial varieties known as the Louisiana Sweet orange. This fruit comes on the market about the first of October, and shipments continue until the first of January. The season could be extended, but, on account of our limited crops, we find no necessity to hold the fruit any longer. We grow successfully the Satsuma, which begins to move in the latter part of September, and shipments are madeuntil the end of October. Then follows our sweet high-grade mandarin; these first appear in October and last until the middle of November, sometimes extending a month longer. The tangerine starts to move about the middle of November and continues until the latter part of December. The navel orange is also grown very successfully, the only drawback being that they grow too large, as the market is limited for extra-large sizes. Valencias are ready for market in February and the season extends until March; they usually command $1 per box more than Louisiana Sweets for the reason that the bulk of the sweet crop is then sold out, thus leaving a bare market. Grapefruit is perfectly adapted to our soil and climate. It is a large producer and of a quality equal, if not superior, to that grown elsewhere. Our prices have been very high, on account of which our growers are generally increasing their acreage of this fruit tree."

E. S. Tucker.†

Orange-culture in California.

Orange seeds were brought into California by the Jesuit missionaries who planted the first orchard at San Gabriel Mission in 1804. The success of these trees so impressed William Wolfskill, a Kentucky trapper of German blood, that he planted the first commercial orange orchard in 1841 on the ground now occupied by the Arcade Passenger Station of the Southern Pacific Railway in the city of Los Angeles. Wolfskill was highly successful and gradually enlarged his orchard of seedling trees from 2 to 70 acres. It was he who, in 1877, shipped the first full carload of oranges across the Rocky Mountains to eastern markets.

Thomas A. Garey, of Los Angeles, established the first citrous nursery in 1865 and by propagating trees and introducing new varieties, played a prominent part in establishing the industry.

Extensive commercial development of orange-culture may be said to have begun with the completion of the Southern Pacific Railroad's connections with the East in 1876. Three years later, the exhibition of the first fruits of the Washington Navel orange at Riverside gave another impetus to citrous planting, but the greatest development came with the completion of the Santa Fe's competing line of railroad which was opened about 1885.

The strong demand for California oranges in the eastern markets and the high prices received by some, brought on a period of frenzied planting and speculation which culminated in 1882–1883, when drought, frost, scale insects, and the lack of a coherent marketing organization, conspired rudely to awaken from their golden dreams many who had rushed into the business with insufficient knowledge and capital to weather a period of depression. Since 1890, expansion has been rapid but conservative; better distribution and increased consumption have taken care of the increased production. At present (1915) production is increasing much more rapidly than consumption. The growth in production may best be shown by the shipments for the past twenty-four years:

California Citrous Shipments.
(Including all citrous fruits.)

Season	Carloads	Season	Carloads
1890–91	4,016	1902–03	23,871
1891–92	4,400	1903–04	29,399
1892–93	5,871	1904–05	31,422
1893–94	5,022	1905–06	27,610
1894–95	7,575	1906–07	29,820
1895–96	6,915	1907–08	32,729
1896–97	7,350	1908–09	40,592
1897–98	15,400	1909–10	32,648
1898–99	10,875	1910–11	46,394
1899–00	18,400	1911–12	40,673
1900–01	24,900	1912–13	18,960
1901–02	19,180	1913–14	48,548

The chief factors which have influenced the growth of the industry are: (1) The very favorable climatic and soil conditions. (2) The building of the railroads. (3) The great success of the Washington Navel variety as a regular and heavy bearer, a good shipper, and a splendid seller. (4) The protective duties imposed upon imported citrous fruits by the United States Congress. These duties have been continuously in force since July 4, 1789, although they have been changed in amount nineteen times during that period. (5) The marked enterprise of the persons engaged in the business. The California citrous business is peculiar in that the persons who have made it are, in so many cases, retired business or professional men from the East and North who, having lost their health in the acquisition of wealth, have bought and developed citrous properties, thus bringing into the industry much-needed capital, commercial ability, and business habits. (6) Coöperative packing and marketing. By this means a uniform standard pack has been established, better distribution secured, and, by uniting their strength, the growers have been able to secure from the railroads many valuable concessions. (7) The introduction of the Australian lady-bird beetle, *Novius cardinalis*, and its control of the cottony cushion scale. (8) The development of the method of refrigeration in transit. (9) Rigid inspection and quarantine methods against injurious insect pests and diseases. By this means the state has so far been kept free from the Mexican orange maggot, the Mediterranean fruit-fly, and many other damaging pests, such as the citrus canker. (10) Scientific investigations and research by the United States Department of Agriculture, the State University Agricultural Experiment Station, and the State Commission of Horticulture. (11) The great advertising activities by the Chambers of Commerce of the various cities and towns.

It is estimated that in 1915 the California citrous industry represents an investment of $200,000,000 and gives continuous employment to the equivalent of 40,000 persons. Not less than 200,000 acres were devoted to citrous fruits at the end of 1914.

The orange-producing lands of California are scattered from San Diego to Shasta County, a north-and-south distance of 450 miles. It is a peculiar fact that there are orange orchards in California in the same latitude with New York City; Peoria, Illinois; Lincoln, Nebraska; and Salt Lake City, Utah. This is made possible by the peculiar topography of the state whereby the mountain ranges are so arranged that the cold winds of the North are shut out, and the warm southwesterly breezes from the Pacific are admitted. The great interior valleys, such as the Sacramento, San Joaquin and Imperial, are very hot and dry. The chief citrous areas of these valleys are situated on the foothills about their rims. West and south of the Coast Range, the fogs and moist ocean breezes protect, to an extent, from sudden fluctuations in temperature, and orange orchards extend from the foothills well out upon the valley floor. The factors which determine orange areas are: frequency of frosts, water-supply, transportation, and soil conditions. The greatest and most productive area embraces the country around Los Angeles, Riverside, Redlands, Corona, Orange and Santa Ana. The second area in importance is the Porterville section in Tulare County. Other important areas are in San Diego, Santa Barbara, Ventura, Kern, Fresno, Sacramento, Yuba, and Butte counties. Large extensions are now under way in Ventura, Los Angeles, Tulare, Fresno, Glenn, Sacramento and Tehama counties. On account of the higher temperatures, the interior valley oranges ripen much earlier than those grown near the coast. As some of these valley orchards lie far to the north of the coast country orchards, the unusual procedure of shipping early ripening fruits southward to market is accounted for.

Cultivation.

Almost all the old seedling orchards of early days have given place to budded trees. Several kinds of stocks are used. The most popular root at present is the Florida sour orange, because it is better suited to heavy lands and is markedly resistant to gum disease and foot-rot. Sweet orange root is desirable on light well-aërated soils. Grapefruit root is being increasingly used and is especially satisfactory on desert soils of a granitic nature. The use of China lemon root has been discontinued entirely. The rough lemon and trifoliata roots are little used, as they very rarely show any advantage over the sour or pomelo, and in many cases suffer in comparison with them.

Seeds are usually planted under the partial shade of a lath-house. They are covered with an inch of sterile sand and watered with great care in order to prevent serious loss from damping-off fungi. After a year in the lath-house, the seedlings are transplanted into the field 12 inches apart in rows 4 feet apart. After a year's growth, they are budded from 2 to 6 inches from the ground. After the bud has set, the top is cut away and the young shoot trained to a lath stake and headed at about 33 inches. Budding is done both in the fall and in the spring and early summer. Some of the more rapid-growing trees will be large enough to set in orchard form at one year from the bud, but some will require two years. Often the slower-growing trees are the more desirable, having been budded from wood with heavy fruiting tendencies. In fact, a pair of calipers is a poor gauge of the value of an orange tree. Many fine large nursery trees produce but little fruit in after years. The selection of buds is a very important matter. Oranges vary and sport much more commonly than apples or pears and the greatest care and eternal vigilance is necessary in order to keep the nurseries free from undesirable sports. The worthless "Australian" or "hobo" trees which make up such a shockingly large proportion of many orchards are the result of ignorance or carelessness in selecting buds on the part of nurserymen whose only concern is to sell nursery stock.

Citrous nursery trees are usually dug and transported with a twenty- to forty-pound ball of earth about the roots inclosed in burlap. When set out, the cords are cut and the corners turned down but the sack is not removed, inasmuch as it quickly decays in the soil. Orange trees will grow just as well when dug with bare roots as when balled, provided the sun and dry desert air are not allowed to touch the moist roots even for a few minutes. There is the greatest difficulty in impressing laborers with the importance of this danger, which has led to the custom of balling trees and paying transportation charges on the extra soil as a precautionary measure. Balled trees retain their leaves, while bare-root trees have the leaves removed when they are dug.

2623. A California orange grove.

The prevailing custom in California is to plant the trees in orchard form in squares 22 by 22 feet or 22 by 24 feet, the former requiring ninety trees to the acre. Great care is used to keep the bud-union above the ground and free from the soil. Yucca or paraffined pasteboard trunk-protectors are almost universally used to prevent sunburn. Often the trees are planted out ahead of canal-construction and watered for a year or two from a tank wagon.

Soils and fertilizers.

The character of soil for orange-culture is not so important as its physical arrangement. If the soil is deep, fertile, well drained, and free from layers or strata of a different physical make-up from the main body of the soil, for 5 or 6 feet in depth, it does not matter so much whether the soil is light sand, heavy adobe, loam, or disintegrated desert granite. Excellent orange orchards exist in all these types of soil. It is more pleasant and convenient to cultivate a loam than an adobe, and it is easier to irrigate a loam than a light sand. These things should always be taken into account, but the successful growth of the trees depends more on the uniformity than upon the character of the soil. Upon shallow soils, trees will succeed for a while, but artificial feeding must be resorted to earlier. No soil less than 2 feet deep should be considered safe for oranges. Soils underlaid by hardpan, or layers of open gravel are apt to cause functional derangements of the nutrition of the trees. The ideal soil is a friable easily worked loam, 8 or more feet deep, growing gradually lighter in color and texture as the depth increases. This not only provides a large storehouse of plant-food but a great reservoir to hold water. Of the two most common conditions, it is much better to have a light topsoil over heavy clay subsoil than a heavy clay topsoil over sand or gravel.

It is the custom to plow the orchards once a year, usually in the spring at the time of turning under the green-manure crop. Throughout the spring and summer, the soil is clean cultivated to a depth of 4 to 8 inches. Thorough cultivation and the reëstablishment of the dust mulch follows each irrigation during summer. For this work, either disc, spike-tooth cultivators, or spading harrows drawn by three or four horses are used. Orchard tractors are beginning to take the place of horses in the interior valleys. In some soils, the oft-repeated tramping of the horses causes the formation of a "plow-sole" which interferes with the downward course of the irrigating water. This may be broken up every second or third year by running a subsoil plow through the middles in such a way as to cut as few of the large roots as possible. Some growers have abandoned all tillage and cover the ground 8 or 10 inches deep with mulch. The trees do well under this system but the mulching material is expensive and the danger from fire during the dry season is very great.

California soils are, as a rule, noted for their low content of humus. It is imperative that the humus-content be increased and maintained by generous additions of organic matter. The chief source of humus is the vetch green-manure crop, but where the trees are large and shade the ground, the growth of vetch amounts to little, and other means must be resorted to. Large quantities of stable manure, grain, hay, lima-bean straw, and even alfalfa hay, have been used for this purpose, and of late attention has been called to the possibility of using kelp, which is plentiful along the Pacific coast. How to maintain a high humus-content in the soil is today one of the chief problems before the industry.

Commercial fertilizers are commonly used and in increasing amounts from the time the trees are five or six years old. There is probably more difference of opinion and diversity in practice in connection with the use of commercial fertilizers than with any other phase of the business. The amount of application runs from two to forty pounds to each tree, annually, depending upon its size and age. Some apply the fertilizer all at one time, just before the spring plowing, while some make two or three applications a year. California soils are usually high in potassium, and wherever the humus is high, this element is hardly needed. In many cases in which the soil is deep, rich and high in humus, an annual application of ten to fifteen pounds of ground phosphate rock to a tree, together with the vetch crop and five tons of alfalfa or bean straw to the acre every alternate year will be a satisfactory program. Orange trees are very susceptible to alkali. Where the soil contains .2 of 1 per cent of total salts, the trees begin to decline. A total salt-content of less than .1 of 1 per cent is usually considered safe. These figures will vary somewhat, however, according to the proportion of the different salts, which, taken together, are known as "alkali," some of which (such as sodium carbonate) are very injurious.

Irrigation.

On none of the citrous areas of California is the rainfall sufficient. Irrigation is practised in every orchard. For the most part, water is taken out of streams near the upper headwaters and conveyed by gravity through cement canals sometimes for hundreds of miles to the citrous orchards. Often the descending water generates electrical energy to be used in pumping additional supplies from wells. The water is distributed through steel or concrete pipe-lines and delivered at the upper end of the furrows. Usually the grower buys the water-right with the land and is assessed annually for the upkeep of the system serving him. The keys to the water gates are kept by a water-boss or "zanjero" who measures out to each grower his proper allotment. The amount of water required varies with the character of the soil and the age of the trees. Full-grown bearing trees require from 1 ordinary miner's inch continuous flow to 10 acres up to as much as an inch to 3 acres, depending on the rainfall and whether the soil is a heavy clay or an open sand or gravel. An irrigation is given every month or six weeks during the summer and less often in winter, according to the rains. In heavy soils, the water is run for three or four days at each irrigation in very small streams through four deep furrows to each tree row. The water is cut off when tests with a soil-tube show the soil to be soaked 5 feet deep. In very light porous soils, it is necessary to throw up ridges each way, leaving each tree in the center of a large basin. These basins are filled quickly with a large stream. It is only by the use of large, rapid streams that water may be conveyed across and distributed over such open and porous soils.

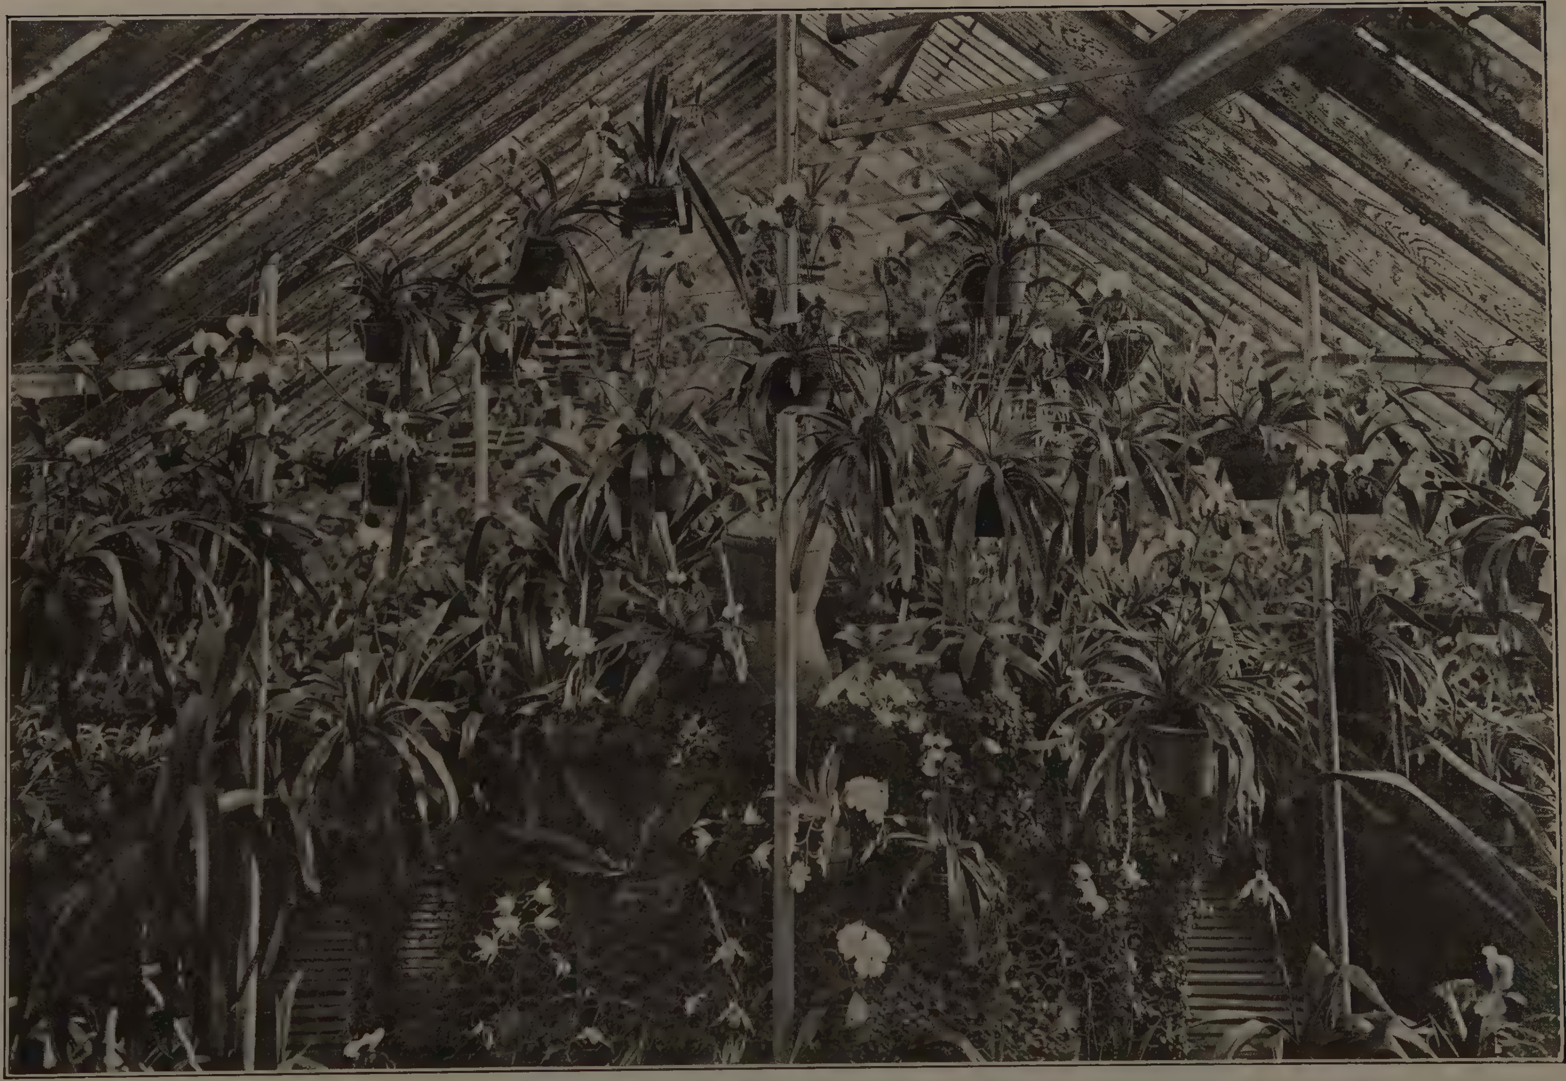
The common or spring vetch (*Vicia sativa*) is very commonly grown as a green-manure crop in southern California. It is planted in September and turned under in February before the trees start the spring growth. The seeds are large and germinate well and the vines suffer less from the trampling incident to harvest than some other green-manure plants. Canada field peas, Tangier peas, bur clover, fenugreek, and sour clover (*Melilotus indica*) are occasionally used in place of the vetch. In northern California, bur clover volunteers satisfactorily and is commonly used. Summer green-manure crops, such as cowpeas, are coming into use wherever there is sufficient cheap water available to supply both the trees and the peas during the dry hot months.

Pruning.

Orange trees are pruned somewhat differently according to the variety. The young Washington Navel tree should not be pruned for the first two or three years after being headed and set in the orchard. Especially if budded from the best type of wood, it may be depended upon to form a good head by itself. Suckers should of course be removed whenever they appear. The Valencia is a more rampant grower, and the young upright shoots are apt to grow too long before branching. They should be pinched back. In pruning old trees, the following rules are thought to embody the best practice: Remove suckers whenever and wherever they appear. Remove the too vigorous vertical shoots which tend to produce coarse fruit. Remove old brush of waning vitality. Thin the tops and, to some extent, the sides so as to allow proper airing and lighting of the interior foliage, thus encouraging the production of high quality, inside fruit. Remove all dead twigs from the fruiting brush. Navel trees rarely need propping, while Valencia trees, unless the limbs are kept short and stout by pinching, are apt to require a great deal of propping.

Harvesting.

California oranges are harvested the year round, the Navels, from November 1 to May 1; seedlings and miscellaneous varieties during May; and the Valencias, from June 1 to November 1, thus overlapping the next Navel crop. A ripe Navel will remain in prime con-



LXXIX. An orchid fancier's house.—Cypripediums, Selenipediums, Miltonias, Lælias, Oncidiums.

dition on the tree for two months, a Valencia for six months or longer.

Oranges are picked with extraordinary care to prevent injury. They are never pulled, but are clipped flush with the "button" with round-pointed clippers. The fruit is collected in canvas bags carried by the picker, which open at the bottom and allow the fruit to slide gently into wooden lug-boxes. The unbroken skin of an orange is very resistant to decay, but the least abrasion, no matter how slight, whether caused by withdrawing the orange carelessly from the branches, or by the finger-nails, or by placing the fruit in boxes in the bottom of which a few grains of sand or dirt have fallen, is almost sure to become inoculated with spores of decay fungi, such as the blue-mold or the soft-rot. Many growers do not take all the fruit from the trees at one picking, but pick the lower fruit first, thus getting it out of the way of frosts which are most severe near the ground; and brown-rot, which is splashed up from the soil by winter rains; and also to relieve the strain on the branches. The standard car is made up of a certain proportion of the different sizes, hence it is customary to go over those remaining on the trees, selecting certain sizes to meet the daily demands at the packing-house. Formerly, picking was paid for by the box, but the tremendous losses from the decay resulting from rapid work has brought about a complete change to day labor.

The lug-boxes of fruit are hauled to the packing-house on spring wagons or auto trucks and weighed in. The fruit is then stored in the same boxes from one to five days, in order that the rind may shrink and the surface cells become less turgid and subject to abrasion. In this condition, oranges will stand a large amount of handling and tumbling about in the padded machines without injury. The fruit is first run through a brusher which removes dust and dirt. In case there is smut from scale insects or soot from oil-pots, they are put through a washing machine containing a $\frac{1}{50}$ of 1 per cent solution of copper sulfate in water. The fruit next travels on belts before the graders who, considering color, shape, smoothness and blemishes, sort the salable fruit into three grades, standard, choice, and fancy. Each one of these grades, after being weighed on automatic scales, passes through a separate sizing machine which delivers each of the eight or ten sizes into a separate, heavily-padded canvas bin. The packers, mostly women, wrap each fruit in printed absorbent tissue paper and place it in the box with great dexterity and skill, averaging sixty boxes a day. A very high pack is customary, and after the covers are forced on and nailed, the boxes are delivered by automatic carriers to the car or the pre-cooling room. One hundred lug-boxes will usually pack out about sixty packed boxes. The cars vary in capacity, depending on whether they are provided with collapsible ice-bunkers. The standard car contains 384 boxes loaded two tiers on end and six rows wide and including not more than 10 per cent of the following sizes, 96, 112, 250, and not over 20 per cent of the 126 size. The remainder of the car may be divided among the 150, 176, 200 and 216 sizes. Cars other than standard are discounted on the market according to the number of the off sizes they contain. The freight is figured on an estimated weight of seventy-two pounds to the box. In summer about five tons of ice are placed in the bunkers after loading and the cars are re-iced in transit as needed, unless they have been pre-cooled, in which case the initial icing suffices. The average time between San Bernardino where the Santa Fe trains are made up, or Colton where the Southern Pacific trains are made up, and New York is about fourteen days. The packing-houses vary in capacity up to twenty carloads a day. In no other fruit industry have the appliances for handling the fruit in the packing-house been so highly developed.

While a few of the larger growers still look after the sales of their own fruit, and a few sell the fruit on the trees to various fruit companies and commission men, the larger part turn their fruit over to a large and very strong coöperative organization of growers known as the California Fruit-Growers' Exchange. This organization began business in 1895 but was reorganized in 1905. In 1915, the Exchange handled about 62 per cent of all the citrous fruits shipped out of the state. The Exchange has greatly increased the consumption of citrous fruits by advertising and better distribution. The business of the Exchange is to "provide for the marketing of all the citrous fruit of members at the lowest possible cost under uniform methods, and in a manner to secure to each grower the certain marketing of his fruit and the full average price to be obtained in the market for the entire season." Much of the fertilizer and other supplies used in the industry are secured through a coöperative store known as the Growers' Supply Company. In 1914 this store did a business of $3,319,062.04 at an operating expense to the members of ¾ of 1 per cent on each dollar of business transacted.

Varieties.

A large list of varieties of oranges has been tested out under California conditions, but the law of "the survival of the fittest" has worked rapidly and today two varieties dominate the field, viz., the Washington Navel and the Valencia Late. While old orchards of other varieties are still producing considerable quantities of fruit, new plantings are now practically limited to these two varieties. The Washington Navel originated at Bahia, Brazil, in the early part of the nineteenth century and was introduced into California by William Saunders, of the Department of Agriculture, in 1870, through Mrs. L. C. Tibbet, of Riverside. This variety now known as the "king of oranges" rapidly gained in popularity until at the present time nearly 80,000 acres of it are planted. It owes it success to the following characteristics: fruit large, smooth, with fine color and flavor, seedless, a splendid shipper, and having a navel mark which serves on the market as a trade-mark. The tree is semi-dwarf, precocious, prolific, and a regular bearer. The Navel is prone to sport and much care should be used in cutting budwood. The Thomson Improved is the best example of a desirable sport from the Navel. The Navel reaches its highest development in the interior valleys.

The Valencia Late originated in the Azores and was introduced into the United States in 1870 by S. B. Parsons, of Long Island, through Thomas Rivers, of England. The Valencia reaches its highest development along the coast. It is a poorer orange than the Navel, but it is the only variety which remains on the trees in good condition until late fall or early winter. Other varieties still marketed to some extent from old groves are Mediterranean Sweet, Paper Rind, Jaffa, Ruby Blood, and Seedlings.

Insects and diseases.

The following insect pests occur in the California citrous orchards: the black scale, red scale, yellow scale, purple scale, cottony cushion scale, soft brown scale, citricola scale, hemispherical scale, greedy scale, oleander scale, citrus mealy-bug, red-spiders, silver mite, thrips, aphis, orange tortrix, Fuller's rose beetle, and a few others. More than $500,000 are expended in southern California each year combating the scale insects. The cottony cushion is controlled by a predaceous beetle, but the other scales are controlled by fumigation with hydrocyanic acid gas under movable tents made especially for the purpose. The cost of fumigating a medium-sized tree averages about 35 cents and the work must usually be repeated every second year. Spraying citrous trees for scale insects is almost obsolete in California. The black and purple scales are most damaging along the coast, while the red and yellow are severe in the interior valleys as well as the coast country. In Tulare County, a species of thrips has done much damage by scarring the fruit and distorting the leaves. The Tortrix worm is the only insect which burrows into the orange.

Gum disease is the most serious fungous disease of the tree in California, while armillaria root-rot, mal-di-gomma, trunk-rot (Schizophyllum), twig-blight (Sclerotinia), wither-tip (Colletotrichum), and damp-off fungi are minor troubles. Physiological diseases of the tree include squamosis or scaly bark, exanthema, chlorosis, mottled-leaf, die-back, and leaf-gumming. Fungous diseases of the fruit are: brown-rot (*Pythiacystis citrophthora*), blue-mold (*Penicillium italicum*), green-mold (*Penicillium digitatum*), gray-mold (*Botrytis vulgaris*), sooty-mold (*Melilola Camelliæ*), cottony-mold (Sclerotinia sp.), gray scurf and navel end-rot (*Alternaria citri*).

Physiological defects of the fruit are: sunburn, frost, off-bloom, exanthema, corrugations, bottle-neck, fingers, yellow-spot, double navel, brown-spot, stem-end spot, cracks, puffs, splits, peteca, red-blotch, and others.

Control measures, more or less satisfactory, have been worked out for the larger number of insects and diseases prevalent in the state.

Protection against frost.

The different kinds of citrous fruits vary in the amount of cold they will endure without injury. The amount of injury done by a given degree of cold upon a given variety will vary, also depending upon the degree of dormancy, the state of the weather just preceding and just after the freeze and the length of time the cold lasts. Many thousand acres of land in California are well suited for growing citrous fruits except for the fact that they are subject to occasional frosts which destroy the crop and sometimes injure the trees. It is natural, therefore, that under such conditions, the citrous growers of California should be pioneers in the work of frost-protection. A great deal of experimenting has been done along the line of diminishing the radiation of heat and by raising the dew-point. It has been demonstrated, however, that the most practicable and satisfactory method of fighting frost is by adding heat directly to the trees through the agency of fires distributed throughout the orchard. Some ten or more types of patent orchard-heaters are now on the market, but the kind the citrous growers find most satisfactory is a round sheet-iron pot of three or five gallons capacity fitted for burning low-grade distillate or crude-oil. The pot should be provided with a suitable cover to keep out the rain and a draught by which the size of the flame may be regulated to suit the degree of cold to be overcome. The less smoke is produced, the better. The smudge commonly used by deciduous fruit-growers is objected to on the ground that the fruit is covered with soot and it is both expensive and damaging to the keeping quality of the fruit to clean it properly. Citrous growers prefer to generate the additional amount of heat necessary to compensate for the lack of smoke.

Many small fires are better than a few large ones. The heaters are usually placed one to each tree or about ninety to the acre throughout the orchard with an extra row along the windward sides. Each ranch should be provided with an oil-reservoir which will hold enough oil to fill all the heaters on the ranch five or six times. When properly equipped with heaters, the temperature of an orchard can be maintained during the night at 10° F. above that of the surrounding country.

The effects of frost on oranges appear as a spotting of the skin and a softening of the outward side of exposed fruits. The juice disappears, leaving the interior dry and pithy. Slightly frosted oranges occasionally develop a very bitter taste. Fruit from the same trees will often grade all the way from sound to badly frosted, depending on the position the fruit occupied on the tree. The method of separating sound from frozen fruit is based on specific gravity.

The machine consists of an oblong tank through which water may be made to circulate at definite speeds by a small propeller. The oranges roll down an incline and drop into the moving water from a height of a foot or more. The light frosted oranges bob up to the surface quickly, while the sound, heavy fruit is slower to rise. Meanwhile the oranges have been carried along by the current, the sound fruit passing under, and being caught by a horizontal wire screen, while the light fruit is carried along above it. At the farther end of the tank the two grades are lifted by conveyors and delivered to separate bins. By adjusting the position of the screen and the rate of flow of the water, any degree of separation desired may be secured.

By-products.

The manufacture of citrous oils, perfumes, citrate of lime, and other by-products has never been developed commercially in California, although at present much experimenting is being done in an effort to encourage such an industry, which is badly needed. At present, the culls mostly go to waste or are applied to the land as fertilizer. The manufacture of marmalade and citrate of lime has been attempted but has not as yet assumed importance.

ORCHARD. In North America, the word orchard is applied to a plantation of fruit-trees. The orchard is one part of the typical American farmstead, comprising either a few trees for domestic supply in a regularly laid-out plantation or a larger area planted as a source of revenue. Commercial plantings of large extent are also made without particular reference to a homestead. Except in the warmer parts, the apple tree comprises the usual orchard planting. Plantations of bush-fruits are not known as orchards in this country. By custom, orchards of citrous fruits are usually called groves.

ORCHARD PROTECTION: See article on *Frost.*

ORCHIDS. A vast assemblage of herbaceous plants, mostly with unusual and interesting flowers, of which about 15,000 species are at present known. This number is being augmented yearly as the regions which they inhabit become more accessible to collectors. A single collection in New Guinea in 1907 to 1909 brought to light 1,102 new species,—an indication of the number of new forms still to be expected from little-explored regions. Since the first edition of the "Cyclopedia of American Horticulture" was published, the number of known species has been increased by about 5,000. Probably the species now outnumber those of the great family Compositæ.

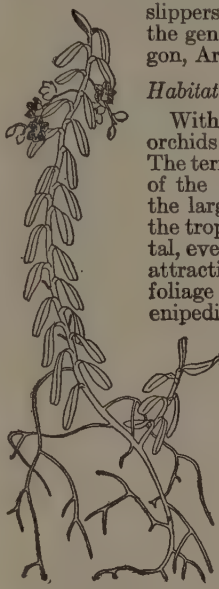
Although widely distributed, the orchids are seldom abundant in any place as to individual plants. They are mostly inhabitants of special or particular places. Orchids are also highly specialized in structure, particularly in character of flowers, in this differing widely from the broadly generalized structure of the Compositæ.

These very special plants, with marvelous range of form and color, have naturally excited the greatest interest on the part of cultivators, and great collections have grown up. To a large extent, these collections have been renewed from fresh importations from the wild, but the recent discoveries of symbiotic relations in germination, as well as better understanding of cultural requirements, will constantly increase the domestic supply. In the culture of a wide range of orchids the gardener exhibits his mastery of the arts of cultivation. The recent studies in this field afford very definite practical applications of scientific methods.

Distribution.

The orchids are distributed over all parts of the world with the exception of the polar regions and the great deserts. About 85 per cent of the species occur in the tropical and subtropical regions. Here they are found to a great extent in the mountainous districts. In some parts of the Himalayan region, the orchids constitute the most abundantly represented family of plants in point of number of species. Most of the tropical species are endemic. The widely distributed species are found in the North Temperate and the Subarctic zones. They include such forms as *Calypso bulbosa* (formerly known as *C. borealis*), *Microstylis monophyllos*, *Liparis Lœselii*, and species of Orchis (or Galeorchis). These are found throughout the northern regions of both hemispheres. The greater number of the orchids are distributed in three regions of the earth: (1) The tropical African region, including the islands to the east, furnishes comparatively few species to cultivation. These mostly belong to the genera Angræcum, Bulbophyllum, and Disa. This region also contains a number of endemic genera not of great interest to cultivators, and representatives of such widely distributed genera as Habenaria, Liparis, Microstylis, Epipactis, and others. (2) Unusually rich in genera is the region of tropical Asia, including the neighboring groups of islands. Typical of this region are the large genera Dendrobium, Eria, and Bulbophyllum, and many smaller genera, including Paphiopedilum, Cœlogyne, Cymbidium, Sarcanthus, Saccolabium, and Vanda. Among the genera common to this region and the African region are Bulbophyllum, Phaius, Calanthe, Liparis, and Microstylis. (3) The tropical American region, embracing Mexico, Central America, tropical South America, and the neighboring islands, occupies an isolated position and consequently contains an unusually large number of endemic genera, many of which are represented by hundreds of species. Besides the large endemic genera Epidendrum, Pleurothallis, Oncidium, and Odontoglossum, this region contains many of the commonly cultivated genera, among which may be mentioned Cattleya, Lælia, Masdevallia, Schomburgkia, Brassavola, Lycaste, Peristeria, Stanhopea, Gongora, Zygopetalum, Miltonia, Phragmipedilum, and many others. Some genera, among them Vanilla, Bulbophyllum, Calanthe, Liparis, and Microstylis, are common to both this region and the Old World. Compared with these great floristic regions, the temperate lands of the southern hemisphere are of less importance. Of the south African genera, Disa and Calanthe furnish a few species valuable to cultivation. Australia contains many genera in common with the tropical Asiatic region, but few of the cultivated species are derived from there. In temperate South America the orchids are sparsely represented by a few species of Epidendrum, Oncidium, Spiranthes, Habenaria, and a few other genera. From a horticultural standpoint, the species of this region are of little importance. About twenty genera are found in the northeastern United States and Canada, mostly in swamps and moist grounds; among them are the Cypripediums or lady's slippers, and many beautiful plants in the genera Habenaria, Pogonia, Calopogon, Arethusa, and Calypso.

2624. Monopodial growth in a vanda.



2625. Monopodial growth in Renanthera Cathcartii.

Habitat.

With regard to their habitat, the orchids are either terrestrial or epiphytic. The terrestrial orchids include the species of the temperate regions and many of the largest and most stately orchids of the tropics. Many of these are ornamental, even when not in flower. A few are attractive on account of their variegated foliage and some, like Sobralia and Selenipedilum, are admired on account of their tall graceful stems.

Most of the terrestrial orchids are green plants which obtain their carbon supply from the carbon dioxide of the air, but a few forms either lack chlorophyl entirely or possess it only in traces too small for normal photosynthesis. These forms are saprophytic in their mode of life and depend for their carbon food upon the organic matter of the humus. The appellation of parasites, which is sometimes given to these forms, is erroneous. True parasites are not known among the orchids.

In the saprophytic orchids, the subterranean part is either a much-knotted coral-like rhizome devoid of true roots (Corallorhiza, Epipogon), or a subterranean rootstock producing numerous crowded fleshy roots (Neottia, Galeola). The annual shoots are yellowish, brownish, or reddish, without true leaves, but bearing scales and a terminal inflorescence which may be reduced to a solitary flower. Very curious are the members of the Javan genus Galeola, whose leafless climbing stems attain a height of 100 feet, ascending trees by means of roots that arise opposite the scale-leaves, and producing a terminal and many lateral racemes in the upper part of the stem. The saprophytic orchids are not cultivated except occasionally in botanic gardens, as the conditions necessary for their existence are not readily imitated.

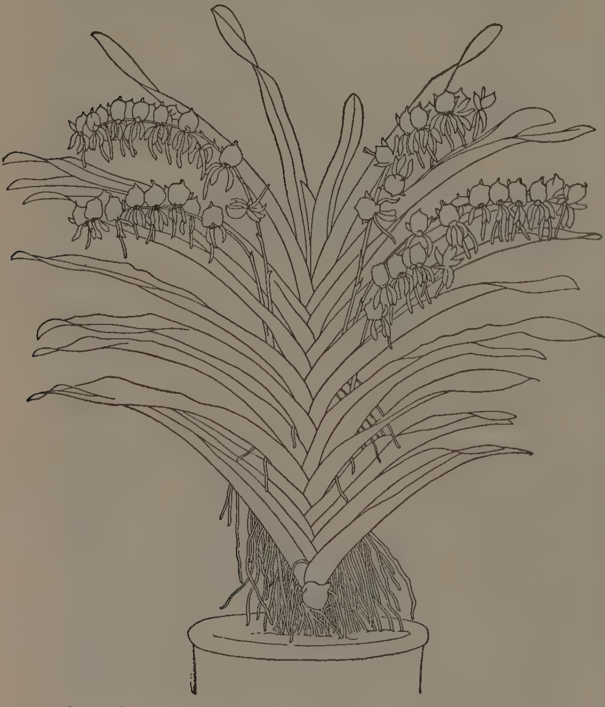
The epiphytic orchids exhibit the most varied forms. They are confined to the tropics and subtropics, where they inhabit branches of trees, dead trunks, and often barren rocks in exposed places. They grow mostly in regions where a part of the year is unfavorable to vegetation. As an adaptation to these conditions, they have developed special food reservoirs (pseudobulbs) terminating each season's growth. In this group there are comparatively few plants of attractive habit. They are usually devoid of graceful foliage, each pseudobulb bearing a few stiff leathery leaves. The older pseudobulbs become shriveled and leafless, detracting from the appearance of the plants, and in Pleione the plants are entirely leafless at the flowering time. In some of these, however, the pseudobulbs are numerous and closely crowded, and retain their foliage, making plants of neat compact habit (Cœlogyne, Miltonia). In their mode of life, the epiphytic orchids resemble the green terrestrial orchids. For their mineral nutrients they are dependent upon the material which is mostly the residue of decayed organic matter which accumulates among their roots. They are not saprophytic or parasitic.

Morphology of the vegetative parts.

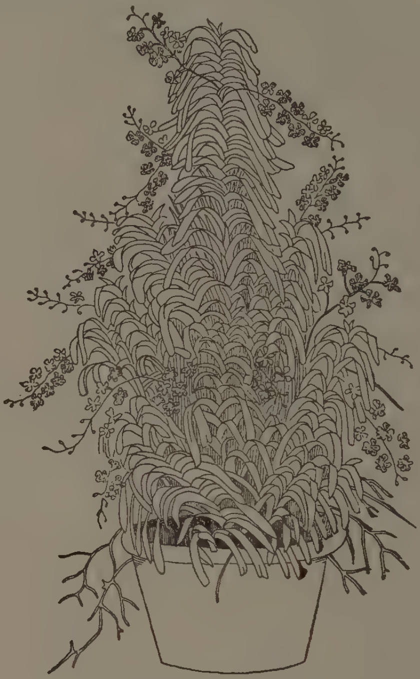
All orchids are perennial herbs which, according to their mode of growth, fall into two groups—the monopodial and the sympodial.

In the monopodial orchids, the growth of the main stem is continued indefinitely by the terminal bud. (Figs. 2624–2627.) Lateral branches are frequently produced, but they do not regularly assume the part of the main axis and do not under ordinary conditions exceed it in length. The growth of the main stem and its branches may be interrupted for a time by a period of rest, but such interruption is not manifested on the stem by the formation of scales and juvenile leaves when growth is resumed. All leaves are similar. The habit of the monopodial orchids is various. In spite of their indeterminate growth, they do not usually attain great size. This fact is explained by the slow growth of the plants, which often require several months to develop a single leaf. Nevertheless, some of the species attain stately proportions. The climbing species of Renanthera sometimes reach a length of 12 feet or more in greenhouses. Some of the vandas, aërides, and angræcums form handsome plants 1 to 2 feet high and well clothed with long distichous leaves. (Figs. 2626, 2627.) While these forms grow into tall leafy plants, others, like Phalænopsis, remain almost stemless and possess only a few large fleshy leaves. The extreme reduction is represented by such forms as *Polyrrhiza funalis*, in which the stem is reduced to a mere scaly bud seated on a mass of tangled green roots which perform the function of photosynthesis.

In the sympodial orchids, the growth of each shoot is definitely terminated usually after one, rarely after two or more seasons. The development of the plant is continued by buds originating in the axils of the scale-leaves at the base of the parent shoot. (Figs. 2628, 2629.) The lower part of each new axis is prostrate at first and often subterranean and bears only scales. It is known as the rhizome. In many terrestrial orchids of the temperate regions, the lower terminal part of the rhizome forms a tuberous root from whose apex the shoot of the next season arises. (Fig. 2630.) In a few sympodial orchids with perennial stems and climbing habits, branches originate in the axils of the stem-leaves (Vanilla). These bear a strong resemblance to the monopodial orchids, but all the branches as well as the main stem are finally terminated by inflorescences.



2626. Angræcum superbum, to show a monopodial growth.



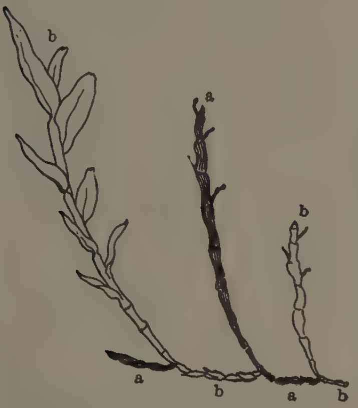
2627. Vanda tricolor, a branching monopodial orchid.

The general habit and appearance of orchid plants depends to a great extent on the nature of the rhizome. When this is long, the plants have a loose straggling habit (Epidendrum). When it is short, the plants are compact (Masdevallia, Cattleya, Cœlogyne). The rhizome may be much branched and give rise to numerous upright shoots (Sobralia, Cœlogyne, Disa), or it may be simple and give rise to only one shoot annually as in many of our native orchids. In some species, the rhizome assumes suberect or climbing habits (Lycaste).

The upright part of the axis presents a great diversity of forms which may be grouped in two classes according to the position of the inflorescence. This may be either terminal or lateral.

In the forms with a terminal inflorescence, the leafy part of the stem may be very short so that the leaves appear as a rosette on the ground while the upper part of the stem bears bracts from whose axils the flowers appear (Goodyera, *Orchis rotundifolia*, *Cypripedium acaule*), but generally it is more developed and bears a succession of leaves which are gradually reduced to bracts in the upper part (Habenaria, Cypripedium, Disa, Thunia). In Selenipedilum and Sobralia, the tall reed-like stems reach a height of 6 to 15 feet and often form dense thickets. In Vanilla the stems are long, branched, and climbing. In many of the epiphytic forms the stem is thickened into a pseudobulb. This may consist of a single internode which bears one or two leaves at its summit (Cœlogyne), but more frequently several internodes are enlarged to form the pseudobulb, which is then clothed with leaves at least when young, and later bears the scars of fallen leaves (Lælia, Cattleya, Epidendrum). Figs. 2631 and 2632 show the two forms of pseudobulb. Sometimes the whole stem is more or less fleshy without being enlarged into a distinct pseudobulb (Epidendrum spp.).

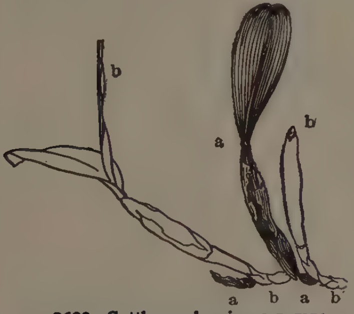
An equally varied display is presented by the sympodial orchids having a lateral inflorescence. Nearly stemless forms, or forms in which the stem is developed as a subterranean structure often of curious configuration, occur in the Phaiinæ (Phaius, Calanthe, Bletia), the Cyrtopodiinæ (Lissochilus, Warrea), and the Corallorhizinæ (Corallorhiza, Aplectrum). In others, the stem is developed as a pseudobulb consisting of several internodes clothed with leaves (Cymbidium, Mormodes, Catasetum, Chysis), or it is elongated and cane-like as in Dendrobium, which, however, may belong to the terminal-flowered forms since some of the near relatives of this genus produce terminal flowers. In species of Grammatophyllum and Cyrtopodium, the tall leafy pseudobulbous stems attain magnificent proportions, reaching a height of 3 to 15 feet. (Fig. 2633.) In the greater number of the lateral-flowered forms, only a single internode of the stem is enlarged to form a pseudobulb. (Fig. 2634.) Such is the case in Odontoglossum, Oncidium, Bulbophyllum, Trichopilia, Zygopetalum, Lycaste, Stanhopea.



2628. Dendrobium, diagrammatic sketch showing growth of sympodial orchid. The dark and light parts, *a a* and *b b*, represent each the growth of one shoot.

The inflorescence of the orchids is throughout of the indeterminate type, that is, truly terminal flowers are not produced. Even in those cases in which the flower is solitary, the presence of a few bracts above it show its axillary position. In the monopodial orchids, the inflorescence is of necessity always axillary since the growth of the vegetative shoot is indeterminate, but in the sympodial orchids it may be either axillary or terminal, as described above. In *Cœlogyne cristata*, and a few others, the inflorescence is terminal on special branches of the sympodium.

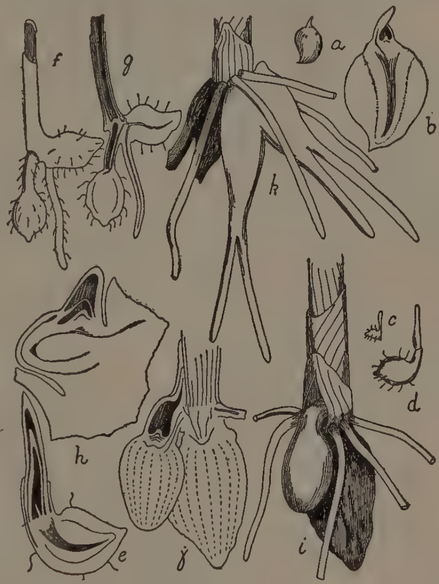
The form of the inflorescence is various. Solitary flowers occur in many genera, as Cypripedium, Lycaste, Anguloa, and others, but more commonly the inflorescence is racemose or paniculate. The raceme may be close and compact as in some of the monopodial orchids (Aĕrides, Saccolabium), or loose with few to many flowers, as in most of our native orchids as well as in most of the commonly cultivated species. In Renanthera, the gigantic racemes attain a length of many feet. Large paniculate inflorescences are characteristic of some species of Oncidium and related genera. The inflorescences are sometimes of a climbing habit and attain a height of several yards. The large perennial panicles of some species of Phalænopsis bear as many as 200 flowers. In Vanilla, large racemes arise from the axils of the upper leaves so that the whole upper part of the plant may be considered as a huge panicle.



2629. Cattleya, showing a sympodial growth. The light and shaded parts, *a a* and *b b*, each represent one year's growth.

Morphology of the floral parts.

No group of plants exhibits so great variety of modifications of the floral structures as the orchid family. Some of the forms are shown in Figs. 2635, 2636, 2637. Fundamentally the flower is of the liliaceous type; but, by the supression of some parts and the modification of others, the structure of the flower has been so changed that in its outward appearance it bears little resemblance to the typical monocotyledonous flower. In flowers of the liliaceous type, there are normally present two outer whorls of floral organs, the sepals and the petals, two whorls of stamens, and an inner whorl representing three carpels. In the orchid flower, the two outer whorls, the sepals, and petals are developed. Of the stamens, only two are fertile in the Diandræ (Cypripedium and related genera), while in all the other orchids (Monandræ) only a single stamen is fertile. The three carpels are always present. The three corresponding stigmas are developed in the Diandræ, while in most of the remaining orchids only two stigmas are receptive (Monandræ). (See Fig. 2638.)



2630. The tuber formation of terrestrial sympodial orchids, *a, b, c, d*, young seedling stages of Orchis militaris; *e*, section through the same; *f* and *g*, plants the following spring with the tubers completed; *h*, section showing beginning of lateral shoot; *i*, tubers of mature plant; *j*, longitudinal section of same; *k*, tubers of Orchis latifolia.

The relation of the parts of the flower to one another is greatly changed by the growth of the floral axis. This is convex in the very young stages of development but it soon becomes cuplike by the cessation of growth of the center and the more rapid growth of the peripheral zone. A hollow or tubular axis is thus produced, within which are formed three longitudinal ridges or placentæ upon which the ovules are borne. The hollow floral axis constitutes the "inferior ovary" of the orchids (Fig. 2639) and at the same time acts as the stalk or pedicel of the individual flowers of the inflorescence. The ovary is structurally 3-celled. (Fig. 2640.) Besides the carpellary cavity, the axis of many orchids contains another cavity which lies toward the labellum or lip and opens at the base of it. This is a nectary. It may be considered in the nature of the cavity of an adnate spur of the labellum. In the embryonic state, the orchid flower is so oriented that the labellum is situated on the side of the flower toward the axis of the inflorescence, as shown in Fig. 2638; that is, it points toward the apex of the inflorescence. In a few forms this condition is permanent, but in the greater number of orchids the ovary or axis is variously bent or twisted so that in the mature flower the labellum is on the side of the flower away from the floral axis or, generally speaking, on the lower side of the flower.

2631. **Cattleya dolosa, a sympodial orchid with terminal inflorescence and pseudobulbs consisting of several internodes.**

Of all the floral organs the sepals are the least modified. These comprise the outside whorl in Fig. 2638. The one originally opposite the axis of the inflorescence, but which by reason of the turning of the flower just described usually occupies a position adjacent to the axis or on the upper side of the flower, is known as the odd sepal. By reason of its actual position with reference to the flower, it is sometimes called the upper sepal. The other two, which were originally adjacent to the axis of the inflorescence, are the paired or lateral sepals. In most orchids, the lateral sepals are asymmetrical, but noteworthy modifications occur only in a few genera. Sometimes the lateral sepals are partly or entirely united (Cypripedium, Oncidium). In Masdevallia, all the sepals are united into a short tube at the base, and expand above into three blades terminating in long tails. Occasionally, the odd sepal is spurred or saccate (Disa) and very commonly differences in size exist between it and the lateral sepals.

2632. **Cœlogyne Cumingii, a sympodial orchid with terminal inflorescence and pseudobulbs of one internode.**

Of the members of the second whorl, the two lateral ones are usually petal-like while the one opposite the odd sepal is specially modified, and is known as the labellum (*l*, in Fig. 2638). In most genera the lateral petals resemble the odd sepal, although minor differences in form, size, and color are of frequent occurrence. This resemblance is most striking when these parts have some unusual form, as in *Oncidium Papilio*, in which they resemble the antennæ of an insect, or in *Phragmopedilum caudatum*, in which they are longcaudate, attaining a length of 3 feet. In some genera, the lateral petals show no resemblance to the odd sepal (Huttonæa, Masdevallia, Achrochæne). Asymmetry of the lateral petals occurs very frequently.

The odd petal, or the labellum, presents the greatest diversity of form of all the floral organs. Sometimes it is small and inconspicuous (Disa), or it is like the lateral petals (Goodyera). As a rule, however, it is much larger than the lateral petals (as in Fig. 2637), and often it is the most conspicuous part of the flower (Oncidium, Cypripedium, *Odontoglossum Londesboroughianum*). In a few genera the labellum is bifid (Vanda, Listera), but in the greater number of orchids it is evidently three-lobed. One of the most common forms which the labellum assumes is that of a trumpet-shaped tube whose sides are formed by the lateral lobes, while the middle lobe is expanded into a variously shaped blade which is often of a deeper shade than the rest of the flower and ornamented by crests and ridges and color-markings of various kinds which are thought to be of service to the flower by attracting insects and guiding them to the nectar and hence to the pollen and stigmas. This form of labellum is characteristic of many of the most beautiful orchids in cultivation (Cattleya, Lælia, Dendrobium, Phaius). Frequently the labellum is more or less concave, and in Cypripedium and related genera it has the form of a sac (Fig. 2636) often compared to a shoe as the name "lady's slipper" indicates. In many species, the labellum is strangely transformed and more or less distinctly segmented into a basal part, the "hypochil," and a terminal petaloid portion which is then designated as the "epichil." Sometimes the differentiation is carried still further and an obscurely defined section, the "mesochil," is recognized between these two. The hypochil is the stalklike, or somewhat concave winged part which joins the column. It is not clearly distinguishable from the foot of the column described below. The mesochil is usually provided with two lateral cirrhous appendages termed "pleuridia," and a central callus known as the "mesidium" (Phalænopsis, Stanhopea, Peristeria, Gongora). (Fig. 2641.) The epichil is the simple or lobed terminal part of the labellum. In color and consistency it usu-

2633. **Grammatophyllum speciosum, a sympodial orchid with lateral inflorescence and pseudobulbous stems consisting of several to many internodes and attaining a height of several feet.**

ally resembles the lateral petals. Often it is movably attached to the mesochil. In some forms of the Pterostylidinæ the labellum is sensitive, and when irritated by an alighting insect closes sharply against the column, entrapping the animal.

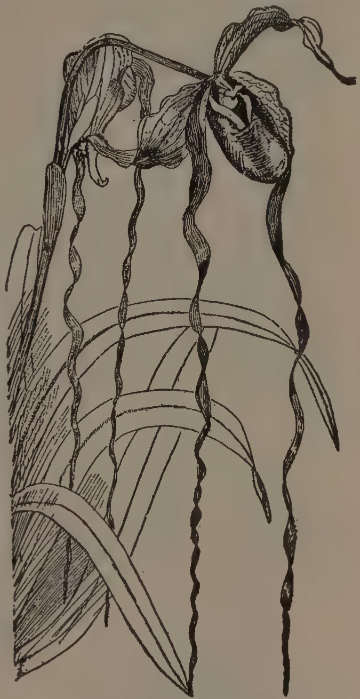
2634. Odontoglossum Œrstedii, a sympodial orchid with lateral inflorescence, and pseudobulbs consisting of a single internode.

2635. An orchid flower (with unexpanded bud above), to show the very long spur. — Macroplectum sesquipedale. (× about ¼)

The morphological center of the flower is occupied by a fleshy elongation of the floral axis known as the column. This is short and inconspicuous in some forms, but in most species it is well developed. It is usually bilaterally symmetrical. The posterior surface is convex while the anterior surface, toward the labellum, is concave. Usually the column is curved toward this face. In a few forms, like Cycnoches, the curvature is very marked, while in Coryanthes the column is asymmetrically bent. Within the column is a canal continuous with the carpellary cavity. (Fig. 2642.) The column is primarily of importance because at its upper end it bears the stamens and the stigmas and auxiliary structures which function in the pollination of the flowers. Besides these organs, it sometimes bears a number of outgrowths and appendages which give it a very complex appearance. Often the labellum does not appear to be attached directly to the column, but is borne upon a special fleshy outgrowth at its base known as the "foot" of the column. Between the forms in which the foot of the column is not developed and those in which it is present, no distinct line can be drawn. In our native orchids it is mostly absent. In Grammatophyllum there is a small cuplike depression upon whose anterior wall the blade of the labellum is attached with a narrow base. It is here a matter of interpretation whether the anterior wall of the cup is regarded as a part of the labellum or as the foot of the column. (Fig. 2643.) In other cases where the foot is more distinctly developed, the labellum is often plainly attached to its lower side, as in Paphinia, Pescatoria, Phaius, Bulbophyllum. (Fig. 2644.) Frequently the lateral sepals are decurrent upon the foot or entirely attached to it (*Bulbophyllum Achrochæne*, Fig. 2645). In some forms the lateral sepals and the labellum are borne near the end of the foot while the lateral petals are decurrent upon it (Batemannia). Sometimes the lateral sepals and the labellum are carried entirely away from the other parts by the elongation of the foot of the column, thus giving the flowers strange and fantastic forms (Drymoda, Gongora, Aërides). When the lateral sepals or the petals are decurrent upon the foot they, together with the labellum attached at the apex, often form a "chin" or "mentum" which is present in many orchids, such as Dendrobium, Pescatoria, Lycaste, Batemannia. (Fig. 2646.) Frequently the base of the mentum is extended below into a sac or spur of various forms and length. More often the spur arises from the labellum itself (Phaius, Platanthera). Within the cavity of these spurs or sacs, honey is secreted, and often the walls themselves contain juices which are sought by insects.

The upper part of the column bears the stigmas and the stamens. In the Diandræ, the three pistils are fertile, as indicated by the more or less evidently three-lobed stigma (Figs. 2647 and 2648), but in the Monandræ only two stigmas are receptive. The place of the third is occupied by the curious "rostellum," which separates the anther-bed from the stigmas and prevents the pollen from falling directly upon them (Fig. 2642). The stigmas are usually flat surfaces sunk in a depression in the column below the rostellum. In a few genera they are elevated on stalks (Habenaria), and in Sophronitis they extend partly along two wing-like projections of the column. The essential organs, in other forms, are shown in Figs. 2647–2652.

The stamens in the Diandræ are situated laterally on the column under a shield-like staminodium which is developed in place of the odd stamen of the outer whorl. In the Monandræ, the stamen is situated at the dorsal margin of the column. Its position is sometimes erect, but more frequently it is bent downward with the anther either pendent (Cœlogyne, Fig. 2650), or lying in a depression, the "clinandrum" or "anther-bed," in the top of the column. From the dorsal part of the column a petaloid appendage often arises and extends above the anther. The sides of the anther-bed are formed by outgrowths of the column. They are often developed as crests, ears, or winglike structures ornamenting the column and enfolding the anther. The floor of the anther-bed is formed by the rostellum.



2636. The appendaged flower of Phragmopedilum caudatum.

The anther sometimes remains two-celled, but more frequently the cells are further divided, by longitudinal partitions or cross-walls, into four or eight cells. In a few cases, six cells are formed, probably by the abortion of some of the cells.

The pollen is powdery in some cases, but usually the grains are united by means of a viscid substance into waxy masses termed "pollinia." The number of pollinia corresponds to the number of anther-cells. In many genera, the viscid substance uniting the pollen-grains is prolonged beyond the pollen-mass and hardens into a stalk or "caudicle" within the anther-cell (Fig. 2651). One or two pollen-masses are attached to each caudicle. When the anther dehisces, the caudicles come into contact with masses of sticky matter formed by the disorganization of cells on the upper surface of the rostellum. In many orchids, this substance itself forms the adhesive disk by means of which the pollinia become attached to insects. In others a strip of tissue is separated from the rostellum by the disorganization of the underlying cells, and forms a stalk which in this case is known as the "stipe." When a stipe is formed by the rostellum, the caudicle of the pollen-masses is not produced. In that case, the pollinia become directly attached to the stipe when the anther dehisces. The other end of the stipe forms the adhesive disk. (Fig. 2652.) Whatever its origin, the stalk with its adhesive disk is one of the most important parts of the mechanism by which the transport of the pollen-masses from flower to flower is brought about and by means of which cross-pollination is insured. The details of the process by which this is accomplished have been beautifully explained by Darwin in his classical work, "The Various Contrivances by Which Orchids are Fertilized by Insects."

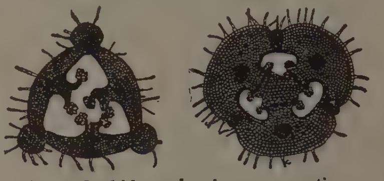
2639. Orchid flower, showing the long stem-like ovary between the two bracts and the other floral parts above.

Dimorphic and trimorphic flowers occur in a few orchids. In the inflorescences of a small group of Oncidiums (Heterantha), only few normal flowers are produced together with many smaller sterile ones which lack the column. In *Renanthera Lowii* the upper flowers of the long inflorescence differ in form and color from the others. The most unusual condition exists in Catasetum, in which there are three very different types of flowers. In some years the same plant produces only one type and in other years all types on a single inflorescence.

The flowers of orchids are commonly noted for their longevity. When not pollinated, the flowers of most genera remain fresh for thirty to forty days, and in some genera even for much longer periods. Only a small number of genera have flowers that wither in a few days (Sobralia, Cirrhopetalum). The persistence of the flowers greatly increases the chances for pollination, which, since it is dependent on particular agencies, is more or less uncertain. After pollination has been effected, the flowers soon wither.



2640. Orchid ovaries in cross-section.—Paphiopedilum Charlesworthii at left; P. Schlimii at right.

The fruit of orchids is usually a dry capsule, requiring a long time to ripen, so that if an orchid flower is fertilized in one rainy season its seeds are not disseminated until the next wet period. Very few have fleshy fruits which dehisce imperfectly or not at all. In them the seeds are liberated only by the decay of the pericarp (Vanilla). The seeds of orchids are minute and extremely numerous, the number in a single capsule having been estimated for different species from several thousands to over a million. The seeds consist of a dry loose large-celled testa inclosing a rudimentary embryo, which in most genera is entirely undifferentiated. (Fig. 2653.)

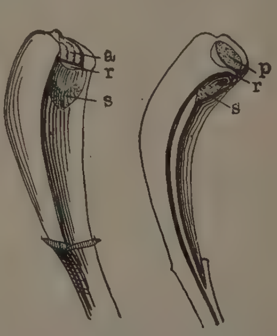
Symbiosis.

So far as known, the roots of all orchids, with the exception of occasional individuals, are inhabited by fungi which live within the tissues either symbiotically or at least without causing any apparent injury to the plant. The fungus hyphæ are primarily found in the cortical tissues, but usually two or three of the outer layers of cells of the cortex are not infected. In the epidermis the fungus is found only in the cells bearing root-hairs, through which long hyphæ pass out into the substratum. The central cylinder and the growing apex of the root are not infected. The extent to which the fungus passes upward in the plant varies with different species and with the condition of the roots. In Neottia, Goodyera, and Corallorhiza the lower part of the stem is invaded sometimes up to the first node. In Epipactis, Cypripedium, and Listera, the roots and rhizomes contain much woody tissue. In such forms, many of the roots are free from fungi, and in the remaining roots, as well as in the rhizomes, the distribution of the fungus is irregular. The basal parts of the roots, which are more or



2642. Column of a cattleya, with a longitudinal section at the right.—*a*, anther; *r*, rostellum; *s*, stigma; *p*, pollinium.

less woody, are not infected; and occasionally individual plants are found which appear to be free from the fungus. In the roots of epiphytic orchids, also, the distribution of the fungi is irregular, only scattered islands of cortical tissue being as a rule infected. Only the parts of the roots which are in contact with the substratum contain fungi. In forms like Vanda and Vanilla, with superficial roots, only the side of the root adjacent to the substratum is infected, while the other chlorophyl-bearing side is free.

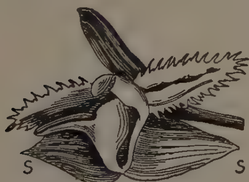
2643. Flower of Grammatophyllum speciosum, showing at the base of a column a cuplike depression to the anterior wall of which is attached the labellum, with a narrow claw.

Within the cells, the fungus has the form of closely coiled and interwoven masses of hyphæ, except in the root-hairs and in the velamen,—the spongy outside covering of the roots of epiphytic orchids,—where long hyphæ occur. The endophytic mycelium is, as a rule, connected with external mycelium in the substratum by means of hyphæ passing through the root-hairs, or, where these are absent, as in *Neottia Nidus-avis*, through the epidermal cells of the rhizome and the roots. In some forms, like Neottia and the epiphytic orchids, such communications have been only sparingly observed, while Corallorhiza and most of the terrestrial orchids have abundant connections with the mycelium in the substratum.

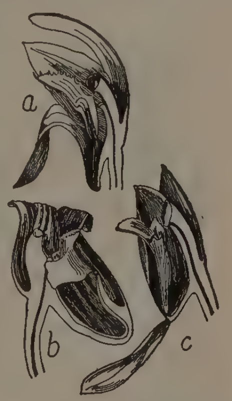
The plants are sometimes permanently infected through the seedling in the way described farther on. Infection also takes place through the root-hairs. When the rhizome and the upper part of the roots are free from fungi, infection must of necessity take place in this way. In epiphytic orchids, and probably in terrestrial orchids also, repeated infections thus occur. In some terrestrial orchids, in which the fungus invades the rhizome, the hyphæ grow out directly from this into the new roots, and also into the bud for the following year. In such forms only a single infection is necessary to establish a permanent symbiosis.

2644. Paphinia cristata, showing at *f* the foot of the column with labellum attached on lower side.

It is generally held that the mycorrhiza fungi supply their hosts with nutrients. That the non-green forms like corallorhiza are supplied with organic carbon compounds in this way can scarcely be doubted, for these plants, lacking chlorophyl, cannot elaborate their own carbohydrates from the carbon dioxide of the air. It is certain, also, as will be described later, that the germination of orchid seeds and the early stages of development of the seedling do not take place without the intervention of the mycorrhiza fungi, but the function of the fungi in these processes remains still to be investigated. To what extent the mycorrhiza fungi function in supplying the plants with water, salts, and organic nitrogenous compounds, is not known. For the greater number of orchids that are equipped with chlorophyl and which can, therefore, utilize the carbon dioxide of the air for the production of carbohydrates, it is not likely that the root-fungi are necessary for supplying them with carbon compounds. There is some evidence, however, that the fungi have a part in supplying the plants with nitrogenous compounds and possibly with phosphorus and potassium also. The fact that the hyphal coils are finally digested in the cells and that the substances which they contain thus become available to the plant, throws no light on this problem for the substances in the hyphæ may have been derived from the plant itself. Investigations up to the present time have shown that orchids do not assimilate free nitrogen from air by the aid of their endophytic symbionts, nor do the fungi themselves in pure cultures fix free atmospheric nitrogen.



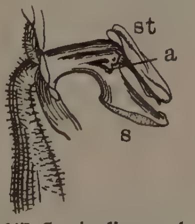
2645. Bulbophyllum Achrochæne, showing (*s, s*) lateral sepals decurrent on foot of column.



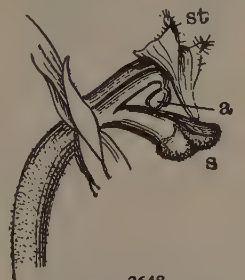
2646. The mentum.—*a*, spur-like mentum of Lycaste Cobbiana; *b*, sack-like mentum of Acanthophippium javanicum; *c*, chin-like mentum of Batemannia Colleyi.

Seedlings.

The growing of orchid seedlings has always been surrounded with much mystery and secrecy. In the large orchid establishments, the secret methods which the expert growers were supposed to possess were carefully protected by locked doors and painted glass, and visitors were seldom admitted to the houses. Yet it was evident that in spite of the carefully guarded practices, chance seemed to play an important part in the culture of orchid seedlings. Rarely were the expert growers uniformly successful. Of the vast number of genera imported, only cattleyas, odontoglossums, cypripediums and a few others could be grown with even a fair assurance of regular success. Some growers were unusually successful with one group and some with another, but generally all were not equally successful with all kinds. The key to this situation was furnished by Noel Bernard who, in 1903, attempted to grow seedlings of a hybrid between *Cattleya Mossiæ* and *Lælia purpurata* under aseptic conditions and found that the embryos swelled and formed green spherules, but that they failed to develop further even after weeks, and finally died. If, however, the seeds were sown on pure cultures of the endophytic fungus isolated from the roots of these plants, the embryo developed normally, forming a spheriod body which soon produced a cotyledon and papillæ with long root-hairs. Further investigations, chiefly by Bernard and by Burgeff, showed that the germination of orchid seeds does not occur except in the presence of the root fungi. Even seedlings of such little mycotrophic forms as Cypripedium and Epipactis, will not develop unless infected, although the mature plants of these species are often found without fungi and do not require their presence

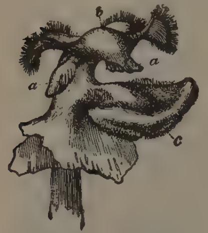


2647. Cypripedium.—*st*, staminodium; *a*, anther; *s*, stigma.



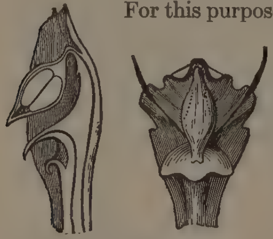
2648. Phragmopedilum caudatum. —*st*, staminodium; *a*, anther; *s*, three-lobed stigma.

The infection of the orchid embryo takes place through the suspensor by means of which the embryo was attached to the nutrient tissue of the ovule (Fig. 2654). From the suspensor the fungus invades the cells in the lower region of the embryo, except the epidermis. The cells become filled with dense interwoven gnarles of hyphæ like those in the roots. The coils in the inner cells undergo a process of digestion, but those in the outer cells remain intact and send hyphæ through the root-hairs of the papillæ into the soil. New papillæ with long absorbing hairs are soon developed and the cotyledon and leaves begin to be differentiated. After three to four months, roots are produced and the young embryo begins to assume the characteristic form of an orchid seedling (Fig. 2655).



2649. Structure of the column of Paphiopedilum Dormanianum.—*a*, *a*, anthers; *b*, body representing the third stamen; *c*, stigma. Underneath are the remains of the floral envelopes, which have been torn away.

From these facts it is apparent that for the growing of orchid seedlings it is absolutely essential that an association of the seed with the proper root-fungus be brought about. In practice, this has often been accomplished by the sowing of the seeds on pots containing the parent plants. This method, however, has many disadvantages. The plants cannot be repotted while the seedlings are growing, and the seeds are likely to be washed away in watering, since they cannot be readily protected by a proper covering. Better success can be secured by the use of straight-walled glass jars with loose glass covers. These are filled with finely chopped sphagnum, which is well pressed into the jar. The whole is then sterilized in a steam-box for one hour on three successive days in order to kill bacteria and spores of molds which are likely to overrun the seedlings. After sterilization, the jars should be allowed to stand for a few days. Those in which molds develop should be discarded. The sterile jars may then be inoculated with the root-fungus from the species of orchid to which the seed-plant belongs. For this purpose, portions of infected roots should be cut into small pieces with a sterile knife and scattered over the sphagnum seed-bed. Great care should be observed at all times to avoid the introduction of foreign spores from the air. It should also be borne in mind that only the covered roots contain the fungus, and that generally only the soft tissues from ½ to 1 inch back from the root-tip are most abundantly infected. As soon as the root-fungus has grown through the sphagnum, the seeds should be sown in the jars. In the collection and handling of the seeds, all possible precaution should be taken to prevent contamination.

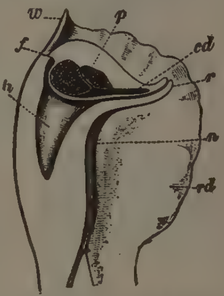


2650. The pendent anther in Cœlogyne speciosa.

While the difficulties involved in these manipulations are considerable, they are not insurmountable, and it is not unlikely that in time means will be found to remove many of the uncertainties which at present attach to the growing of orchid seedlings. With the increasing demand for orchids for cut-flowers and for general florists' use, and the depletion of the sources of supply of imported orchids,—especially of the rarer endemic varieties,—the growing of seedlings will become more and more a matter of necessity. The production of new and improved varieties, and the preservation and multiplication of rare sorts will be greatly facilitated when the growing of seedlings is freed from its many uncertainties. The seed-grown plants have many advantages over the imported ones. They are from the start better adapted to greenhouse conditions. They are hardier and more resistant and can be grown into plants of better form. They also flower more freely and often can be made to bloom twice a year.

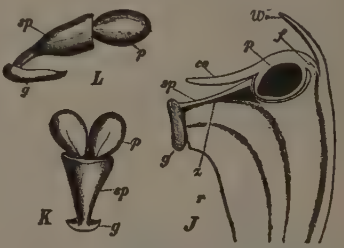
Hybrids.

One of the most fascinating phases of orchid-culture is the production of hybrids. By the crossing of different genera and species, numerous new orchids have been produced, many of which are superior to the native species. The first orchid hybrid to be produced in cultivation was *Calanthe Dominii*, a cross between *C. masuca* and *C. furcata*. It was raised by Mr. Dominy in the nursery of James Veitch & Son, and flowered in 1856. Other hybrids, including the beautiful *Calanthe Veitchii*, appeared in the following years, and in 1861 the same grower produced the first bigeneric hybrid, *Goodyera Dominii*, which was a cross between *Hæmaria* (*Goodyera*) *discolor* and *Dossinia marmorata*. Since that time the interest in orchid hybridization has grown greatly. The number of orchid hybrids now is between 3,000 and 4,000. Rolfe and Hurst record twenty-three genera which have entered into bigeneric hybrids, and many cases in which three genera have entered into the hybrid. In some hybrid genera, like Læliocattleya, the forms far outnumber the species of the parent genera.



2651. Column of Phaius cupreus.—*h*, cavity below the anther; *f*, filament; *p*, pollinia; *cd*, caudicle; *r*, rostellum; *n*, stigma; *w*, petaloid extension of the dorsal part of the column continuous with the lateral wings, *rd*.

The pollination of orchid flowers requires a little skill and patience and a knowledge of the parts of the flowers described earlier in this article, but otherwise offers no great difficulties. Only strong and vigorous plants should be chosen for seed-bearing, since the process greatly exhausts the plant and sometimes even causes its death. The pollinia are mature and the stigmas are receptive when the flower is fully open. When it is the purpose to produce hybrids, it is well to remove the pollinia of the plant that is to bear the seed since the possibility of accidental interference by the plant's own pollen is thus prevented. Even when it is intended merely to grow non-hybrid seed, this course is to be recommended, since, in nature, the orchids are habitually cross-pollinated. The pollination is easily accomplished. To this end, the pollen-masses are removed from the anther by means of a sharp lead-pencil or a pointed stick and placed on the stigmatic surface. In the Cypripediums and related genera, the pollen-masses are exposed, but in most of the other orchids the pollen is covered by the anther, which can be readily removed. The pollinia can be picked up by



2652. J, column of Cochlioda sanguinea; *w*, dorsal extension of column; *f*, filament; *p*, pollinium; *co*, extension of filament; *sp*, stipe; *g*, adhesive disc; *z*, disorganizing tissue by means of which the stipe and adhesive disc are separated from the rostellum. *K*, two pollinia with stipe and adhesive disc; *L*, lateral view of same.

touching the adhesive disk with the stick or lead-pencil. Usually several pollen-masses will be thus withdrawn, but as a rule it is best to place only a single one upon each stigma. Fewer seeds are thus ripened but these are better nourished and produce more vigorous seedlings than seeds from full capsules. The methods of sowing the seed are the same as already described.

The nomenclature that has been most frequently adopted (aside from treating them as direct species names) for simple orchid hybrids between two species of the same genus consists in the application to the hybrid of a Latin name of specific rank but preceded by a ×. Thus *Calanthe × Veitchii* signifies that the plant so named is a hybrid between two species of Calanthe. Sometimes non-latinized names are used, as Cattleya × "Nymph." In the case of bigeneric or trigeneric hybrids, the name of the hybrid is usually formed by the combination of parts of the names of the parents or of the whole name of one parent and part of that of the other, as Epiphronitis (Epidendrum and Sophronitis), Læliocattleya (Lælia and Cattleya), Brassocattlælia (Brassavola, Cattleya, and Lælia). These are written as one word without hyphens or capitals at the beginning of the second or third parts. For further details concerning orchid hybrids and lists of all known forms, see G. Hansen, "The Orchid Hybrids," London, 1895; E. Bohnhof, "Dictionnaire des Orchidées Hybrides," Paris, 1895; R. A. Rolfe and C. C. Hurst, "The Orchid Stud-book," Kew, 1909, and Sander & Sons, "Orchid Hybrids," St. Albans, 1912 (?). For other suggestions on the nomenclature of orchid hybrids, see the entries *Adamara*, *Linneara*, *Lowiara*.

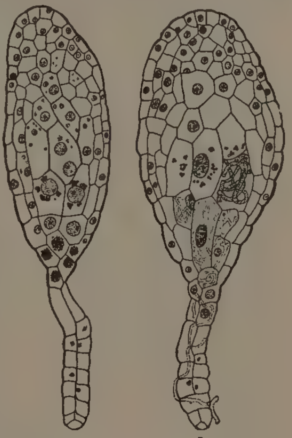
Foliage plants.

The Physureæ, a small group of orchids distributed in tropical Asia and the Malay Islands, with a few species in Africa and North America, are remarkable for their beautifully variegated leaves (Physurus, Anœctochilus). The plants themselves are usually small, with the habit of Goodyera, a North American representative of the group. Variegated or mottled leaves occur also in some other groups (Cypripedium, Goodyera, Phalænopsis, and Oncidium).

Historical sketch.

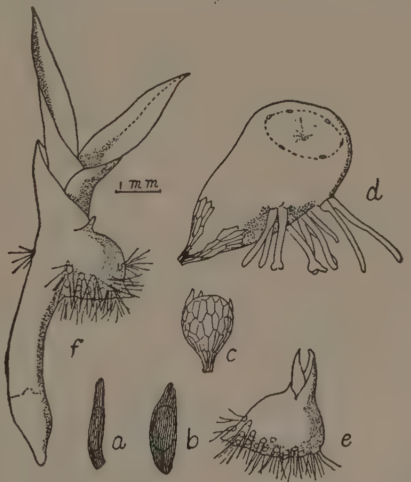
While the native orchids of Europe excited the interest of the herbalists of the sixteenth century, the epiphytic forms of the tropics did not become known to botanists until a much later period. By the end of the seventeenth century, a few species had been described and figured by Rheede tot Draakenstein, Sloane, Plumier, and others. In the second edition of Linnæus' "Species Plantarum" (1763), thirty species of epiphytic orchids are described under Epidendrum, which, at that time, was made to include all epiphytic orchids from the tropics. In 1805, Willdenow, in his edition of the "Species Plantarum," listed 391 orchids, including 140 epiphytic species. In the nineteenth century, through the exertions of many collectors, the number of known tropical orchids rose rapidly. For the descriptions of the numerous forms coming in during that time we are chiefly indebted to efforts of Lindley and of Reichenbach.



2654. Embryos of a Læliocattleya. *a*, not infected; *b*, infected.

Attempts at the cultivation of tropical orchids apparently did not begin until early in the eighteenth century. The first edition of Miller's "Gardener's Dictionary," in 1731, describes twenty native European species under Orchis, but no tropical form is mentioned. About this time, however, plants began to be introduced into English conservatories by missionaries and officers who visited the tropics. In 1731, *Bletia verecunda* was received from the West Indies. The vanilla was cultivated by Miller in 1759, and was at that time fairly well known in English conservatories. In 1789, Commodore Gardner sent plants of *Epidendrum fragrans* from the woods of Jamaica. One of these flowered two years later and was the first orchid figured in Curtis' "Botanical Magazine," plate 152 (as *E. cochleatum*). In Martyn's edition (1807) of Miller's "Gardener's Dictionary," 124 orchids, including the vanilla, were listed under Epidendrum.

The middle part of the nineteenth century is remarkable for the great number of new and rare forms introduced, and for the large sums often paid for striking novelties. As early as 1855, a plant of *Aërides Schroederi* brought something over $430 (G.C. 1855, page 775). In 1875, a plant of *Dendrobium Wardianum* was sold at Stevens' auction rooms for over $500 (G.C. 1875,



2655. Seedling of Odontoglossum.—*a*, seed; *b*, same somewhat swollen; *c*, same bursting testa; *d*, young spherule with root-hairs; *e*, more advanced stage showing cotyledon and first leaves; *f*, seedling with root and leaves developed.

I, page 502), and in the same year at the sale of the collection of John Russell at Mayfield a plant of *Saccolabium guttatum* sold for $313, one of *Saccolabium Russellianum* for $141, and an *Oncidium splendidum* for about $150 (G.C. 1875, II, page 467). In 1879, a fine plant of *Vanda cærulea* sold among other orchids of a large collection for about $460 (G.C. 1879, I, page 27). These are only instances with which the records of that period are replete. Although such prices were realized only for exceptional plants, there was always a large demand for good plants of all types, for which considerable sums were paid. The prospects of great reward caused collectors to scour every part of the tropics, risking their lives in the mountains, jungles, and fever-haunted swamps. Vast numbers of plants were imported and many died on the voyages, or subsequently, for want of rational treatment; but the large importations served to popularize the plants and to increase the demand for them. In time the climatic conditions under which they grew in their native regions became better known, and the plants were treated more in accordance with their requirements. Fewer orchids are imported at the present time, for the rewards are not so great as formerly, and other means for multiplying the stock are supplanting importation to a great extent. Yet the interest in orchids is not abating, but is steadily becoming more widespread. Although the large collections of fanciers are not so distinctive of orchid-culture as formerly in this country, the use of the plants is becoming far more general. The flowers have become a regular part of the florist's stock and thousands are annually sold in the markets. The ease with which they are grown, their great range of fine colors, and the wonderful keeping qualities of the flowers insures them an ever-increasing popularity.

Literature.

A large and special literature on orchids has grown up. Many magnificent folios and smaller works have been devoted to the illustration and description of these plants. Notable among these are "Sertum Orchidaceum," by J. Lindley, London, 1838, a large folio containing forty-nine colored plates of East Indian orchids; "The Orchidaceæ of Mexico and Guatemala," by J. Bateman, London, 1837–1843, an even more sumptuous work, with forty plates, of which only 125 copies were published; "A Monograph of Odontoglossum," London, 1864–1870, by the same author; "Pescatorea," Brussels, 1860, by J. J. Linden; "Reichenbachia," St. Albans and New York, 1888–1890, second series 1892–1894, by F. Sander, folio, two volumes, with ninety-six colored plates; "A Century of Orchidaceous Plants," London, 1849, by W. J. Hooker, a quarto volume containing 100 plates selected from Curtis' "Botanical Magazine," "A Second Century of Orchidaceous Plants," London, 1867, by J. Bateman, contains 100 plates of reproductions from the same work; "Xenia Orchidacea," Leipzig, 1858–1900, by H. G. Reichenbach, three quarto volumes containing 300 partly colored plates; "The Orchid Album," London, 1882–1897, by Robert Warner and B. S. Williams, eleven quarto volumes, containing 528 plates; "Illustrations of Orchidaceous Plants," London, 1857, by T. Moore, contains 100 plates selected from the "Botanical Register" and Sweet's "British Flower Garden;" "Dictionnaire Iconographique des Orchidées," Brussels, 1897–1907, by A. Cogniaux and A. Goosens, eight volumes of colored plates of flowers; and "Orchids, the Royal Family of Plants," Boston, 1885, by Harriet S. Miner, contains twenty-four plates with a popular account. Two periodicals, "L. Orchidophile," Paris, 1881–1892, and "Lindenia," Ghent, 1885–1906, were almost wholly devoted to the illustration of orchids, while "The Orchid Review," London, 1893, and continuing, is a more popular journal devoted to the interests of orchid-culture in general. Many plates and descriptions of orchids have appeared in other serials like Curtis' "Botanical Magazine" and Lindley's "Botanical Register." Many of Reichenbach's species were described in the "Gardeners' Chronicle." A great many large manuals and handbooks have been published. Among them may be mentioned "A Manual of Orchidaceous Plants Cultivated under Glass in Great Britain," by James Veitch & Sons (A. H. Kent), London, 1887–1894, a very comprehensive manual of two volumes, containing many engravings; "Orchids: Their Culture and Management," by W. Watson, London, 1890, new edition, New York, 1903, with twenty colored plates and numerous engravings; "Les Orchidées Exotiques et Leur Culture en Europe," by L. Linden, A. Cogniaux and G. Grignan, Brussels, 1894; "The Orchid-Grower's Manual," by B. S. Williams, seventh edition, London, 1894, a large manual with numerous illustrations; and "Die Orchideen," by R. Schlechter, Berlin, 1914, 1915, a comprehensive handbook and manual giving the most recent taxonomic treatment of the cultivated orchids. Besides these larger works suited to the technical needs of the cultivator, a large number of popular works have appeared. Among these are: "Orchids for Everyone," by C. H. Curtis, London and New York, 1910, a beautifully illustrated popular handbook; "Woodlands Orchids," by F. Boyle, London, 1901, a popular account of orchids with stories of their collecting; "The Book of Orchids," by W. White, London and New York, 1902; "Culture of Greenhouse Orchids," by F. Boyle, London, 1902; and "Orchids," by J. O'Brien, New York, 1911; "Our Native Orchids," by W. H. Gibson, New York, 1905, a popular account, with illustrations; and "Lilies and Orchids," by Rosina C. Boardman, New York, 1906, contains color-sketches of seventeen native species. Among the works of a more technical and monographic character containing plates of orchids should be mentioned "The Orchids of the Sikkim-Himalaya," by Sir George King, Calcutta, 1898, 448 engraved plates (in "Annals of the Royal Botanic Garden," Calcutta, Volume VIII); "Icones orchidearum austro-africanarum extra-tropicarum," by H. Bolus, London 1893–1911, 250 partly colored plates with descriptions; "Orchidaceæ," by O. Ames, Boston and New York, 1905, five fascicles giving illustrations and descriptions of new or recently described species which had been inadequately figured up to the time of the appearance of the work; and "Die Orchideen von Java," by J. J. Smith, Leiden, 1905–1914, one volume, text and one volume plates. Finally may be mentioned the work of F. A. Bauer, "Illustrations of Orchidaceous plants," London, 1830–1838, an account with thirty-five colored plates showing the structure and morphology of the various genera.

The illustrations accompanying the present article are in part borrowed or adapted from German sources, as follows: Figs. 2631, 2638, 2650, 2651, 2652, from Pfitzer in Engler & Prantl's "Die Natürlichen Pflanzenfamilien," II. 6; Figs. 2625, 2626, 2627, 2630, 2632, 2633, 2634, 2641, 2643, 2644, 2645, 2646, from Pfitzer in Grundz. einer Vergl. Morph. d. Orch., and Morph. Studien ü. d. Orchideenbl.; Fig. 2653 from J. G. Beer, Betr. Morph. u. Biolog. d. Orch.; Figs. 2654, 2655, from Burgreff, Anz. Tropisch. Orch. Samen.

Heinrich Hasselbring.

The general culture of orchids.

In the early days of orchid-culture, the treatment of the plants under glass was imperfectly understood, and with the meager knowledge of the natural conditions surrounding them in their native habitats, little successful progress was made for many years. The few cultural directions to be found were in works of foreign publication, scarcely applicable to plants grown in houses in America, where the winters are severe and changeable and the heat of summers more intense and less humid, necessitating a different mode of treatment. With a more satisfactory understanding of their requirements, orchid-culture here has made rapid advance in recent years, and most of the best collections have come into existence, many of which offer a very favorable comparison in fine well-grown specimens with those of the Old World.

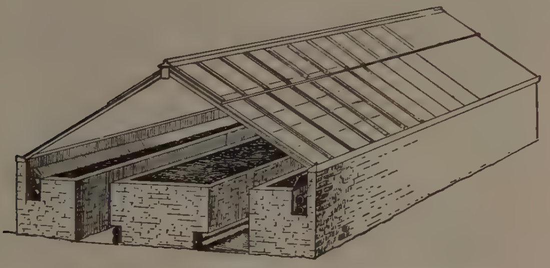
Orchid houses and their construction.

Various are the opinions of cultivators regarding the proper construction of orchid houses to secure the best results. Forty or more years ago many fine specimens of orchids were grown without a special house, along with general stove and greenhouse plants, and many good plants are still found cultivated in this way, but where a general collection of orchids is grown, four separate houses or divisions will be found necessary to obtain the best results. These are known as the "East Indian," "Brazilian," "Mexican" and "New Granadan," or odontoglossum departments. This is the older terminology, but it represents a good cultural classification.

The East Indian department requires a winter temperature of 65° to 70° F. by night and 70° to 75° F. by day; a few degrees' rise with sun heat will do no harm. The temperature should be gradually increased 10° toward midsummer and gradually decreased toward late fall. This is the warmest house and is used for the cultivation of aërides, angræcums, the warmer tropical cypripediums, phalænopsis, calanthes, dendrobiums and thunias while growing.

The Brazilian department should range in winter from 60° to 65° F. at night and about 70° F. in the day, allowing a few degrees more with solar heat, and a rise of 10° toward midsummer. This department is for bulbophyllums, cattleyas, warm epidendrums, Brazilian lælias, miltonias of the cuneata and spectabilis sections, *Odontoglossum citrosmum*, stanhopeas, and various genera and species requiring a like temperature.

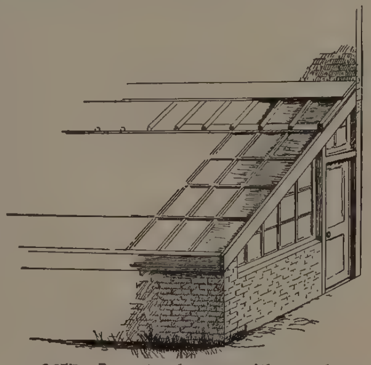
The Mexican department is used chiefly for the cultivation of *Cœlogyne cristata*, Mexican lælias, growing lycastes, anguloas and acinetas, many species of Maxillaria, a large part of the oncidiums and warm odontoglossums, phaius and allied species which require a few degrees lower night temperature and usually a little more sunlight to ripen their tissue for flowering than is afforded in the Brazilian department. It is also invaluable for resting dendrobiums and many other deciduous and terrestrial orchids.



2656. Section of a small, well-constructed orchid house heated by hot water.

The New Granadan (it might now be called the Colombian) or odontoglossum department must be kept as cool as possible in summer, and in winter should range from 50° to 55° by night and to 60° F. by day; it is used principally for masdevallias, odontoglossums, more especially *O. crispum*, and allied genera, disas, cool oncidiums, such as *O. ornithorhynchum* and *O. varicosum*, lycastes in warm weather, and many other individual species from high altitudes which require a cool house at all seasons for they suffer from the heat of our summer.

Styles of construction change, but the fundamental principle in building an orchid house is to secure a structure that can be easily heated and which has a naturally moist atmosphere without excavating deeply, for houses built much below ground lack circulation and almost always prove detrimental to orchid-culture. The houses (excepting the New Granadan house) should preferably be built to run north and south with an east and west exposure, in order that they may receive the benefit of the early morning and late afternoon sun, with the least possible heating effects from it at noonday, thus making little ventilation necessary; atmospheric moisture will be more easily retained in such a structure. The houses may be as long as required (with the potting-shed at the north end to avoid unnecessary shade and protect the houses in winter against severe north wind), and about 16 feet wide, which will allow side beds of 2½ feet each, two walks of the same width, and a center pit 6 feet wide. From floor to ridge should be 10 feet and to the eaves 4½ to 5 feet. Top ventilators should extend along both sides at ridge, thus affording protection from direct cold winter drafts in airing by using the sheltered side. Side ventilation is unnecessary and often injurious, the direct drafts causing plants which are out of condition to shrivel.



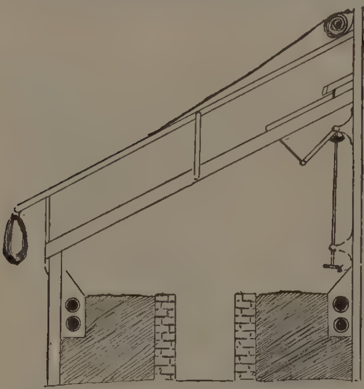
2657. Lean-to house with northern aspect for Odontoglossum crispum and other New Granadan orchids.

In glazing orchid houses, the glass should not be less than 12 by 14 inches, and larger if possible. It is also important that only the best quality procurable be used, free from lenses which burn the leaves when shading is removed. Plate glass is much to be preferred when it can be had, as it contains no lenses and gives a pure even light. If this is used a size about 16 by 24 inches will be found very serviceable. Poor glass should not be employed in any case, as it necessitates shading long before this is beneficial to the plants.

The outside walls should be built of brick or stone when possible, and the beds and pits within should be of the same material, 8 inches thick and about 3 feet in height, filled solid to the top, using stone or rubble for drainage in the bottom, following it up with finer material and finishing with an inch or two of fine gravel. Wooden benches may be used if desired, often with first-class results, by covering them 2 or 3 inches deep with ashes, sand or gravel, but the solid benches are more sure to give better satifaction. They give off moisture more gradually and offer a cool footing for the plant both winter and summer, which is essential and natural.

Good results will follow from either steam or hot-water heating when properly conducted. Unless the range of glass is large and a night fireman is kept, the old-fashioned method of hot water under natural circulation will be useful for orchid collections, using the regulation 3½-inch pipe, running the flows along the back beneath the eaves and returning along the floors beneath. (See Fig. 2656, which fairly illustrates an acceptably constructed house.) The quantity of pipe required for heating a house depends upon the location and degree of heat desired. A slab or board should be placed along the back of the side beds to throw the heat against the eaves and protect the plants from direct heat before it has assimilated the moisture of the house.

The New Granadan house should be a lean-to structure of northern aspect, with a wall of stone or brick along the south side to protect it from solar influence as much as possible (see Fig. 2657). The glass should be protected by canvas roller shades raised 15 or 20 inches above the glass on framework. One side of the canvas should be tacked along the top of the house, and the other to a round wooden roller 3 or 4 inches in diameter and as long as convenient to draw up; the two ropes should be fastened to the ridge, carried down beneath the shade around the roller, and up over the top to a single pulley near the ends; thence through a double pulley in the center and down over the top of the shade to the ground. By these ropes the shade can be raised and lowered in cloudy and bright weather at will. (See Fig. 2658.) Solid beds and piping similar to the other orchid houses can be used, or as in Fig. 2658; viz., a flow and return down each side connected with valves so that either or both sides may be used as desired.



2658. Cross-section of New Granadan orchid house to show solid beds and methods of heating and shading.

Shading of some sort on the glass is necessary for all orchid houses from early February until November, and in some cases also in the winter months, to protect the plants from the sun. It may be of canvas, as in Fig. 2659, or consist of whitewash or paint applied directly to the glass. Whitewash made from fresh lime is perhaps the best to use, as it is easily removed in autumn. The first application in February should be light, following it with a second coat a month later, and, if necessary, a third in July. This will wear off gradually and in most cases should be entirely removed in December. It is easily removed with a stiff brush. There are also patented shadings.

The two great horticultural groups.

Orchids are horticulturally divided into two large sections: terrestrial and epiphytal, the former embracing those that grow on the ground and derive their nutriment more or less directly from it; and the latter those that usually attach themselves to rocks and trees, and derive a greater portion of their nutriment from the atmospheric gases and accidental deposit of decaying leaves, or grow among the various ferns and vines, which grow in abundance on the rocks and trees of the moist, wooded tropics, absorbing the various elements of their slowly decomposing humus.

Terrestrial orchids grow at various altitudes, and are widely distributed throughout both hemispheres, the polar regions and arid deserts excepted. Many are deciduous and tuberous-rooted; some grow from underground rhizomes; others are pseudobulbous and deciduous, while not a few have reed-like stems. Examples of terrestrial orchids are catasetum, calanthe, cyrtopodium, most cymbidiums, some of the cypripediums, disa, goodyera, govenia, habenaria, lissochilus, many masdevallias, microstylis, neottia, orchis, pogonia, peristeria, phaius, sobralia, spathoglottis, all of which should be sought under their special genus headings in other portions of this work for cultural directions. They differ very essentially in structure, and in many cases require a special method of treatment for individual plants of the same genus, as Habenaria for example, where some are found growing in rich, turfy loam exposed to sun, while others inhabit wooded, swampy locations.

Many species of terrestrial orchids nearly or quite defy successful treatment under cultivation from lack of knowledge regarding the mineralogy of their native habitats, or from the plants being practically saprophytic on certain species of decaying vegetation, or growing only in connection with the mycelium of special fungi, which may assist them in making proper growth.

The hardy species, when a general collection is grown, should be cultivated in pots in coldframes, as many need protection during winter and others require shade which can be supplied by painting the glass. Our native hardy species, however, do best planted out in a properly constructed rockery, laid out in pockets so that each may receive its proper compost.

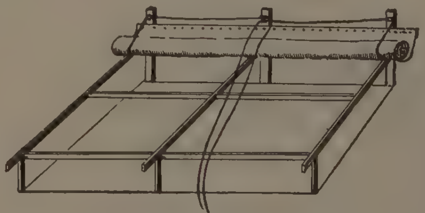
The more tropical species—cymbidiums, cypripediums such as *C. insigne*, *Phaius grandifolius*, *P. maculatus* and *P. Wallichii*, sobralias and some other evergreen species—thrive best in the Mexican or cool end of the Brazilian house.

Anæctochilus, tropical goodyeras and cypripediums, spathoglottis, and several genera of like nature, require the same general treatment as epiphytal orchids, with temperature of the East Indian department at all seasons.

Bletias, catasetums, cyrtopodiums, calanthes, many lycastes, tropical liparis and microstylis, *Phaius Humblotii* and *P. tuberosus*, thunias and many other deciduous and semi-deciduous species, should be grown in the East Indian, or warm end of the Brazilian department, and during the resting period should be placed in the Mexican department, allowing them only sufficient water to keep the plants in sound condition.

Epiphytal orchids are found chiefly in the humid forests of tropical countries, often along streams where they receive their moisture in the dry season. A few grow in open grassy situations or among brush. These consist chiefly of climbing epidendrums of the *E. evectum* section, a few oncidiums of the caulescent type (the distance between the pseudobulbs often denoting a year's growth), and some of the terete vandas, and others.

Aërides, phalænopsis, vanda and the epiphytal cypripediums are distributed throughout India, Malay Peninsula, Cochin-China, Celebes, Borneo, Philippine Islands, Java and some of the Oceanic islands, usually following the moist forests of mountain ranges, occasionally at high elevations. With one or two exceptions, as *Vanda cærulea*, all do satisfactorily in the East Indian department, reserving the warmest part for phalænopsis, which, as a rule, grows nearest the sea-level.



2659. Method of shading orchid houses.

Angræcums are natives of Madagascar and tropical Africa, with one isolated species, *A. falcatum*, which is from Japan. They grow in humid, shady locations, where they can receive a copious supply of water at all seasons, and are closely allied to vanda, requiring the same general temperature and treatment.

Dendrobiums are most common throughout India, Moulmein being a central district, but they are also plentiful and widely distributed throughout eastern Australia, New Guinea, the islands of the west Pacific and Oceanica under various climatic conditions. The larger part of them, especially the deciduous species, are subjected to long droughts and long resting periods, but as they lose their foliage at that time their evaporating surface is reduced to a minimum, and the effect of the dry heat through the day is more than counteracted by heavy dews and the condensing vapors which arise in the early mornings in those countries.

Bulbophyllums and cœlogynes have their homes principally in the mountainous forests of East India and Borneo, where they are copiously supplied by frequent rains. Nearly all grow best in the Brazilian department.

Cattleyas and lælias inhabit the humid forests of the various mountain ranges of tropical America, from Mexico south through Colombia to Peru, the North Amazon Valley, through Venezuela and Guiana, and the mountain belt of eastern and southern Brazil, usually at an altitude of 2,000 to 5,000 feet, excepting the Mexican species, *L. albida*, *L. anceps*, *L. autumnalis* and *L. majalis*, which grow at 5,000 to 8,000 feet, commonly among polypodium fern.

Cattleyas and lælias grow on rocks and trees often devoid of other vegetation along the margins of rivers and ravines, usually in shade, where they receive a copious supply of water from heavy dews and condensation of morning fogs which saturate the forests during the dry season, and often excessive rains while growing. They should be grown in the Brazilian department, excepting *Cattleya citrina*, the Mexican lælias and *L. Jongheana*, which thrive best in the Mexican department or warm end of the New Granadan house.

Stanhopeas are found from southern Mexico south to Peru, Venezuela, Guiana and Brazil at rather low elevations, often in dense forests, the individual species having a very wide range. The Brazilian house affords them the best temperature, but they may be grown in any of the departments with success.

Epidendrum is a large and varied genus, widely distributed throughout tropical America and in the United States from South Carolina southward, and one of the few epiphytal genera inhabiting the United States. They are found at all elevations from sea-level to 10,000 feet or more. The writer found *E. ibaguense* growing in quantity on the margin of perpendicular clay ridges fully exposed to the sun at this altitude in the United States of Colombia in a robust, healthy state, and the same species below 5,000 feet in the same condition. Many of the individual species cover a wide range of distribution. They require the same general treatment as lælias and cattleyas. Few species are worthy of cultivation except for botanical purposes.

Maxillarias cover much the same range as the last genus, but are not quite so widely distributed. They grow equally well in either the Brazilian or Mexican departments.

Oncidiums are distributed along the mountain ranges from southern Mexico to Peru, in the southern and norther portions of Brazil, chiefly along the coast, the Spanish Main and islands of the Caribbean sea. The *O. carthaginense* and *O. Papilio* sections are found at sea-level and seldom above 500 feet elevation. These grow best in the Brazilian house. Nearly all of the other species may be grown in the Mexican department, except a few, such as *O. cucullatum*, *O. Phalænopsis* and the *O. macranthum* section, which are found at high altitudes; these should be grown in the New Granadan department.

Odontoglossums follow the higher wooded mountain ranges from southern Mexico, Cental America and the Central Andes of Colombia south to Peru and the northwestern portion of Venezuela, all at high altitudes. They usually grow in the moist shady forests, where the rainy season is long continued or condensing fogs and dews are very heavy, keeping many of the species in an almost perpetual state of saturation, their only relief of excessive moisture appearing to be from the frequent heavy winds that prevail in these regions. The Mexican species grow well in the cool end of the Mexican department, while those of the *O. luteo-purpureum* and *O. crispum* type require the New Granadan house.

Lycastes are distributed from southern Mexico to Peru along the mountain ranges, usually at an altitude of 4,000 feet in rather shaded locations; they are most common from southern Colombia to their northern limit. *L. tetragona* is from southern Brazil and far removed from the general area of distribution, with little resemblance to any other species. Its 4-angled monophyllus pseudobulbs produce semi-pendent scapes carrying often as many as eight flowers, not unlike a cymbidium in general appearance. Lycastes grow well in either the Mexican or New Granadan department.

Selenipediums are the South American representatives of cypripedium. They are distributed from Costa Rica south to Bolivia, through Venezuela, Guiana and eastern Brazil, from 3,000 to 8,000 feet elevation, in wet marshes and on the branches of trees in shaded forests, in all cases where they get a bounteous supply of water at all seasons. The Brazilian or Mexican department suits them equally well.

Masdevallias, restrepias, and pleurothallis grow at high elevations in Venezuela, Mexico and south to Peru, with a few in the Organ Mountains of Brazil, their principal center being Colombia near the odontoglossum district. They always follow the mountain ranges, growing on trees, rocks and on wet, marshy slopes, in extremely wet locations. The chimæra section is found at the lowest elevation. They all grow best in the New Granadan department.

Newly imported orchids.

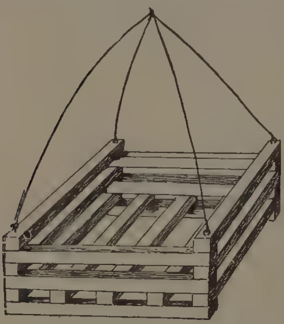
On arrival of cases of orchids from their natural habitats, they should be carefully unpacked as speedily as possible, in an isolated room where insect pests that often arrive in the cases may be destroyed, and laid carefully and loosely against one another, on the bench of a shady well-ventilated house or packing-shed. Should they all be found in good condition, the pseudobulbous species, such as cattleyas and lælias, should be hosed over thoroughly and allowed to remain for about a week, at the end of which time they should be examined for any signs of decay and bruises. All such parts should be removed with a sharp knife. The plants should be cleaned and sponged to remove dust, potted or basketed, as the case requires, and placed in a shady portion of their respective departments, allowing them sufficient water gradually to start them into action, after which time they will require the same treatment afforded established plants of their kind.

Cypripediums, masdevallias, phalænopsis, vandas, the batemannia and bollea sections of zygopetalum and other non-pseudobulbous genera should be placed on damp sphagnum in a well-shaded airy department for a week or ten days, without syringing, until it is ascertained what amount of damage they have received in transit. After sponging the leaves carefully and removing any decayed and bruised parts, they may be potted and basketed, and removed to their proper quarters, watering sparingly until they start new action.

It is customary in some establishments to hang newly imported orchids by the roots, tops down, from the roof of the house or beneath the benches until they show signs of new action, but they invariably suffer more or less from this practice and are better treated as above.

Pots, baskets, and supports.

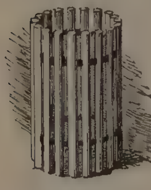
Many orchids are best cultivated in the ordinary earthen pots and pans, more especially terrestrial species and a few of the epiphytal kinds, which grow on rocks in marshes, and among quantities of humus and fern roots. Most of the epiphytal species, however, need special structures that will admit air to circulate freely to the roots; otherwise, these are liable to decay through excess of water if confined in close pots when inactive in winter, which must eventually weaken the constitution of the plants.



2660. Commonest and best style of basket for general culture of orchids with pendulous scapes.

The best and most practicable pots and baskets are shown in Figs. 2660 to 2661. Fig. 2660 shows the orchid basket most commonly used; it is the best adapted for the general culture of cattleyas, coryanthes, dendrobiums, epidendrums, lælias, masdevallias of the chimæra section, oncidiums, and most orchids with pendulous flower-scapes. They may be made of cedar, teak-wood, cypress, or any durable wood. The wood is cut into square (or round) sticks of any length desirable and in proportionate thickness from ½ to 1 inch, and carefully perforated at each end. Through the holes is inserted a strong wire, which is looped at the upper end when finished in order to receive the wire hanger. These baskets may be as deep as desired, but three sticks on each of the four sides are usually enough for most orchids, with two or three placed crosswise through the bottom, to hold the compost. The hanger is made by twisting together and bending down in the middle two pieces of galvanized or copper wire, thereby forming four ends to insert in the basket-loops and a loop or hook at the top by which to suspend it.

The orchid cylinder (Fig. 2661) is very useful for standing on the bench or pit, and is used for renantheras, aërides, vandas, angræcums, epidendrums, and many other tall plants that are too tall or difficult to suspend. Cylinders are made in all sizes and any diameter desired, with either square or round sticks. They are bored a short distance from the ends and a wire inserted through them, with a small block between each stick, to make an opening for air. When large enough the sides are brought together and fastened. The depth is adjusted by movable cross-pieces.



2661. An orchid cylinder, used for very tall species.

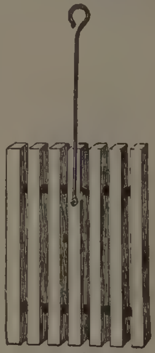
The orchid raft (Fig. 2662) is made in much the same way as the cylinder, but is left flat with the openings between closer together. Oblong-square blocks of hard, rough wood, an inch or less thick, answer much the same purpose. The orchid raft or block is very useful for many species, such as *Cattleya citrina*, barkerias, *Epidendrum falcatum*, *Dendrobium Jenkinsii*, *Oncidium Limminghii* and *O. Papilio*, scuticarias and the like.

The earthen basket (Fig. 2663) is useful when the compost is fine and when the roots do not require much atmospheric action; also properly to mature tissue in a few terrestrial species, thereby inducing them to flower more freely. The earthen basket is especially useful for acinetas, peristerias with pendulous scapes, stanhopeas and others; it is made with ovate openings around the sides and a round one in the center to admit pendulous scapes.

The perforated pan (Fig. 2664) is usually made only in small sizes and used for bulbophyllums, the concolor type of cypripedium, dendrobiums, and many other small-growing species that do well suspended from the roof.

The perforated orchid pot (Fig. 2665) is for bench use and is useful for many epiphytal orchids that are not to be suspended, the perforations or holes supplying abundant air to the roots, a safeguard against losing them through overwatering in winter.

Figs. 2666 and 2667 show the standard earthen pot and pan for terrestrial species. They should have the drainage holes made on the side at the base, instead of directly underneath, as a preventive against earthworms entering from the benches.



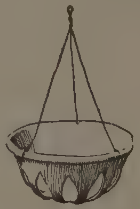
2662. An orchid raft, used for much the same purpose as the cylinder.

Potting of terrestrial orchids.

Terrestrial orchids as a rule grow best under pot culture. Potting material for the following genera—acanthephippium, bletia, calanthe, cymbidium, *Cypripedium insigne* and most of the hardy species, cyrtopodium, habenaria, liparis, microstylis, peristeria, phaius, pleione, sobralia, thunia, and some others—should consist of about one-third each of chopped sod with some of the fine soil removed, chopped live sphagnum and leaf-mold, adding a little ground bone for some of the strong-growing kinds. One-third of the pot space should be devoted to clean drainage, covered with sphagnum or rough material to keep it open. After removing all decayed parts, the roots should be carefully distributed and the compost worked in gently but firmly around them, leaving the surface a little convex and slightly below the rim of the pot as in Fig. 2666 (the dotted lines denote drainage required). The convex surface gives the rhizome an opportunity to dry out frequently, thus avoiding fungi, which are troublesome to some species.

In repotting terrestrial orchids, sufficient pot room should be given to last a year or two if possible, as they dislike to have their roots disturbed oftener than is necessary. The best time to repot is just before the rooting period, or when they are starting their new growths in spring. The deciduous species of calanthe can be easily increased at this time, if desired, by removing the old bulbs and placing a number together in a pan or shallow box, covering them partly with compost and placing them in a warm house until they start action, after which time they should be potted as desired, two or three together.

Anœctochilus, arpophyllums, cypripediums, disas, goodyeras, spathoglottis, and many allied genera, grow best under pot culture, but otherwise require compost and treatment similar to the epiphytal kinds.



2663. Earthen basket, for stanhopeas and other orchids, whose pendulous scapes issue through the holes in the bottom.

Potting, basketing, and compost for epiphytal orchids.

The roots of epiphytal orchids are usually very porous, and many are covered with a corky substance (velamen), capable of absorbing and retaining water for considerable time. In their native homes a great many of the roots are aërial or grow in loose, fibrous material, such as moss and the fine roots of polypodiums and other ferns, where they have free access of air at all times. It is important that they receive similar treatment under cultivation so far as is consistent with the difference of their environment taken into consideration. Thus it is apparent that one of the special features in the culture of epiphytal orchids lies in the proper selection of compost and the method of potting and basketing for the best results in after-cultivation.

Peat fiber, sphagnum moss and leaf-mold constitute the principal materials of good compost, usually lasting one or two years without renewal, which is important, as the roots suffer more or less in being disturbed. By peat fiber is meant the fibrous roots of various wild ferns, with the fine soil removed by first chopping it into small pieces, then rubbing it across a coarse sieve. The several species of osmunda furnish us with the best orchid peat. (See *Osmundine*, page 2414.) The sphagnum moss used for orchids should consist of *Sphagnum squarrosum*, *S. macrophyllum* and the coarse-leaved species only; *S. acutifolium* and other weak-growing species should never be used, as they soon decay and are detrimental to the roots.

2664. Perforated pan, adapted to small orchids that do well when suspended from the roof.

Leaf-mold is made from decomposed leaves. The leaves of almost any tree will do, but those of hardwood trees are most desirable, especially oak. When collected in the fall the leaves should be heaped up to decay for a year or more, and turned over at least twice within that time.

Charcoal is the best material to use for drainage and for mixing or interspersing with the compost. It is best made from hardwood and should not be overburned. Broken potsherds are often used, but they are not so good; being porous, they either absorb too much water at times or become over-dry too often and are liable to prove injurious. Charcoal is lighter in weight, and contains more useful properties.

Where closed pots are used, nearly one-half of the space should be devoted to drainage and the remainder to compost, consisting of about equal parts of peat fiber, chopped sphagnum and leaf-mold for most genera, adding a few pieces of charcoal in potting, and a piece beneath the rhizome of the tender ones. Care must be exercised in potting to distribute the roots properly and make the compost moderately firm about them, leaving the finished surface convex, to throw off surplus water and protect the rhizome from an overabundance of wet. Top-dressing with live sphagnum is beneficial to many orchids, such as *Odontoglossum crispum* and allies, and gives the surface a neat appearance. Fig. 2668 illustrates a finished pot, the dotted line in Fig. 2666 indicating the amount of drainage required.

When perforated or open-work pots or baskets are employed, no direct drainage is necessary. Rough, broken pieces of charcoal should be freely used in the compost while potting, as it helps to keep the mass firm and the roots of nearly all species attach to it freely; also it lessens the quantity of compost and so modifies its texture as to allow it to dry out more readily than when packed in a solid body.

2665. Perforated orchid pot, adapted to epiphytes which need plenty of air at the roots and are in danger of over-watering.

Cattleyas of the *C. intermedia* type, coryanthes, cypripediums of the *C. Lowei* and *C. Stonei* sections, some dendrobiums, *Oncidium carthaginense*, *O. crispum*, *O. macranthum*, *O. Papilio* and their allies should have the leaf-mold omitted, while aërides, phalænopsis, saccolabiums, vandas and kindred genera require only chopped live sphagnum and charcoal as a compost.

Watering, humidity.

It is impossible to lay down any hard and fast rules for watering orchids. Watering is a very important operation and requires more or less practical experience, connected with a knowledge of the general conditions surrounding the plants in their native homes. As a rule, most orchids need a liberal supply while growing, but the condition of the plant and compost and the manner in which it is potted or basketed have much to do with this.

The evergreen terrestrial species, which grow chiefly in loam fiber, as cymbidium, *Cypripedium insigne*, phaius, sobralias, and others, require water whenever the surface of the compost is becoming dry, with occasional light overhead syringing in fine weather, which will assist in keeping down red-spider, thrips and other pests. An occasional application of weak liquid cow- or sheep-manure is of great benefit while the plants are growing.

The deciduous species have a decided period of rest, at which time they are practically inactive and need very little water, enough only to keep the stems and pseudobulbs in sound condition. When growing, however, they require a good supply and should have a thorough watering to the bottom whenever the soil is becoming dry, but should not be kept in a wet condition at all times, or the soil soon becomes sour and infested with worms, under which condition no orchid can do well.

2666. Standard earthen pot for terrestrial orchids, with drainage holes at the side instead of at the bottom.

Epiphytal orchids, or a greater part of them, in their native habitats grow in locations where heavy rains are frequent or of almost daily occurrence in their growing season, and where condensing vapors settle on them like dripping rain, while the early morning fogs rise among the forests, charging the atmosphere almost to saturation in the early part of the day in the resting season. Such species as are subjected to a severe dry resting season are often deciduous (see *Dendrobium*, and also, page 2393). Many of the extremely alpine species, such as the masdevallias and *Odontoglossum crispum*, are subjected to two annual rainy seasons, and where these seasons are much prolonged it has been observed that the last-mentioned species in its native habitat mature as many as three pseudobulbs in the year. Thus the pseudobulb is no indication of annual growth, but a reservoir of supply in case the plant is overtaken by severe or sudden droughts, each pseudobulb being supplied with a mature secondary bud for further reproduction should the proper lead be destroyed.

2667. Standard earthen pan for terrestrial orchids, showing side drainage holes.

Such genera as aërides, cypripediums, masdevallia, vanda, and the like, which have no pseudobulbs, rely more or less directly on a daily supply at all seasons. These, with many of the extreme alpine species, should have a liberal supply of water at all times.

Many of the pseudobulbous kinds, including cattleyas and lælias, are also constantly in action perfecting new roots or maturing their flower-buds, after the pseudobulbs are completed and they are apparently at rest. For this reason careful observation of each species is necessary to make their cultivation successful.

Under basket culture, there is least liability of injury through overwatering, and excepting kinds like the oncidiums and dendrobiums (which need a dry and cool resting period to induce them to flower), and deciduous species at rest, nearly all should receive a good supply of water, weather permitting, whenever the compost is becoming dry, with frequent syringing overhead in fine weather, when the temperature is normal and ventilation can be given. A stimulant of weak sheep- or cow-manure applied occasionally to plants in action will benefit them.

2668. Method of potting an epiphytal orchid, showing the raised and round top of sphagnum.

On cold, cheerless days, when the temperature is below normal and the atmosphere is overcharged with moisture, very little watering or damping is needed, and unless it be some particular species which cannot endure drying, or tiny seedlings, it is safest to withhold water, as at these times the stomata cease action and the plants become overcharged with water; thus those with weak constitutions and immature growths are liable to attacks of wet-spot and rot. The best means of counteraction in such cases is to apply fire heat and ventilation. A close stagnant atmosphere is always to be avoided.

2669. Newly germinated seedling (Phaius hybridus).

As a safeguard against excessive changes in humidity, a hygrometer should be kept in each department to ascertain and regulate the degrees of moisture, especially during fall and winter. When overabundant, moisture can be reduced by applying fire heat and ventilation, and if insufficient by wetting down the paths and shelves, or pits, and reducing the ventilation. Well regulated departments should be kept as near as possible to 70° or 75° through the day or 80° to 85° with free ventilation, and about 80° at night. Just after damping and watering, it will often rise to 85°, but this is of no consequence, as it soon recedes. Orchids at rest, such as calanthes and dendrobiums, should be held at 65° to 75°. In no case, where it can be avoided, should it go below 60° nor rise above 90° for any length of time, as serious results are very liable to follow.

2670. Three months from seed, and ready to transfer to a pot. (Paphiopedilum insigne var. Sanderæ.)

Ventilation.

The ventilators should extend the entire length on both sides of the ridge, and be supplied with the best modern lifting apparatus. Extending them continuously along the roof necessitates raising them but a small height to afford proper circulation to the plants and egress of overheated air, without losing too much moisture. Having them on both sides assists in avoiding direct drafts, by using the side protected from the direct wind.

Air must be given at all times, when possible, to keep the atmosphere active, as well as to lower temperature, also to reduce the density of moisture when excessive in close, inclement weather and during the night. In bright weather ventilate enough to allow egress of the heated air.

It is customary with some cultivators to close down ventilators in wet weather and during the night to help retain heat. This is a serious mistake. It may show no visible injury in bright weather, when the density of moisture in the atmosphere is at a minimum, but this bad practice surely accounts for the decaying of many young growths, which are lost during wet, close and cloudy nights.

Propagation.

Many species of orchids can be propagated by division and by cuttings. This is usually resorted to when it is desired to increase the stock of rare and unique species and varieties. With the more common species, however, it is cheaper and better to buy freshly imported stock, if it can be had, as it often requires two, three or more years to bring the young plants up to the flowering stage.

2671. Eight months from seed. (Phaius Wallichii.)

The pseudobulbous species, such as cattleyas, odontoglossums, cœlogynes, are propagated by cutting part way through the rhizome three or more pseudobulbs behind the lead with a sharp knife. This will usually retard the sap and force the dormant eye behind the cut to grow. The back portion may then be removed and potted or basketed separately, or left on the plant to mature the new growth, and be removed when it starts action the following season.

With the deciduous calanthes, the old bulbs should be removed when potting them in spring and put, several together, in pans or flats and partly covered with sphagnum or potting compost until they start to grow, when they should be potted in the regular way. Thunias are easily propagated after the young growths are well advanced, by cutting the last year's stems into pieces 4 or 5 inches long and inserting the ends in chopped sphagnum and sand, placing them in the propagating-house until they grow, when they may have their normal heat. Dendrobiums are managed in much the same way, or the old canes can be laid on wet sphagnum, when many will produce new growths from the side eyes on the nodes. Aërides and vandas are increased by removing the upper portion with a sharp knife, leaving a few roots and at least a foot of stem to each top. The old bases of the stems usually break new growths freely, often producing several new shoots from each. Cypripediums should be divided between the older growths, leaving at least one old growth with each lead, and potted separately, allowing them a little extra moisture until they start to grow. Masdevallias and allied genera can be separated in the same manner, leaving several leaves and one or more new growths or leads to each piece. All species should be propagated at the commencement of the growing season.

Reproduction of orchids from seed.

The reproduction of orchids from seed through crossing and hybridizing has been conducted for many years successfully by a limited number of hybridists, principally abroad, and it is only within about twenty-five years that it has received much attention in America, but in that time very many beautiful hybrids have come into cultivation. Many of our establishments, both private and commercial, are now paying much attention to this branch of orchid culture, with varying degrees of success.

2672. A year from the seed. (Cattleya intermedia × C. labiata.)

The seeds germinate best when sown soon after maturity, and many lose their vitality in a few months if kept too dry and warm. When sowing the seeds, the best results are often obtained when they are dusted on the surface of pots or baskets containing a plant of the same genus as the seed and carefully watered with a very fine rose until they become attached, watching carefully for snails, slugs, and depredators in general that infest the compost. The pots or baskets should have a favorable-looking surface, with the compost in good condition, firm and free from fungi. Use pots or baskets that will not have to be disturbed for a year or more, as it often takes that length of time for the seedlings to come through. Seed sown in early spring seems to germinate soonest. The writer has had selenipedium seedlings up in three months from sowing, and again has waited for cypripedium twenty-three months before the seedlings appeared.

After the seedlings have perfected two or three leaves it is quite safe to remove them to small pots, singly, or several to a small pan, using compost of the same material as that for the parent, but cut a trifle finer. Many tiny seedlings are lost shortly after germinating, through the soil becoming sour or through fungi. When thus attacked they should be transferred to other pots or baskets not infested.

A newly germinated seedling of *Phaius hybridus* is shown in Fig. 2669. Fig. 2670 is of a three-months-old seedling of *Cypripedium insigne* var. *Sanderæ*, in proper condition to be transferred to a pot; Fig. 2671, eight-months-old plant of *Phaius Wallichii;* Fig. 2672 a twelve-months-old hybrid cattleya (*C. intermedia* × *C. labiata*); Fig. 2673 a cypripedium thirteen months old; Fig. 2674 a two-year-old hybrid between a cattleya and lælia (*C. intermedia* × *L. præstans*).

2673. Thirteen months from seed. (Cypripedium.)

The raising of orchids from seed shoud be encouraged, and should enlist the energy of every orchid-culturist, not necessarily for the production of hybrids, but also for the reproduction of rare species and varieties, and to save a number of species that are fast decreasing or becoming extinct in their native homes. Aside from the financial inducement offered the commercial grower, it will prove instructive to the botanist and afford pleasure and pastime for the amateur.

Diseases.

Orchids are subject to many diseases. Those having importance from a cultural standpoint and most troublesome to the grower are known as wet-rot, dry-rot and spot. Wet-rot is brought on by an overmoist or stagnant atmosphere, and is usually first detected by a semi-transparent appearance of the parts affected, which soon become dark brown. It spreads slowly along the tissue. If noticed at the commencement, it can be readily checked by slitting the epidermis with a sharp knife and removing the plant to a more airy position in the house for a few days.

Dry-rot is caused by a fungus which attacks the rhizome of the plant. It is often produced through burying the rhizome or base of the plant with compost. Cypripediums are subject to it. Large, healthy growths when attacked quickly show a sickly pale color in the foliage, which, on examination of the base, will be found discolored, and with a light brown appearance. If the portion attacked is quickly removed with a sharp knife it will usually give no further trouble; otherwise it will travel through the entire rhizome and destroy the plant in a very short time.

Spot comes from various causes: the appearance of small dark brown spots on the succulent leaves and pseudobulbs is usually an indication of cold and overwatering. Spot also arises through weak tissue, especially in phalænopsis, saccolabiums and angræcums during winter, which have been grown too warm, shady and moist. The affected parts should be slit with a sharp knife and a little flowers of sulfur should be rubbed over the wound. When they make new growth the plants should be placed in a brighter and more airy position to induce a better growth. The brown dots which make their appearance on the leaves, especially at the apices and on new growths of deciduous and plicate-leaved species, indicate either lack of sufficient water at the roots or an over-dry atmosphere, both of which conditions can be easily changed.

Snails and insects.

Orchids are attacked by many forms of snails. Insect pests are a great annoyance to the cultivator. They can be kept in subjection only by constant attention. Slugs and shell snails are very destructive. If allowed to increase they devour young shoots, roots and flower-buds. The best means of capturing them is to place saucers of dry bran on the shelves among the pots, and look them over morning and evening. By this means many will be destroyed. Various species of scale insects attach themselves to the leaves, pseudobulbs and rhizomes of nearly all species of orchids, and can be eradicated only by the use of a soft brush and washing with a sponge and water. A little whale-oil soap added to the water is of great assistance, and also useful in destroying red-spider, green-fly and yellow-fly. Black and red thrips attack the young growths of many species and often become very troublesome. Fumigating the houses with tobacco stems lightly about three times during the week will soon cause them to disappear. Fumigation is also a sure remedy for green-fly.

The cattleya fly is very injurious to young growths of cattleyas, lælias and some epidendrums. The flies lay their eggs in the very young growth at the base, causing an enlargement which is easily distinguished. The only remedy is to remove the growth and burn it. The mature fly can be eradicated by fumigating the house with tobacco stems about three times each week during early spring.

The dendrobium beetle larva burrows in the stems of various species of the genus, and is detected by a small discolored spot. There is no remedy, except to cut away and destroy the parts attacked. A pest much more to be dreaded is the dendrobium mite, which perforates the canes and rhizomes of dendrobiums and many other orchids, laying a number of eggs in each perforation. On hatching, these eat away a part of the plant around them, causing that portion to decay. They can be found only by careful and close observation, and this often after the plant is beyond redemption. There is no remedy but cutting them out, and unless the plant attacked is valuable it is best to burn it and keep the pest from spreading.

Mealy-bug is usually not very troublesome to orchids. It is readily seen and destroyed without much injury to the plant.

Roaches are usually very troublesome, and hard to eradicate, as they feed at night and remain hidden through the daytime. They destroy roots, growing shoots and young flower-buds and scapes. Bran, powdered sugar and paris green, mixed together and placed around the houses in saucers, will usually keep them in subjection, and they should be hunted down at night by the aid of a lantern. Many can be caught in this manner.

2674. Two-year-old hybrid between a cattleya and lælia.

Sow-bugs or wood-lice are usually common in every part of orchid houses, pots and baskets. They do a great deal of damage to young leaves, roots and the tender portions of flower-scapes. The paris green mixture used for roaches is very effectual in reducing their number, but it is impossible to be entirely freed from them.

Robert M. Grey.

Hardy orchids.

Many of our native species of orchids are very beautiful, and some are easy of culture, given suitable situations as to soil, moisture, and, in some instances, shade. It seems almost impossible to tame these wildlings, in the sense of making them border plants; the desirable situations are shady moist places in the woods for the habenarias, *Galeorchis* (*Orchis*) *spectabilis*, listera, and goodyera. Moisture, however, does not mean a stagnant condition of the soil, but slight depressions that are preferably above the level of surrounding soil, so that drainage is secure.

The two-leaved habenarias, such as *H. Hookeriana*, *H. orbiculata*, *H. blephariglottis*, and *H. dilatata* all occur in shady woods. One seldom finds more than an isolated specimen or two, but these may be easily transplanted after their flowering period, taking care to keep the fleshy tuber-like main root intact. *H. psycodes* is a bogplant and is often found in colonies, and this species is widely distributed. *H. ciliaris* grows in bogs in great numbers, and, when in bloom, the bright orange-colored flowers make a beautiful display in late summer. *H. fimbriata* is also a very showy bog-plant, enjoying the full sun. The arethusa often colors New England wet pastures a bright rose-purple in early summer where it is found in quantities very unusual in orchids; it requires very careful handling in digging when transplanting. Some of the soil should be dug with the plant to ensure its growing, and the same is true of the calopogon and pogonia, which also have pretty pink or purple flowers. Good success has been had in establishing colonies of goodyeras on shady banks; the three species, *G. repens*, *G. pubescens*, and *G. Menziesii*, which are very common in the North woods, have beautifully variegated leaves prostrate on the ground, and when in bloom are as pretty as the spiranthes, and a colony can readily be established.

The species of spiranthes are also easy to naturalize. It is found, however, that these plants appear to bloom biennially; one season the dry fields will be dotted with the pretty white flower-scapes, and the next year not one is visible. They have been dug in large numbers, but do not bloom the next year; it seems they require a year in which to recuperate. The common species are *Spiranthes gracilis* and *S. cernua*, both very easily naturalized, as the roots can be dug with a little soil attached. *Aplectrum hyemale*, found but rarely, is easy of culture and transplanting, owing to its having bulbs like many exotic species. The bare flower-scape arises in early summer, and afterward a single broad evergreen leaf appears to mark the place. *Liparis liliifolia* also has fleshy bulbs above the ground, is easy of cultivation and when the purplish lipped flowers are open, a little colony is very pretty and interesting.

The cypripediums are the best known and most sought of native orchids, *C. spectabile* is becoming rare and more difficult to get, but there are plenty of places in the remote North woods where it is still found in quantity. This plant is usually regarded as a bog habitant, but it occurs also on the slopes of shady ravines. *C. pubescens* is found in the same situations, and *C. parviflorum*, the smaller yellow species, is a bog-plant. All these are easy of cultivation if moisture is secure. They are found at times where it seems to be very dry at the roots, but an examination proves that there is seepage from above that provides the necessary moisture, and gives a clue to their culture. In the ravines on the shady slopes, cypripediums reproduce themselves from seeds to a greater extent than is supposed under cultivation, and the pretty yellow and pink flowers are much admired and sought. *C. parviflorum* is exceedingly fragrant when in bloom. *C. acaule*, the common red-and-brown species, is not so tractable, but on sloping banks in partial shade they have flowered for two years and seem to be established. Two other species, *C. arietinum* and *C. candidum*, are hard to obtain, and more difficult to grow than the others, but with care and study of their natural conditions, it is probable that success may be attained with them. There are several Pacific coast cypripediums that have not proved tractable. Possibly they are hardy in the East under proper conditions; this is the case with *Epipactis Royleana*, and *C. californicum* and *C. montanum* are valued in gardens abroad. There are also some fine new species from China and Thibet that give promise and have flowered in Massachusetts gardens from roots brought home by Wilson. We may yet see these widely distributed. There seems to be no recorded example of hybridization among our native cypripedes; it has been attempted many times, and it is strange, in the light of the numberless crosses made among the exotic species, that ours remain true even to themselves, and cannot be mixed.

There are many small gardens in which the study and culture of hardy orchids might well be taken up, together with that of the ferns. The same conditions might be made ideal for both in a very limited area. It is essentially an occupation for the amateur, for the idiosyncrasies of the plants are many. One must have the liking for exploration of the woods and bogs where the plants grow, and preferably gather the roots oneself. In no other way can the special requirements of each species or even each individual be studied and met.

E. O. Orpet.

The culture of epiphytal orchids in Florida.

The greatest trouble in the cultivation of epiphytal orchids on trees in southern Florida is in getting them completely established in their positions on the branches or trunks. In a natural state, the seeds of orchids, which are exceedingly fine, are carried largely by the wind and scattered over the trunks and branches. Those that alight in suitable places germinate and send their roots over the surface of the bark and in time become flowering plants. In artificial culture the plants already grown are placed on the trees, and unless this is done right and they have proper care for awhile, until they become established, but few will live and do well. Indigenous orchids are very abundant on the trees in the hammocks of south Florida, both species and individuals, there being known at present not less than twenty native species in this region. One of these, *Epidendrum conopseum*, ranges throughout the northern half of the state and into South Carolina, Georgia, and Alabama. Another species, *E. tampense*, is distributed over most of the peninsula, and these are endemic. The others are confined to the lower part of the state and are found in the American tropics.

Strong, healthy plants should be chosen and the potting material cleaned out from the roots as much as possible. The roots should be spread out, and a little sphagnum placed over them; then drive a small nail through a strip of mosquito-wire netting and into a tree where it is desired to place the orchid. Then place the roots of the plant against the tree close to the nail, adjust the strip tightly over them and nail through it into the tree on the other side. It may be best to put a second strip across, as it is absolutely necessary that the plant be firmly fastened, for if it is at all loose it never will do well. It should be watered at the time of planting and at intervals of a day or two, if the weather is dry, until it is established.

Orchids should be put on trees that have firm bark which does not scale off. Live oaks are ideal trees and red bay (*Persea carolinensis*) is good. They may be placed on smooth-barked trees but the rough-barked are preferable. Wild rats are often abundant and when orchids are placed on sloping or horizontal surfaces they destroy the plants; therefore, fasten the plants to vertical stems. They may be grown in high or low hammock or on cultivated trees; in fact, in any location where the air is not too dry or the plants are not too much exposed. They may be kept in pots of leaf-mold under a slat-house.

Sometimes orchids are attacked by what is apparently a fungous disease, which operates suddenly and fatally. The sheaths, pseudobubs or leaves at first become almost semi-transparent, looking as if they had been frozen; then they turn brown and the plants die. So far, dendrobiums have not been attacked but cattleyas and the thick-leaved oncidiums have suffered greatly. If noticed before the disease has progressed far, the sheaths of the leaves should be stripped off, the plant sprinkled with water and well dusted with sulfur, and if this is washed off by rain, applied again.

The coolhouse orchids have totally failed after repeated trials. But most of the cattleyas, the dendrobiums, oncidiums, epidendrums, lycastes, maxillarias, brassias and brassivolas, gongora, lælia, miltonia, vanda, cyrtopodium and others have succeeded excellently. *Phalænopsis amabilis* and *P. Schilleriana* are succeeding excellently on trees in low hammock and bloom beautifully every winter. With cypripediums, cymbidiums, phaius and some other terrestrial orchids in the hammock, the success has been only moderate.

Epidendrum tampense is an attractive native orchid and well worthy of cultivation; *E. nocturnum* and *E. cucullatum* are interesting; *Cyrtopodium punctatum* forms great masses on the trees and sometimes a single plant may bear 300 or more flowers. These are of considerable size and, with the scapes, are yellowish green variegated with red brown, a most striking and beautiful plant. *Oncidium luridum* and its var. *guttatum* are very fine, having immense heavy leaves and long branching spikes of brown-red and yellow flowers. These spikes or panicles curve gracefully and are sometimes 10 feet long. *Oncidium sphacelatum* is an epiphytal orchid that has become terrestrial or subepiphytic in its habit, growing wild on decaying logs, the bases of trees, or even in the soil of pine woods. It has tall panicles of bright yellow and brown-green flowers. The last seven species are natives of Florida, and all of them are doing well in cultivation.

There is apparently no reason why anyone may not have a few of these strange and beautiful plants anywhere in Florida. In the northern half of the state, the hardy Florida species and others of similar character from northern Mexico, Japan, north India or the cooler parts of South America can be successfully cultivated, while in the warmer part of the state a large proportion of the tropical species can be grown. They do well on trees in hammocks, in artificial groves and even on isolated trees where they are not too much exposed. Nothing is more entrancing than the cultivation of these strange, often weirdly beautiful forms. If one once becomes interested in orchids he is sure to be a confirmed lover of them ever afterward.

Chas. T. Simpson.

Cultivation of the various kinds of orchids.

At this point are brought together, in alphabetic order, the leading orchid genera for instruction as to methods of cultivation. The list is prefaced with remarks on orchids in general and their cultivation, even though they cover some of the ground already gone over in the article by Robert M. Grey, which was contributed to the Cyclopedia of American Horticulture. The orchids are so special in their requirements that another experience will be valuable.

Orchid-culture has ever been that of the few who are students of plant life and who can give time and care to their plants. This statement has been exemplified by many professional men who have used this means as an alternative to their other cares, and find it all-sufficing since so many species require special treatment and some are never understood. If evidence were needed, it is proved by the fact that so many fine collections are dispersed after the decease of their owners, and that decadence is the usual result with plants that thrived well before passing into other hands. There was also the added interest that when buying imported plants, the flowering of many rare and valuable kinds resulted, which at times paid a liberal interest on the original investment. It is safe to assume now that we shall secure relatively few more new species of value from the native wilds, these having been searched to such an extent that few are the expeditions now made up in search of them.

The greatest impetus in orchid-cultivation today is in the raising of plants by crossing and hybridization under conditions of cultivation, and the time is with us when we do not need to import either new species or plants of well-known forms. It is worthy of remark that the variation among orchids as we know them is such that no two plants are alike in the coloring or marking of the flowers. In the well-known *Cattleya Trianæ*, or any other of the forms of the *C. labiata* group, each plant is different. Doubtless this is due to the fact that most orchids require insect agency for pollination. Usually each flower has a highly colored lip or labellum, to attract the insect, with radiating lines or tracks leading to the nectar and, when this is secured, it is impossible for the agent to withdraw from the flower without taking toll in the shape of pollen which, of necessity, is deposited on the next individual visited. In some orchids there are distinct keels on the lip, the track thus being emphasized and the bee compelled to take the narrow path that his mission shall be fulfilled.

It is often said that orchids need a well-marked period of rest. This is not always possible with specimens newly received from the wilds, as the flowering period has to be changed to accord with our winter or summer which in time governs their well-being. We will assume that the flowers have been pollinated by insect agency, and the seeds have matured. This maturation usually requires about a year. No one knows the number of seeds that will be contained in a healthy capsule. There must be tens of thousands, a very small proportion of which ever reach maturity when sown under glass; but here is apparently a reason for the time taken to ripen the capsule, that it may take place about the period for the plants to bloom again, which is presumably the most favorable or rainy season, and the seeds are distributed by the breeze to suitable media, and a proportion germinates and grows. We learn by sowing under glass that very few, even under the most careful treatment, ever live through the vicissitudes of initial stages, the tiny green globes or thalli having no true roots for months. It is perhaps a year after sowing the seeds before true roots are visible, but in the meantime, a hot drying day, if no gentle spraying of moisture is given, will blast all the hopes of many months' waiting; but we have the compensation of knowing that each plant we raise will be eminently fitted to survive under greenhouse conditions. The recent careful laboratory investigations have suggested rational methods of procedure in the growing of seedlings, and the subject will probably gradually pass out of the region of accident and doubt. (See page 2387.)

Variation that obtains among wild orchids is also present in various degrees among crosses and hybrids raised under cultivation. This was proved by the raising of over eighty plants of *Cattleya Thayeriana*, no two of which were alike, and some could not have been attributed to the same origin were it not for the connecting-links that rounded out the series.

In Europe, a great liking is shown for the coolhouse odontoglossums, especially since the raising of plants from seed has proved or illustrated the origin of many supposed species, the type flowers of which were sealed up for twenty-five years in Vienna in the herbarium of the late Professor Reichenbach who, in his day, was the dean of the orchid botanists, and whose collection was but this year uncovered. Following is a clause in Reichenbach's will: "My herbarium and my botanical library, my instruments, collection of seeds, etc., accrue to the Imperial Hof Museum in Vienna, under the condition that the preserved orchids and drawings of orchids shall not be exhibited before twenty-five years from the date of my death have elapsed. Until this time my collection shall be preserved in sealed cases. In the event of the Vienna Institution declining to observe these conditions, the collection falls under the same conditions to the Botanical Garden at Upsala.

Should the last-mentioned institution decline the legacy, then to the Grayean Herbarium in Harvard University, Cambridge, Mass. If declined by that institution, then to the Jardin des Plantes, at Paris, but always under the same conditions, viz., of being sealed up for twenty-five years, in order that the inevitable destruction of the costly collection, resulting from the present craze for orchids, may be avoided." See Bailey, "Annals of Horticulture," 1889, with portrait, of Reichenbach, from "Gardeners' Chronicle." In the meantime, after the first lamentations, and the gathering of the available living types, cultivators began work with such authentic material as they had until now we have plants with three to four genera in their parentage, and the end is not yet. It will readily be understood that the recording and taking care of the nomenclature of these results as they occur week by week, is no simple matter, but it is being undertaken in such a way that for the present we know the origin of the many plants that have been raised. There is no other record in plant hybridization to compare with that of the orchids. In most cases, drawings have been made of the originals for filing in the archives. The Mendelian theory will surely find much material in the work of the orchid-cultivators, because of their painstaking in the matter of pedigree. It was early decreed that a plant without a pedigree could not be considered for recognition with a name. This seemed hard at times, because of special merit, but the cultivator had to be content with the result rather than with the honor. It is a curious circumstance that in the raising of orchids from seeds, many appear where they were not sown and in the most unexpected places. These are later placeable where they belong if there are other forms with which to connect them, but failing this there is no admitted reason for giving a name.

In past years, large prices were paid for forms of orchids that were unique, as for albinos, specially marked, or highly colored variations, all being imported forms. It was thought that these could be reproduced from seeds; this has not been true in most cases, even albinos having reverted to the normal and in most cases very poor forms. It is now a recognized principle that none but the very best varieties should be used as parents, and from these there are always a number of degenerates.

Orchid-hybridization is not prosecuted in America to the extent that it was at one time. It requires years to secure results that are obtained at far less cost in Europe, where the plants are more easily obtainable. We may mention a case in which nineteen years was required to flower a plant, the only one that survived from a certain cross, and when it bloomed it was of no value although true to its parents, one of which was of poor constitution.

General cultural requirements.

Most tropical orchids of cultivation are epiphytal, very few growing on the soil, and the requisite conditions are largely a matter of atmosphere,—not necessarily temperature. Heat is necessary, but only to be taken seriously in winter when it is generated artificially, sometimes from superheated pipes, which is always detrimental to the well-being of the plants. It is better to have a number of pipes heated to a moderate degree. In summer the heat is not a factor except with the cool Andean plants like the odontoglossums. If plenty of ventilation is given from the time frosts cease at night, one cannot imitate easily the night atmosphere outdoors, and the more the plants get of it when genial, the better they thrive.

Another factor under glass is shade from the sun. This must be governed by the amount of direct light admitted. It must be understood that a house running north and south will not get so much heat from the sun's rays as one built east and west. In a house having full exposure to the sun in winter, orchids will need shading to some extent most of the winter, while one running north and south will not have to be shaded from the month of October until March. The plants are injured by the loss of green in the foliage due to exposure. Part of this will return when shade is given, but some of the older leaves will turn yellow and drop off. It is the medium course that conserves vitality, while ripening the growths perfectly, that the cultivator needs to bring about. The successful grower gives intensive study to each individual plant. We have had the experience of miltonias that thrived perfectly at the end partition of one structure, but never prospered when they were removed to other similar conditions. It was a question of exposure. So it is that cultivators often place a plant in a particular position in a house, seemingly the purest empiricism, but a practice not to be despised by those who want to succeed. It is not surprising that plants collected from the odd corners of the tropics, placed together in a small house where the temperature is to be maintained largely by artificial heat, require careful and individual study. With many difficult orchids, one cannot imitate the atmosphere of the Andes when the dog-days come, or when zero temperatures obtain outdoors and the wholesome atmosphere disappears by the exhaustion from superheated pipes.

Orchid-culture in America will be largely confined to a few genera, the "cool" kinds will rarely succeed, but those from Mexico to Brazil and most of the East Indian and Philippine kinds can be made to thrive better here than in Europe.

A number of American terrestrial orchids are amenable to cultivation. Cypripediums lend themselves kindly; and most of the others, as the calopogons, spiranthes, pogonias and habenarias, are plants essentially of the swamps or woods where moisture is secure all summer, but are not easily tamed in the usual way as are other plants, and yet their essential conditions may be met by the careful and thoughtful gardener.

The main cultural groups.

The orchid family is usually classified by growers into at least three divisions, for providing suitable temperatures and other conditions, especially atmospheric, although a closer analysis would make at least four cultural groups.

1. The warmest division should be kept at a minimum of 65° in winter, to take care of the vandas, aërides, saccolabiums, phalænopsis, angræcum, anœctochilus, habenaria, a few of the strictly tropical dendrobes and other less known genera. Most of these may be termed extra- (or supra-) epiphytal for the reason that they secure most of their needed moisture through their large aërial roots, the material that they are planted in being secondary in importance as a source of nourishment. There are many cypripedes that need this warm treatment, such as the Malayan, Bornean and some of the East Indian species, for they speedily resent being chilled. The higher temperature makes the cultural details in winter more difficult to regulate since moisture must be kept up to counteract the dry heat from the pipes; therefore it is always best to have a number of pipes moderately warm rather than a few superheated. Insect pests are also more persistent under superheated conditions. Thrips and red-spider are harder to fight, and must be kept down by frequent light sprayings with approved insecticides containing nicotine, applied with an atomizer once a week in case of an invasion. Troughs on the heating-pipes for the evaporation of water are essential, and sometimes, in large structures, open tanks are used under the stages on which the plants stand filled with water which is heated by coils. Too much emphasis cannot be placed on the keeping of a proper atmosphere as well as heat for these tropical plants. This can be brought about

by proper ventilation and shading from the hot sun, to prevent the escape of the atmosphere when it has been secured. Most of the foregoing orchids are natives of the tropical jungles where shade is ever present, and exposure suddenly after a few dull weeks to the hot rays of the sun under glass in early spring will do harm.

2. The temperate division is the home of by far the largest number of the cultivated orchids. A night heat of 50° in winter as a minimum on extreme cold nights will be better for the plants than a higher temperature. It is well known that, after a period of severe cold, many of the older leaves of cattleyas turn yellow and fall off, a sign of the stress to which they have been subjected. In moderate weather, 55° will be better, especially if plants are in bloom. In addition to the cattleyas, the lælias, cymbidiums, sobralias, oncidiums, stanhopeas, epidendrums, brassias, miltonias, catasetum, phaius, the Mexican odontoglots, and East Indian dendrobes, and many cypripedes, will thrive best in the temperate house. If but one house or division is to be devoted to orchids, this should be an intermediate one for the reason that, with the exception of the purely tropical species and the coolest Andean, the greatest number can be cultivated therein by the careful utilization of the various parts of the house for individuals that need the warmer or cooler end or a little more shade, conditions that are soon discovered by the observant cultivator. The admission of fresh air when weather permits is of the utmost importance. In summer the house should have free air day and night from the first of May until late September. It is the greatest factor in building up the plants after the exhaustion of flowering. At this time, watering should always be performed in the late afternoon; and if watering is not necessary, spray the plants overhead after each very hot day. In winter, water is best given in the morning that the surplus will dry off before night.

3. A coolhouse is necessary for the Andean odontoglots, cochliodas and their now numerous hybrids, the sophronitis, disas, masdevallias, *Cœlogyne cristata*, *Epidendrum vitellinum*, lycastes, and a few other plants. These are among the most charming of all orchids, the odontoglots especially. Difficult as the odontoglots are to manage, much success has been attained by care and suitable structures, preferably with a north slope with the shade of some other building to the south. Roller shades on the coolhouse should be kept about 12 inches above the glass roof to admit of a free circulation of air beneath in hot weather, with ventilators at the top and bottom near the pipes. Cool orchids require to be kept moist all the time. There is no very marked period of rest, as they are subject to heavy night dews where they grow; but in the dull winter months, all the sunlight must be admitted, as most of the active growth is made in winter and early spring. These plants are a real test of the skill of the grower. A few cool summers build up the plants so they flower well and it has been noticed that the best results are obtained in the cooler parts of the country, or near the seashore.

Further suggestions; propagation.

Many genera in cultivation are seldom seen in collections here, but a knowledge of their native habitat, and especially the elevations at which they grow, must be the clue to their needs in cultivation, together with a study of their root-system. The roots that are white, are aërial, and those that have root-hairs are terrestrial, and being of the earth will best be treated as pot-plants.

Many species are easy of propagation by division, and it is often advisable to divide plants rather than grow them on into large specimens. The plants should be kept in reasonable size. Propagation by means of seeds is a slow process, and in many cases one cannot be sure what will come true from seed. Even from well-marked types there is always the possibility of reversion. Especially is this the case with albino forms, so many of which occur among imported specimens.

Cultivation of leading genera of orchids.

Acanthophippium. For culture, see Acanthophippium.

Acineta. For culture, see Acineta.

Ada. A small genus of few species with bright orange-colored flowers that add color to the coolhouse among the odontoglots, and require similar treatment.

Aërides. True epiphytes that revel in a moist atmosphere in a warmhouse with a winter minimum of 65°. Very little potting material is desirable, just enough to anchor the plants in the pots. The roots made from the stems as the plants grow seem to gather the needed nourishment, and care must be taken not to injure these or check them, as they are very active, even in winter. Some of the species are very fragrant, all are beautiful and last a long time in bloom. A surfacing of moss should be added to a thin layer of osmundine, and the drainage made up of large pieces of charcoal and crocks. Basket-culture is often adopted, but it is hard to re-basket without injuring the roots, but the old material may be removed, the roots washed and new added each year until new baskets are necessary by reason of decay.

Aganisia. Warmhouse plants, needing little material about the roots, and to be suspended near the roof glass with a maximum of light but no direct sun in summer.

Angræcum. Culture as for Aërides.

Anguloa. Culture as for Lycaste.

Anæctochilus. Terrestrial tropical orchids with creeping root-stems, foliage beautifully marked, the Malaccan name being "written flower" owing to the marking resembling hieroglyphs, done in many colors. These plants are best grown in the warmest part of the structure, in a small frame or under bell-glasses to keep the leaves unspotted and ensure uniform heat and moisture, but some air must be given to guard against condensed moisture and consequent drip. Difficult to import and not often seen in collections.

Ansellia. A tropical African genus of a few species growing on trees, where there is a climate of abundant moisture during the growing period, with a dry season of about half the year. Culture in the warmhouse, witholding water to ripen the growths well after they are completed.

Arachnanthe. Culture as for Aërides.

Arpophyllum. A temperate house genus seldom seen in cultivation, coming from high altitudes in Mexico and Guatemala, best grown in baskets, in shade and plenty of moisture. Culture same as for Lycaste.

Aspasia. Once considered as odontoglossums. There are about eight known species, seldom cultivated, requiring treatment as for odontoglots.

Batemannia. Plants that are never at rest, needing a moist tropical atmosphere, with no appreciable resting as water is needed all the time. Very little material is needed at the roots, and this kept in a sweet healthy condition by adding new material and the removal of old portions. Red-spider must be kept away by frequent washing of the foliage.

Bifrenaria. Brazilian plants requiring treatment same as cattleyas from that region, and a trifle warmer position than for those from Colombia.

Bletia and *Bletilla.* Cool terrestrial plants, but not hardy. Can be grown in an ordinary greenhouse and kept dry in winter when at rest, repotting in fresh material when growth begins in spring.

Bollea. Culture as for Batemannia.

Brassavola. Best known by reason of *B. Digbyana*, which is so much used by the hybridist to put the fringed lip on cattleyas and lælias, with which it can be combined readily. Of culture the same as for cattleyas, slow to increase by division, but otherwise easy of culture.

Brassia. These are seldom seen in modern collections, but were old-time favorites, growing and flowering freely in an ordinary structure with no special care, and may well be associated with the warm oncidiums as to potting and subsequent routine.

Broughtonia. The only species known in cultivation here, *B. sanguinea*, is hard to cultivate for any long period. It is best attempted on a portion of osmunda rhizome, with a little moss at the roots, hung near the glass in the warmhouse.

Bulbophyllum. Among these are the giants among orchids. Some species attain huge size, require tropical treatment in a steaming atmosphere during growth and the flowers when produced are remarkable, though very seldom seen except in botanic gardens. Some species are small and require to be grown on blocks of wood; increased by division.

Calanthe. Deciduous bulbs that need rest after the flowers are cut in midwinter, until there are signs of growth in spring, then shaken out to be potted in turfy loam, a little well-decayed manure, in pots or pans with good drainage. The warmest position or shelf with shade will best suit calanthes. It might be said they will enjoy a little fire heat every day in the year, with proper shade and plenty of moisture. The long flower-scapes begin to develop in late summer, and when these appear liquid nourishment must be given frequently to grow large bulbs. The flower-scapes are long, last a long time in perfection when cut, and as the flowers open, cooler and drier treatment may be given. Increase is readily made by means of the old bulbs that will often grow again, and these often double in number each year. A valuable florists' orchid when its culture is understood, and profitable to grow.

Calopogon. For culture, see Calopogon.

Camarotis. Culture as for Aërides and Vanda.

Catasetum. Curious and beautiful orchids from Central America, that often have the two sexes in different individual plants, a fact that was long a puzzle to botanists, and the peculiar structure of the flowers makes the plants very interesting. The culture is not easy in gardens; plants usually dwindle after a few years, but plenty of heat and light when in growth, with a long resting-period between, is necessary, and growth is best when the plants are suspended from the roof.

Cattleya. The most popular and best known of the orchids grown for cut-flowers, with few exceptions. Best grown in the intermediate house. For culture, see Cattleya.

Chysis. Culture as for Vanda.

Cirrhopetalum. For culture, see Cirrhopetalum.

Cleisostoma. Culture as for Aërides.

Cochlioda. A genus much prized by hybridizers of late for the color it imparts to the odontoglossums, the hybrids of which are now known as Odontioda and form a pretty rose-colored series of cool orchids, very popular where they thrive. Treatment same as for odontoglossums.

Cœlia. Culture as for Epidendrum.

Cœlogyne. Terrestrial orchids, both temperate, as *C. cristata*, and tropical, as *C. Massangeana* and *C. pandurata*. Species like the last two need basket culture suspended, as their flower-spikes are dependent. The well-known *C. cristata* will do well in a coolhouse when at rest before flowering, soil containing a portion of earth, and liquid manure during growth is necessary to produce strong flowering growth, increased by division directly after flowering period.

Colax. Culture as for Lycaste and Zygopetalum, in an intermediate house.

Comparettia. Culture as for Broughtonia, but in an intermediate house.

Coryanthes. Culture as for Stanhopea.

Cycnoches. Curious Central American plants, often called the "swan's-neck orchid," requiring treatment identical with that of dendrobium, and well-marked resting-period after growth is completed.

Cymbidium. Decorative evergreen tall-growing plants that have many flowers of long duration. All are from the East Indies, but do well in an intermediate and even a cool house in winter. They also do well when planted out among rockwork in large structures, and the hybridist has added very many fine plants that go to make up the collection in gardens. A soil with loam added and manure-water added frequently when the plants are growing or rootbound will induce strong growth. The plants are impatient of disturbance at the roots, but if carefully done they may be increased by division. Seeds germinate freely. For further cultivation see Cymbidium.

Cynorchis. Terrestrial plants from Madagascar and Natal. Culture same as for Bletia, repotting in fresh material in spring.

Cyperorchis. Culture as for Cymbidium, to which genus they are sometimes referred botanically.

Cypripedium. Terrestrial orchids, although sometimes growing on rocks with little humus about the roots, including tropical or warmhouse plants (now referred to Paphiopedilum), these being often with mottled foliage; intermediate house plants as *Paphiopedilum insigne* and its many hybrids, and the hardy species, always deciduous and widely distributed. Cypripediums are herbaceous, having no pseudobulbs, and should never lack for moisture or be overpotted. Propagation by division or seeds, which germinate freely. Albino forms have been reproduced by seeds, to a large degree true to the parent plant; also specially fine varieties.

Cyrtopodium. Culture same as for Cycnoches, repotting in spring; carefully shade the young foliage until mature. Flowers are produced with the commencement of young growth in spring. Avoid spraying over young growths, as water lodging often induces decay unless the house is well ventilated and the day bright.

Dendrobium. For culture, see Dendrobium.

Diacrium. Culture as for Epidendrum and Cattleya.

Disa grandiflora. An orchid from Table Mountain, is now protected by the state, owing to its scarcity due to collectors, is a very beautiful plant when in bloom, but it is doubtful whether it has ever been cultivated here with success, though not difficult to handle in European gardens, where it is easily raised from seeds and by division. It is strictly terrestrial, but seems unable to bear heat. There are several other species and many hybrids from these, but none seems amenable here.

Epidendrum. A genus of very much varied plants, some being stem-rooting and without bulbs, and these require all the sun to flower freely; others have pseudobulbs, are easy of culture and do well in the intermediate house, with treatment same as for cattleya. For further culture, see Epidendrum.

Eriopsis. Culture as for Lycaste, in shallow baskets suspended in an intermediate or cattleya house. Repot when growth commences, with great care, as the plants are impatient of root-disturbance. *E. rutidobulbon* is the best known species, but it is very rare even in its native Antioquia.

Eulophia. Culture as for Calanthe.

Galeandra. Culture as for Calanthe.

Gomesa. Culture same as for Broughtonia. A Brazilian genus, species of which are rarely seen in cultivation, being largely of interest in a botanical way.

Gongora. Requires to be grown in baskets suspended, as the flower-spikes are produced from the base of the plant downward. No obstruction by way of drainage should be allowed to hinder these. An intermediate treatment, with less water when resting will suit the plants. They are seldom seen, as the flowers have no bright coloring to attract, though some are very fragrant.

Grammangis. For culture, see Grammangis.

Grammatophyllum. For culture, see Grammatophyllum.

Habenaria. Both tropical and temperate species are included. The plants are always deciduous and the warm species need resting until new growth commences, then careful repotting in new material. A warm shady corner suits their needs best. The hardy species are found in both the Old World and New, growing in moist rich soil with partial shade, but sometimes in full sun in marshy land.

Hæmaria. For culture, see Hæmaria.

Hartwegia. Rarely seen. Culture as for Gomesa.

Houlettia. Culture same as for Stanhopea, in intermediate house, kept rather dry in winter, using baskets.

Huntleya. Culture as for Batemannia.

Ionopsis. For culture, see Ionopsis.

Isotria. Culture as for Pogonia.

Lacæna. For culture, see Lacæna.

Lælia. For culture, see Lælia.

Læliocattleya. For culture, see Cattleya and Lælia.

Leptotes. Culture as for Lælia.

Limatodes. For culture, see Limatodes.

Liparis. For culture, see Liparis.

Lissochilus. A tropical African group, requiring soil similar to phaius, made up of part good loam, with a little old manure, sand, and plenty of drainage. In Africa the plants are sub-aquatic, and have been cultivated with water-lilies. This is not generally practised, however. The flower-spikes sometimes attain 12 feet in height in *L. giganteus*. The warmest house is necessary, with frequent applications of liquid manure during growth with somewhat drier treatment in winter until new growth begins. Shade in summer is necessary as the foliage is thin when new.

Listrostachys. Culture same as for Angræcum or Phalænopsis, in very shallow pans as the plants are small.

Luisia. For culture, see Luisia.

Lycaste. Semi-terrestrial orchids requiring intermediate treatment with shade from direct sunlight at all times as the foliage is thin and easily injured. *L. Skinneri* is often grown in baskets suspended, but should be kept moist at all times as flowers are produced at various seasons, and growth is often being made during the whole year. A portion of loam in the soil, or the heavier grade of osmundine is best suited to the roots of orchids of this nature. Propagation by division.

Macodes. Culture as for Anœctochilus.

Masdevallia. Of all Andean orchids these do the best in an ordinary coolhouse when shaded from sun, and watered frequently, for, having no pseudobulbs, there is no reservoir to draw upon. The colors of most masdevallias are wonderful, and the plants easy of culture in the usual orchid material. Increase is readily made by division of the stems just after flowering, being careful to save the roots intact. For further cultivation, see Masdevallia.

Maxillaria. Once a very well-known genus of free-flowering orchids of easy culture, some species being fragrant, but of late, owing to the small flowers and dull coloring, the plants have disappeared from collections with the possible exception of *M. Sanderiana*, which is an exception as to coloring, it being attractive and the flowers large. Treatment as for Lycaste, and propagation by division.

Mesospinidium. Culture as for Cochlioda, to which it is closely allied.

Microstylis. For culture, see Microstylis.

Miltonia. These were long known as odontoglossums, and *M. vexillaria* is one of the prized orchids today. It is a little particular as to position in the house, needing plenty of sun during the winter, which is the period of growth. After flowering, in May or June, there is a short time of rest, when the plants are much weakened and need careful nursing with shade to enable them to recuperate and make strong growth again. *M. Roezlii* is very similar, but is a warmhouse plant requiring 10° more heat, and flowers in winter. These are the two best known species, but, with the exception of *M. Roezlii*, all need the intermediate house. Propagation is by division when growth is starting, at potting time.

Mormodes. For culture, see Mormodes.

Mysticidium. Culture as for Angræcum.

Odontoglossum. A very popular genus in Europe, but difficult to grow well here owing to the extremes of temperature. Natives of the Andes, where the temperature does not vary 10° winter or summer. Some success has been attained here, especially during cool summers. For culture, see Odontoglossum.

Oncidium. There are a large number of species, ranging from the alpine Andean small-growing ones to large tropical plants. No genus of orchids presents such wide variation and study. Their culture is easy when the needs of the individuals are studied, and these are governed by the elevation at which the plants are found growing and imitating as well as can be the temperatures. Some of the cool species need moisture all the time, while the Mexican and Central American ones do best with a defined period of rest, meaning less moisture and heat, generally in the winter, sometimes before flowering and often after. The intermediate house will suit all except the cool ones. The flower-spikes are often very long, as in *O. macranthum*, and need careful training to keep away from the glass. *O. Rogersii* is perhaps the best known and is a popular florists' winter-flowering orchid imported annually in quantity. The usual potting material is suitable, but oncidiums seem to do best when restricted as to root-room.

Ophrys. Culture as for Habenaria.

Palumbina. Closely allied to oncidium, and sometimes included. Culture as for the intermediate house oncidiums.

Paphinia. For culture, see Paphinia.

Paphiopedalum. For culture, see Paphiopedalum and Cypripedium.

Peristeria. A tropical orchid requiring much the same treatment as calanthe when growing, but the peristeria does not need such a marked period of rest, as it is evergreen. It is terrestrial, requiring a loam mixed with old manure, and liberial supplies of moisture. If black-spot disease appears, it must be cut out at once and the cavity filled with lime and sulfur. This disease seems to be common. The tall spikes of sweet-scented flowers, the center of which resembles a dove, are much admired and last long in perfection.

Pescatoria. Culture as for Zygopetalum.

Phaius. Eastern tropical plants of great beauty, one of which has become naturalized in the West Indies. Terrestrial in habit, needing a soil composed largely of loam rich with humus, and liberal feeding when in full growth. Propagated by division, after flowering.

Phalænopsis. Tropical epiphytes needing the warmest temperature admitted in orchid-culture, which is a minimum of 65° in winter and this in the coldest weather, and an atmosphere never allowed to become arid or stagnant. At some seasons drip from above easily proves fatal. Very little material is needed at the roots, as they love to escape the receptacles when doing well and hang pendent. Osmundine is the most suitable material to use as it is lasting, but where sphagnum will live and keep green it is well to use it as an index to the need of moisture. Many growers never spray phalænopsis overhead, water in the center of the plants often causing decay, but in very hot weather this will evaporate by the addition of air. Having no pseudobulbs, but a pair or more of large leaves to support, the plants must never lack moisture. The flowering period is mostly in winter or early spring and the beautiful sprays of bloom are now a large item among growers for market since the plants can be so readily obtained from the Philippines. There is a tradition that phalænopsis do best near the coast. Certain it is, that California growers are having great success with them.

Pholidota. For culture, see Pholidota.

Phragmipedilum. For culture, see Phragmipedilum.

Physurus. From Colombia, but with foliage similar to the anœctochilus from the Malay Archipelago. Physurus grows at an elevation of 5,000 to 6,000 feet and will thus be best treated in the same house with the odontoglots. One species occurs in Peru.

Platyclinis. Warmhouse plants, all of which have fragrant flowers, and are easy of culture. The best known is *P. glumacea*, but *P. filiformis* is sometimes seen. Easily grown in osmundine and propagated by division.

Pleione. A pretty genus of East Indian plants known there as the crocus. Flowers mostly pink, and produced after the foliage has died down. Best grown in shallow soil in pans, with treatment as for calanthe.

Pleurothallis. Small-growing plants of great interest botanically but many have flowers that require the aid of a microscope to see their beauty. Best grown in the cattleya house in shallow pans suspended near the glass. They need moisture at all times but very little material at the roots. In summer the plants may be placed with the masdevallias, at the warm end of the odontoglossum house.

Pogonia. Hardy orchids found in wet soil with very showy flowers, but difficult to transplant unless plenty of earth is taken with the roots.

Polystachya. A tropical African genus, rare in cultivation.

Promenæa. Culture as for Zygopetalum.

Renanthera. Culture as for Vanilla.

Restrepia. For culture, see Restrepia.

Rhynchostylis. Culture as for Saccolabium.

Rodriguezia. For culture, see Rodriguezia.

Saccolabium. Culture as for Aërides. See also under Saccolabium.

Sarcanthus. For culture, see Sarcanthus.

Sarcopodium. A genus separated from Dendrobium and Bulbophyllum, and requiring treatment similar to that of Dendrobium.

Scaphosepalum. For culture, see Scaphosepalum.

Schomburgkia. Culture same as cattleya, but requires to be well ripened by exposure to more sun, especially in winter, to induce flowering. The plants are seldom seen, as they are large, and the flowers inconspicuous by comparison with other orchids, borne on stems sometimes several feet long.

Scuticaria. For culture, see Scuticaria.

Serapias. For culture, see Serapias.

Sobralia. A group of reed-like plants, flowering at the end of new shoots, several large cattleya-like flowers coming in succession, but, these being short-lived, are of no value commercially, but are interesting plants in a collection. Specimens may be grown to a large size and the plants do not deteriorate. Many hybrids have been raised, but are seldom seen in gardens. Propagation by division usually, and a soil as named for cœlogyne.

Sophronitis. A brilliant-colored little orchid, an alpine plant. Easy of culture in shallow pans suspended near the roof. *S. grandiflora* is the best known, and has been much prized for imparting its color to the larger cattleyas and lælias. At least one hybrid has been raised here, and many more in Europe and Britain. The color is usually equally brilliant in secondary crosses. Does best in the cattleya house and should never become dry at the roots or the plants will suffer.

Spathoglottis. For culture, see Spathoglottis.

Spiranthes. Hardy native orchids popularly known as "ladies' tresses." Easily transplanted, but seem to flower biennially, late in summer and early autumn.

Stanhopea. Treatment similar to gongora with similar pendent flower-spikes through the bottom of basket. Flowers very striking in color and odor, but do not last long.

Stenorynchus. Tropical plants allied to spiranthes, with variegated leaves and colored flower-stems. Treatment same as for Paphiopedilum.

Thunia. Tall-growing bamboo-like stems with clusters of flowers at the top. Very attractive but not often seen owing to the attacks of red-spider on the thin foliage. After flowering, the plants need resting, being kept dry but in a warm house, until growth starts again. Propagation is by cutting the stems in pieces with several joints, laying on damp moss in a propagating-case in strong heat until roots are visible, then potting and treatment as with older plants. Loam should be added and weak liquid manure-water when rapid growth is produced.

Trichocentrum. For culture, see Trichocentrum.

Trichosma. Only one species seems to be in cultivation, *T. suavis*, a very pretty fragrant-flowered orchid, needing intermediate house treatment, with culture same as for cypripediums, repotting to be done in winter after flowering season has past.

Tricopilia. Beautiful and fragrant orchids, free-flowering, needing same culture as lycaste.

Vanda. Culture as for Aërides. See also under Vanda.

Vandopsis. Culture as for Vanda.

Vanilla. Tropical epiphytes producing a valuable bean-like capsule and the only orchids known that have a commercial value apart from the flowers. They are true epiphytes, requiring support such as a wall at the end of an orchid house where moisture is assured for the creeping roots. Pollination must be done by hand to be sure of pods being formed. The culture of vanilla is carried on on a large scale in the tropics, but it is impracticable under glass. Easily propagated by cutting up the rooted stems into pieces.

Warrea. Culture as for Phaius.

Warscewiczella. Culture as for Zygopetalum.

Zygopetalum. Very decorative winter-flowering plants, *Z. Mackayi* being of easy culture, and perhaps the only species well known. It is very free-flowering, fragrant, will seed freely and produce plants true even though hybridized by other pollen, even unto the fourth generation. It is one of the oldest known orchids, requiring soil similar to phaius and an intermediate treatment.

E. O. Orpet.

ÓRCHIS (Greek word, referring to the shape of the tuberous roots of certain species). *Orchidàceæ*. The typical genus of the great family of orchids.

Plants perennial by means of simple or palmate tubers: st. simple, erect, terminating in a raceme or spike, with few to many rather small fls., and bearing several lvs., with long sheaths: bracts often foliaceous: sepals all similar, connivent or spreading; petals often smaller, entire; labellum 3-lobed, middle lobe entire or parted, base spurred; column very short or none; stigma plane, not produced (Habenaria).—About 70 species, all terrestrial and natives of the northern hemisphere, chiefly in Eu. and Asia, with 2 species in N. Amer. For *Orchis spectabilis*, Linn., see *Galeorchis*.

Orchises are not showy, and they have no horticultural standing, but lovers of hardy orchids collect them and try to cultivate them, usually with little success. They will probably thrive under the treatment given Galeorchis, of which F. W. Barclay writes: "The American species of Orchis are woodland plants, requiring rich leaf soil, with rather heavy shade, and that even condition of moisture characteristic of deep woods. Where these conditions cannot be supplied, the plants invariably prove short-lived." See also discussion on terrestrial orchids, page 2392.

hircìna, Crantz (*Himantoglóssum hircìnum*, Spreng.). Fl.-sts. 1–2 ft. high, bearing a loose raceme 4–8 in. long: fls. greenish white, exhaling a disagreeable odor; middle lobe of the labellum long, strap-like and twisted, lateral lobes much smaller: lvs. few near the bottom of the scape, oblong-lanceolate. May, June. Eu. and N. Afr. G.W. 2, p. 351.—Advertised by Dutch bulb-growers.

The following species are advertised in Amer. by European dealers, but are not known to be cult. in Amer. Most of them are hardy European plants. The synonomy of the group is somewhat confused. *O. Brancifórtii*, fls. purple.—*O. foliòsa*, large, leafy spikes of purple fls. G. 13:183; 26:296; 35:465. G.M. 50:709.—*O. fúsca*, purple- and rose-colored fls.—*O. latifòlia*, spotted lvs. and purple fls. G. 6:229. Gn.W. 20:599.—*O. longicórnis*, fls. rich purple. N. Afr.—*O. maculàta*, fls. lilac-purple.—*O. máscula*, fls.

purple, in long spikes.—*O. militàris*, fls. purple.—*O. Mòrio*, fls. purple and green.—*O. pállens*, pale sulfur-yellow.—*O. papilionàcea*, fls. purple and white.—*O. provinciàlis*, long spikes of pale lemon-yellow fls.—*O. Robertiàna*, fls. purple, brown and white, in large spikes.—*O. sambucìna*, fls. yellow.—*O. undulatifòlia*, fls. white- and rose-colored.

Heinrich Hasselbring.

OREOCÀRYA (Greek, *mountain nut*, referring to habitat and the nutlets comprising the fr.). *Boraginàceæ.* About 20 species of mostly biennial rough or hispid herbs separated in recent years from Eritrichium and Krynitzkia. They are natives of W. N. Amer. and Mex. They are scarcely known as horticultural subjects, as only now and then are some of them transferred to gardens. They are white- or yellow-fld., the blossoms being on the order of myosotis: lvs. alternate, narrow: roots woody: fls. in crowded thyrse-like or paniculate clusters, the calyx 5-parted; corolla salver-form, crested in the throat, 5-lobed; stamens 5, not exserted, often dimorphic; ovary deeply 4-lobed, becoming 4 nutlets. Many species are native in the Wyo.-Colo.-Utah region. L. H. B.

OREOCÈREUS (the mountain Cereus). *Pilocèreus* in part of authors. *Cactàceæ.* Usually large columnar plants with strong armaments and producing long white hairs or wool like Cephalocereus, but with very different fls.: ovary and fl.-tube covered by numerous imbricating bracts with their axils filled with long woolly hairs; stamens numerous, as long or longer than the petals; style long exserted.—Two species are in cult. and are described below. They are cult. the same as Pilocereus.

Celsiànus, Riccob. (*Pilocèreus Celsiànus*, Lem. *P. fossulàtus*, Lab.). Columnar, in the gardens simple, hardly more than 4 ft. high, 3 in. diam.: ribs 10–17, bright green: areoles bearing long (2 in.) white hair; radial spines usually 9, the lower one, the longest, less than 1 in. long; central usually 1, sometimes 4, the longest sometimes 3 in. long, all yellow: fls. not known. Andes of Bolivia.

Var. **Bruénnowii,** Brit. & Rose (*Pilocèreus Bruénnowii*, Haage, f. *P. Celsiànus Bruénnowii*, Schum.). St. stouter: wool brownish, more copious; spines stronger and darker.

lanàtus, Brit. & Rose (*Cáctus lanàtus*, HBK. *Pilocèreus Daùtwitzii*, Haage. *P. Haàgei*, Poselg.). Columnar, reaching 5 ft. in height, 4 in. diam.: ribs 25–30, low, obtuse: areoles close together, bearing over 20 needle-like, spreading and interlocking spines, and also copious long, white, curled hairs which cover the whole upper part of the plant, like a spider's web.: cephalium and fl. not certainly known. N. Peru. Ecuador. G.C. 1873:7. F.S. 21:2163.

J. N. Rose.

OREÓCOME: *Selinum.*

OREODÓXA (Greek, *mountain glory*). *Palmàceæ.* The royal palm, cabbage palm, and a very few others, from Florida to northern South America, comprising the finest species of palms in cultivation; pinnate-leaved, with tall columnar boles.

The genus Oreodoxa, as formerly understood, has recently been divided, and the Florida and West Indian royal and cabbage palms have been separated as Roystonea and the name Oreodoxa has been reserved for South American species. This separation proceeds on the basis of the botanical distinctness of the two groups and also for nomenclatorial reasons. Oreodoxa was established by Willdenow in 1804 for 2 Venezuelan species, neither of which is congeneric with the W. Indian royal palms. The type species, *O. acuminata*, Willd., is associated by some authors with Euterpe, by others with Œnocarpus. (See O. F. Cook, Science II. 12:479 (1900); Bull. Torr. Bot. Club, 28:549 (1901), and 31:349 (1904); also Cook & Collins, Ec. Pl. Porto Rico). Nevertheless, this disposition has not been accepted by other palm students, as Beccari, and Dammer & Urban; and until something like an agreement is reached (and without expressing any opinion on the merits of the case), it is better for a cylcopedia of horticulture to hold to a conservative practice. For Beccari's recent treatment, see Pomona College Journ. Econ. Botany, May, 1912.

2675. Royal palm.—Oreodoxa regia.

As usually defined, and as understood by Martius (not Willdenow), Oreodoxa comprises spineless palms, the solitary erect robust trunk cylindrical or swollen at the middle: lvs. terminal, equally pinnatisect; segms. narrowly linear-lanceolate, narrowed at the apex, unequally bifid; midnerve rather thick, scaly beneath; margins not thickened, recurved at the base; rachis convex on the back, sulcate toward the base, and acute toward the apex above; petiole half-cylindrical, sulcate above; sheath long: spadix rather large, with long, slender, pendent branches; spathes 2, the lower broad, laterally carinate, shorter than the spadix, the upper complete semi-cylindrical, ventrally fissured: bracts and bractlets scaly: fls. small, white, in scattered glomerules: fr. obovoid or oblong-ovoid, small, violet; seed small, rounded, depressed, or obovate and somewhat curved, with sub-basal embryo and uniform albumen.

The two well-known Oreodoxas are the royal palm (*O. regia*) and the cabbage palm (*O. oleracea*). Both are stately trees. While it is often difficult to distinguish immature specimens of the royal and cabbage palms, in age they are distinct. *O. regia* has staminate flowers which, in bud, entirely inclose the stamens, while in *O. oleracea* the stamens protrude before the flower opens. In the latter species, also, the fruit is nearly twice as long as wide, while in *O. regia* it is not more than a third longer than wide. The character of trunk swelling, usually applied as a distinguishing mark, is likely to break down in some wild plants. The royal palm is one of the grandest of pinnate palms, growing to a height of over 100 feet with immense plumy feathery leaves and a straight white trunk. It is a magnificent tree for extreme southern Florida for avenue planting, and is valuable in all sizes, but especially when 4 feet or over in height. The form of it native in Florida is by some regarded as a distinct species. The cabbage palm is cut down when three years old for the central leaves, which are tender and edible. In southern California, the royal palm lives for years but without attaining any size, and is therefore not accounted a success there. Because of the original error in assigning the West Indian royal palms to Oreodoxa of Martius, which itself is untenable, the names of these plants and their relatives are badly mixed.

A. *Staminate fls. bearing columnar pistillodes that are 3-parted at the apex (Oreodoxa).*

Sancòna, HBK. St. 120–150 ft., smooth, glabrous, grayish black: lvs. pinnate; lfts. membranaceous: wood very hard, used in building houses. Colombia.—Apparently cult. only in S. Calif. within the U. S. Franceschi says it has brownish lf.-stalks and is more tender than *O. regia* or *O. oleracea.*

AA. *Staminate fls. bearing spherical or ovoid pistillodes with sessile stigmas (Roystonea).*

B. *Trunk usually swollen at or above the middle.*

règia, HBK. (*Roystònea règia,* O. F. Cook). ROYAL PALM. Fig. 2675. Caudex 40–60 ft. high.: lvs. 8–10 ft. long; lf.-segms. 2½ ft. long, 1 in. or less wide, linear, acuminate: fr. ovoid, ½in. Cuba, Antigua. G.F. 9:155. S.S. 10:505. G.C. III. 17:239; 27:297. A.F. 12:311. G.M. suppl. Oct. 1, 1892.—Commonly planted in the W. Indies; also elsewhere. The form in Fla. (separated as *Roystonea floridana,* O. F. Cook) is said to lack the characteristic bulge in the trunk and to grow in reach of tide-water rather than on the hills or elevated lands. In the Everglades this native palm sometimes reaches 125 ft. in height, with lvs. 15 ft. long. It is tall and slender when young.

Borinquèna, Reasoner (*Roystònea Borinquèna,* O. F. Cook). The ROYAL PALM of Porto Rico. Trunk usually with a prominent bulge, but sometimes slender, about 30–35 ft. tall; otherwise much as in *B. regia* but differing in having more densely branched infl., which is covered with a dark brown pubescence: seeds about ½in. long, distinctly narrower than those of *O. regia* and somewhat flattened or concave on the back. Porto Rico, on limestone hills.—According to Reasoner it does well in extreme S. Fla. outdoors.

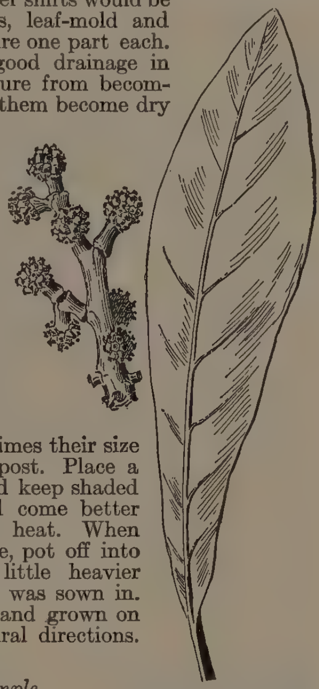
BB. *Trunk not swollen at the middle, usually perfectly cylindric.*

oleràcea, Mart. (*Arèca oleràcea,* Jacq. *Eutérpe caribæa,* Spreng. *Roystònea oleràcea,* O. F. Cook). CABBAGE PALM. Caudex 100–120 ft. high: lvs. 10–14 ft. long; lf.-segms. lanceolate-linear, acuminate, 3 ft. long, 1½ in. wide: fr. obovoid-oblong, ¾in. W. Indies.—Cult. in S. Fla. L. H. B.†

OREÓPANAX (i. e., *mountain Panax*). *Araliàceæ.* Tropical American shrubs and trees grown in the greenhouse.

Leaves simple or compound, entire or toothed, thick: fls. in dense heads which are arranged in racemes or panicles; calyx with minute or obsolete limb; petals 4–7, usually 5, the stamens of the same number and with ovate or oblong anthers; ovary 3–7-loculed, the styles rather long and bearing a flat, not thick, stigma: fr. globose and berrylike.—Some ninety species-names have been referred to this genus, but the number of species is probably much less than this number. In the trade, the species of Oreopanax are usually known as aralias, but in the Aralia tribe the petals are imbricate in the bud, whereas in Oreopanax they are valvate. Few species of Oreopanax are known in cult. Harms (Engler & Prantl, Pflanzenfamilien) divides the species into 3 groups,—lvs. digitate, lvs. lobed, lvs. not lobed. The species described below are those which are now most often mentioned in gardening literature, but only the first seems to be much known here.

Propagation is by cuttings and seeds, any time during January, February and March, the earlier the better. Half-ripened growth of the extreme tops should be placed in a warm propagating-bed with a bottom heat of about 80°. Keep them covered with glass and give sufficient moisture and plenty of shade. When the roots are about ½ inch long, they may be lifted carefully and potted off into 2- or 2½-inch pots, using a mixture of loam, leaf-mold and peat in equal parts, adding enough sand to make it friable. Keep them shaded close and moist until well established, when they may be brought out into full sun. Increase their pot room until they are in 6- or 7-inch pots. They can be kept in fair condition for some time if fed with liquid manure once or twice a week during the spring and summer. During the summer, they will need syringing on all bright days. Always give enough ventilation to keep the growth from becoming too soft, or the atmosphere from becoming too humid. They thrive in an intermediate temperature, in winter from 55° to 60° with a 15° rise during bright days; in spring and summer 60° to 68° for night, with 75° to 80° with sun. They will require some shade when the sun becomes powerful, but not so much as to make them soft. A good compost to use for bigger shifts would be fibrous soil four parts, leaf-mold and well-decayed cow-manure one part each. Give them plenty of good drainage in order to keep the mixture from becoming sour. Do not let them become dry at the roots. In the winter they will need less water and syringing. Keep thrips down by syringing and fumigations.—Oreopanax can also be increased from seed. This seed can be secured through some of the European firms in the spring. It may be sown in pans, using a mixture of loam, peat and sand in equal parts. Cover the seeds about three times their size with finely sifted compost. Place a glass over each pan and keep shaded and moist. They will come better if placed over bottom heat. When large enough to handle, pot off into small pots, using a little heavier mixture than the seed was sown in. They may be shifted and grown on under the above cultural directions. (J. J. M. Farrell.)



2676. Oreopanax reticulatum. Properly Meryta Denhamii. (×¾)

A. *Lvs. all simple.*

reticulàtum, Decne. & Planch. (*Aràlia reticulàta,* Willd.). Fig. 2676. Small tree, with alternate, thick, entire, oblanceolate lvs. 12–18 in. long, somewhat revolute on the margin, strongly alternate-veined and reticulated with shades of green: fl.-heads spherical, nearly or quite an inch diam. S. Amer.?—A handsome plant for foliage.

AA. *Some of the lvs. strongly digitately lobed or angled.*

Sanderiànum, Hemsl. Shrub or small tree, with habit of *Fatsia papyrifera:* lvs. glabrous, thick and glossy, long-stalked, triangular-ovate in outline, on young shoots deeply 3-lobed but on flowering plants cordate and entire: fls. minute, in small, globose heads, which are arranged in racemose panicles. Guatemala. G.C. III. 13:451. A.F. 8:1283.

AAA. *Some or all of the lvs. digitate.*

Epremesniliànum, André. Shrub of striking habit: lvs. large, long-stalked, digitate, the lfts. 7–9, oblong or lanceolate and usually tapering at either end, the middle ones deep-lobed: fl.-heads in a spike. Origin unknown; perhaps a garden form of *O. dactylifolium,* Hort., in which each of the 7 lobes is usually lobed. R.H. 1884, pp. 320, 321. Gn. 29, pp. 354, 355; 30, p. 447.—Named for Count Eprémesnil, Dieppe, France. Well-grown plants resemble *Fatsia japonica* (*Aralia Sieboldii*).

Andreànum, Marchal. Shrub, with variable foliage: lvs. elliptic to roundish, stalked, the lower surface and petioles red-tomentose, varying from angled to deeply digitate and the divisions pinnatifid: fl.-heads globular, in a terminal raceme. Ecuador. R.H. 1882, pp. 524, 525.

Thibaûtii, Hook. Small tree, stellate-pubescent on the young parts: lvs. long-stalked, 5–7-foliolate, the lfts. lanceolate or oblanceolate, entire, 6 in. or less long, dark green: fl.-heads ⅓in. diam., in a terminal raceme 1 ft. long. Mex. B.M. 6340.

O. pedunculàtum was once listed in Calif., with following description: "lvs. palmate, tinged with red; makes a fine foliage plant. Guatemala." It turns out to be Kœlreuteria paniculata.—*O. trílobum*, Hort., a plant offered abroad, may belong here.

L. H. B.

ORÍGANUM (ancient Greek name said to mean *delight of mountains*). *Labiàtæ.* Marjoram. Sweet herbs; and a few species grown in rock-gardens and borders for the ornamental foliage and flowers.

Perennial herbs or undershrubs, with fls. in 2-fld. whorls, rarely 6–10-fld., crowded into globose or oblong spikelets which are disposed in terminal corymbs or panicles: bracts colored and larger than the calyx, or green and smaller; calyx various, 5-toothed or 2-lipped; corolla 2-lipped, the upper or posterior lip 2-lobed or emarginate, the lower 3-lobed; stamens 4, included or exserted; style 2-lobed: nutlets ovoid or oblong, smooth.—About 30 species, largely in the Medit. region, but also in extra-Trop. Asia. Botanically these plants are closely allied to the thyme, but the fls. of marjoram are borne in bracted heads, while those of thyme are borne in few-fld. whorls which are axillary or spicate above. By some authors, the genus is divided into Origanum, with 5-toothed and more or less 13-nerved calyx, and Majorana with oblique calyx-mouth, the upper lip entire and the lower one small or wanting.

The sweet marjoram is *O. Majorana* (or *Majorana hortensis*), not uncommon in gardens. The pot marjoram appears to be very little known in this country. It is commonly referred to *O. vulgare*, although sometimes to *O. Onites*. The former is probably the species concerned, although it is not impossible that both species are confused in this horticultural name, pot marjoram.

Cultivation.—Sweet or annual marjoram (*Origanum Majorana*) is a native of the countries bordering the Mediterranean sea. It is an erect branching perennial, bearing grayish green rounded or oval leaves, small whitish flowers in terminal clusters which appear in midsummer, and little oval dark brown seeds. The plant has a pleasing odor and warm aromatic bitterish taste, due to a volatile oil which is soluble in water, is officinally credited with tonic and gently excitant properties, and, as an infusion, is employed in domestic medicine to "bring out the rash" in such diseases as measles. More frequently than in medicine, however, its green parts are used as a condiment, being highly esteemed as a seasoning for soups, stews, meat-pies and dressings. In the garden this plant is treated as an annual, hence the name "annual marjoram." This practice became necessary since the plants are prone to winter-kill unless carefully protected. Its propagation is also somewhat precarious, owing to the small size of the seeds and the tenderness of the seedlings when exposed to the sun. Shade, therefore, until the plants are well rooted is usually necessary. Successional plantings may be made throughout the spring; sometimes transplanting from hotbeds or coldframes in May or June is practised. The plants should stand 6 inches asunder in rows 12 inches apart, in light and dry but good soil, be kept clean throughout the season, and harvested for winter use just before flowering, the plant being cut close to the ground and hung in a cool, airy place to dry. If planted early, leaves may be gathered in late spring. According to Dreer, American-grown seed is better than imported seed for winter use, as it makes more bulk, while imported seed is better when the plants are to be cut green for summer use.—Pot marjoram (*Origanum vulgare*), a branching hardy perennial, about 2 feet tall, bearing in midsummer pink or purple flowers, and small brown oval seeds, grows wild on the borders of European woods. The highly aromatic leaves and the young shoots gathered just before blossoming are used like those of sweet marjoram. The plant is of easy culture, succeeding in all warm garden soils. It may be propagated by seed, but, where established, division in spring or early autumn is generally practised. The plants should be set 10 inches asunder in rows 15 inches apart, and kept well cultivated. Dwarf pot marjoram, a variety that comes true from seed, bears large heads of whitish flowers, and is often used as an edging plant. (M. G. Kains.)

A. *Spikelets erect.*

B. *Calyx of 5 nearly or quite equal teeth: fl.-bracts medium in size, often colored.*

vulgàre, Linn. Rootstocks nearly horizontal: plant more or less hairy: lvs. stalked, broadly ovate, subserrate or entire, broadly rounded at the base or subcordate: fls. purplish (varying to pink or nearly white), in corymbed clusters or short spikes; bracts purplish, about the length of the calyx; corolla longer than calyx; 2 or 4 of the stamens exserted.—Cult. in old gardens; also wild along eastern roadsides and in fields, naturalized from Eu. An erect herb, 1–2½ ft. high, aromatic. It runs into several forms, one of them being var. **aùreum,** Hort., with golden or yellow foliage.

BB. *Calyx oblique or 2-lipped: fl.-bracts medium or small, not prominently colored.*

C. *Lvs. stalked.*

Majoràna, Linn. (*Majoràna horténsis,* Moench). Sweet Marjoram. Annual Marjoram, from the method of cult., although the plant is perennial. Nearly glabrous, 1–2 ft.: lvs. oblong-ovate, entire, obtuse, tomentose: fls. purplish or whitish; spikelets oblong, 3–5 in a cluster. Eu.

CC. *Lvs. not stalked.*

Onìtes, Linn. (*Onìtes tomentòsa,* Raf. *Majoràna Onìtes,* Benth.). Perennial: st. erect, nearly simple, hirsute: lvs. sessile, ovate, subserrate, villous or tomentose, mostly cordate at the base: fls. as in *O. Majorana* but a little larger; spikelets ovoid, very numerous in a dense cluster. S. E. Eu., Asia Minor, Syria.

AA. *Spikelets nodding: fl.-bracts large, often colored, usually concealing the calyx.*

sipylèum, Linn. (*O. hýbridum,* Mill.). Woody and procumbent at base, the upright branches very villous: lvs. short-petioled, entire, the lower ones suborbicular and hairy, the upper ones ovate, glabrous and glaucous; floral lvs. small: spikes oblong, solitary or in 3's, nodding, the bracts ovate and colored; calyx glabrous, the 3 upper teeth longer; corolla pink. Levant; named for Mt. Sipylos.—A useful little plant for rock-work and dry places; 8–16 in. high; fl.-heads rose-color.

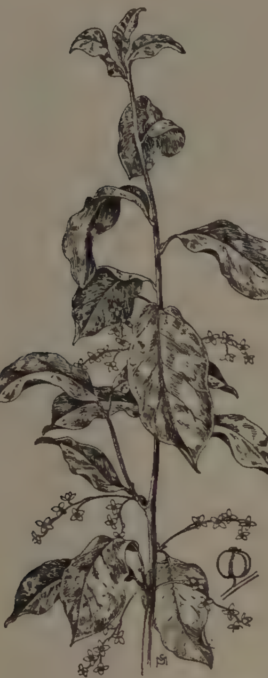
pulchéllum, Boiss. Perennial, grayish pilose, the sts. ascending: lvs. ovate, obtuse, entire, the lower ones short-petioled and the others sessile: spikes nodding, ovate or oblong, the bracts reddish, ovate, glabrous or ciliate; fls. rose-colored; calyx glabrous, the throat bearded, upper lip repand-tridentate, the lower very short and 2-lobed; corolla-tube not gibbous, twice exceeding calyx. S. E. Eu. and eastward.—Said to be a pretty shrub-like little plant with fl.-heads resembling small hops.

O. Dictámnus, Linn., from Crete (Crete Dittany), is a tender species with entire woolly mottled lvs. and purplish or pink fls. in hop-like heads.

L. H. B.

ORÍXA (Japanese name). *Rutàceæ.* Deciduous shrub, with alternate petioled almost entire lvs., and greenish inconspicuous diœcious fls. with 4 sepals and 4 minute petals, the staminate fls. in racemes, the pistillate fls. solitary: fr. consisting of 4 dehiscent pods, each containing 1 black subglobose seed. It has proved hardy in Mass., but has no decorative merit except its bright green foliage, which is not attacked by insects or fungi, and has a strong disagreeable odor like that of ptelea. Orixa seems to grow in almost any soil. Prop. by greenwood cuttings; also by layers and root-cuttings and by seeds. The only species is **O. japónica,** Thunb. (*Celástrus Oríxa,* Sieb. & Zucc. *Ìlex Oríxa,* Spreng. *Othèra Oríxa,* Lam.). Fig. 2677. Shrub, to 8 ft., with spreading branches pubescent when young: lvs. obovate to oblong, obtusely pointed, entire or finely crenulate, bright green above, finely pubescent beneath, translucently glandular-punctate, 2–4 in. long: fls. small, greenish: pods about ⅓in. long, light greenish brown. April, May. Japan. Gt. 35:1232. I.T. 3:101.

Alfred Rehder.



2677. Orixa japonica. (×⅜)

ORMÒSIA (from Greek, for *necklace:* the brilliant seeds of some species used as beads). *Leguminòsæ.* Necklace Tree. Trees, around the world in the tropics, of 40 or more species, bearing large panicles or racemes of white, lilac or black-purple papilionaceous fls., and often handsomely colored seeds, planted sometimes in warm countries: calyx more or less 2-lobed, the 2 upper teeth being somewhat connate; standard very broad, the wings obovate-oblong and oblique; stamens free and unequal; stigma lateral: pod leathery, woody, or fleshy, oblong to linear and compressed, wingless and 2-valved, sometimes septate: lvs. odd-pinnate, with coriaceous lfts.

monospérma, Urban (*Sóphora monospérma,* Swartz. *Ormòsia dasycárpa,* Jacks.). Fig. 2678. Offered abroad: large tree: lfts. 5 pairs, oblong and pointed, 3–4 in. long: fls. blue, ¾in. long in large rusty panicles: pod 1½ in. long, tomentose, 1-seeded; seed somewhat compressed, irregular in shape, ½in. or more longest way, bright scarlet with large angular black patch. W. Indies.

Other species do not appear in accessible lists, but they may be sparingly in cult. *O. coccínea,* Jacks., of S. Amer., is in horticultural literature: lfts. ovate, the margins revolute: fls. blue: pod glabrous and shining; seeds scarlet, with black spot.

L. H. B.

ORNAMENTAL GARDENING, or ornamental horticulture, is that branch of horticulture concerned with cultivating plants of all kinds for show and to satisfy the eye rather than for food. It includes floriculture and also the culture of trees for shade and display. (The culture of trees on a large scale for timber and for other profitable purposes aside from ornament is forestry. The culture of trees in general is arboriculture.) Ornamental gardening includes carpet-bedding and formal gardening in general, while landscape gardening is concerned with making nature-like pictures, or at least with the general plan and setting of the place; it also comprises all that part of floriculture that aims to make grounds and gardens beautiful.

ORNITHÍDIUM (the diminutive for *bird,* from the form of the flower). *Orchidàceæ.* Epiphytic orchids for the warm greenhouse.

Stems leafy, covered with distichously imbricated sheaths, the 1-lvd. pseudobulbs lateral: fls. medium or small, solitary on peduncles which are fascicled in the axils; sepals and petals similar, the sepals free, a little larger than petals; lip 3-lobed, the lateral lobes erect, sometimes inclosing the column; column usually short and footless; pollinia 4, waxy.—About 20 species, in Trop. Amer.

dénsum, Reichb. f. (*Maxillària dénsa,* Lindl.). Pseudobulbs oblong, compressed: peduncles densely fascicled; sepals and petals yellowish, the column and lip marked with rose. Mex. B.R. 1804.

fràgrans, Rolfe. Pseudobulbs ovoid-oblong: fls. few, fragrant, white, faintly flushed with mauve; sepals spreading, oblong-linear, rather acute, the petals somewhat connivent, lanceolate-linear, acute; lip 3-lobed, dull mauve, the lateral lobes small, the middle lobe reflexed, quadrate-oblong, truncate or emarginate.

O. bícolor, Rolfe. Pseudobulbs ovoid, tufted: fls. bright yellow, with a crimson blotch on the front lobe of lip. Colombia.

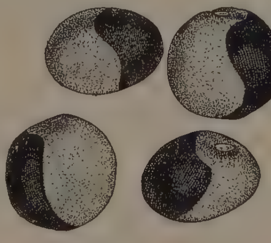
George V. Nash.

ORNITHOCÉPHALUS (Greek, *bird* and *head* in allusion to the aspect of the column). *Orchidàceæ.* Epiphytic orchids, the most striking feature of which is the long slender rostellum.

Cespitose herbs with fleshy lvs.: sepals and petals free, spreading; upper sepal concave; labellum subsessile, 3-lobed, lateral lobes broad and thickened, middle lobe elongated; column short with the rostellum conspicuously elongated; pollinia 4.—About 20 species from Brazil to W. Indies and Mex. The geographical range of the species herein described indicates an intermediate temperature. They may be treated like cattleyas.

grandiflòrus, Lindl. A dwarf compact epiphyte: lvs. distichous, oblong, obtuse, about ⅗in. long: scape from the axil of the lvs.; fls. small, whitish, about ⅘in. across, borne in racemes; sepals and petals similar, blotched at base with emerald-green; labellum 3-lobed, somewhat rounded, saccate, keeled beneath. Brazil.

multiflòrus, Rolfe. Plant densely cespitose: sts. 2⅖ in. high, diphyllous: lvs. lanceolate or oblong, somewhat fleshy, about ⅘in. long: raceme slender, flexuose, 3⅕ in. long; fls. numerous, white; sepals reflexed, ovate, concave; petals spreading; labellum pandurate, obtuse, concave above the middle, 1⅗ in. long, with a suborbicular callus. Brazil.



2678. Seeds of Ormosia monosperma. (×1)

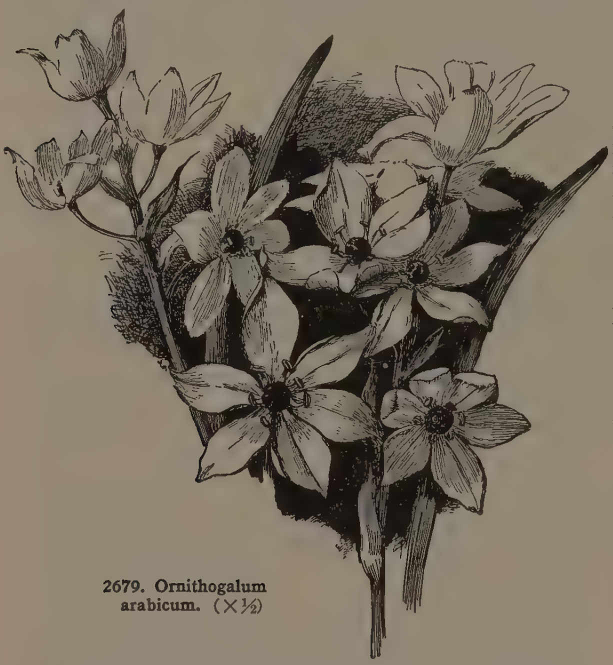
Oakes Ames.

ORNITHOCHÌLUS (Greek, *bird* and *labellum*). *Orchidàceæ.* Epiphytic herbs with leafy sts., similar to Aërides: sepals subequal, spreading, oblong; labellum spurred; infl. longer than the lvs.; fls. yellow with bands of brown; pollinia 2.—A few species from India. **O. fúscus,** Wall. Lvs. subacute, narrowed to the sessile sheathing base, about 6 in. long, about 2 in. wide: infl. longer than the lvs.; fls. small, numerous, in racemes, greenish yellow, with bands of brown and with the pectinate lateral lobes of the labellum purple below; sepals and petals oblong.

Oakes Ames.

ORNITHÓGALUM (Greek, *bird* and *milk;* application not obvious). *Liliàceæ.* This genus includes the star of Bethlehem, a dwarf hardy bulbous plant that bears umbels of green-and-white flowers in May and June; also many other outdoor and indoor bulbs.

Bulb coated, giving rise to linear or very narrow lvs. and a simple leafless scape: fls. white, yellowish or reddish, mostly racemose; perianth persistent; tube none; segms. 6, usually spreading; stamens 6, the filaments more or less flattened and in many species unequal, alternate ones being broader at the base; ovary sessile, 3-celled; ovules many in a cell, superposed; style short or long: caps. membranous, loculicidally 3-valved; seeds globose, usually not crowded nor compressed: often the perianth-segms. are keeled and the green color follows the keel.—Probably more than 100 species, widely spread mostly in the eastern hemisphere. They are particularly numerous in S. Afr. Blue and mauve-purple does not occur in the fls. of this genus, according to Baker.



2679. Ornithogalum arabicum. (×½)

Horticulturally, ornithogalums may be divided into hardy and tender groups, and each of these may be subdivided into dwarf and tall. The hardy kinds are considered by English amateurs amongst the choicest summer-blooming bulbs for wild gardening. With the remarkable increase of wild gardens in America, the popularity of these bulbs is likely to increase with us. The common star of Bethlehem, *O. umbellatum,* a dwarf kind, is the only ornithogalum that is common in American gardens. *O. nutans* has escaped from a few premises; in England "it is a very popular species and one of the most easily managed of all the ornithogalums. In borders amongst other named bulbs, however, it becomes a great nuisance, on account of the freedom with which its innumerable bulbils are formed. In a semi-wild or uncultivated spot it is a capital subject for groundwork; it requires no attention whatever, and flowers freely all through April and May." Of the taller hardy kinds *O. latifolium* and *O. pyramidale* seem to be the most desirable. These may be placed among shrubbery and left undisturbed. A particularly robust clump of *O. latifolium* is recorded as bearing over one hundred spikes of flowers on stalks 3 feet high. *O. pyramidale* sometimes makes a perfect pyramid of starry white flowers, the spike 12 to 18 inches long, the flowers an inch across, and a hundred or more flowers in a spike.

The tender kinds in cultivation are chiefly from the Cape of Good Hope, although *O. arabicum* is found in the Mediterranean region. When well grown, the latter is probably the showiest of the genus. The white of the large broad-petaled flowers is set off by a gleaming black pistil, which makes a striking feature. *O. arabicum* is suitable for pot culture in northern conservatories, but perhaps the best way to grow it is in quantity in a frame. The bulbs have a way of remaining dormant for a season or two, a difficulty possibly to be associated with insufficient ripening. It is suspected that there are two varieties, a shy-blooming and a free-blooming kind. This may explain some of its reputation for capriciousness. *O. thyrsoides* is easier to grow and earlier to bloom. With gentle forcing it may be had for Christmas in a moderately warm house. *O. revolutum* is very distinct in having revolute instead of spreading segments. *O. caudatum* is cultivated in dwelling houses under the erroneous name of sea onion. The sea onion is *Urginea maritima,* a plant of the same general appearance but distinguishable in leaf, flower and fruit as follows: *Urginea maritima* has leaves 2 to 3 inches wide: raceme 1½ to 2 feet long: bracts 3 to 4 lines long: flowers white with a brown keel: seeds crowded, disk-like. *Ornithogalum caudatum* has leaves 1 to 1½ inches wide; raceme ½ to 1 foot long: bracts 6 to 9 lines long: flowers keeled with green: seeds not crowded nor compressed. The ornithogalums are increased naturally by the new bulbs. In general, they are plants of easy culture.

INDEX.

arabicum, 1.

tenuifolium, 6.
thyrsoides, 3.
umbellatum, 7.

A. *Segms. of perianth self-colored on front and back, not keeled with color (No. 2 tinged outside).*

B. *Pistil prominent, shining, greenish black.*

1. **arábicum,** Linn. Fig. 2679. Bulb ovoid, 1–1½ in. thick, proliferous: lvs. 5–8, glaucous green, 1–1½ ft. long, ¾–1 in. wide: scape 1–2 ft. long; raceme 6–12-fld., roundish or deltoid in outline, 3–5 in. long and wide; fls. self-colored, odorous; filaments lanceolate, not cuspidate, alternate ones distinctly broader, but not quadrangular on the base. Medit. region. B.M. 728; 3179 and B.R. 906 (as *O. corymbosum*). G.C. II. 19:665. Gn. 22, p. 249; 32, p. 145; 41, p. 377; 49:308 and p. 309. J.H. III. 61:539. Gn.W. 20:592. G. 10:318; 27:249. C.L.A. 5:48.—The blackish pistil is a beautiful and interesting character. The most popular species for pot culture.

2. **Saûndersiæ,** Baker. Bulb large and globose: lvs. many, flaccid, lorate, more than 1 ft. long: peduncle terete, 2–3 ft., bearing many corymbose fls. on pedicels to 2 in. long with greenish lanceolate bracts; perianth white, ½in. long, the segms. orbicular, tinged outside with green; stamens half as long as perianth; ovary blackish green, with a very short style. S. Afr.

BB. *Pistil not a striking feature, dull, smaller.*

C. *Number of fls. in a cluster less than 50.*

3. **thyrsoìdes,** Jacq. Bulb globose, 1½–2 in. thick: lvs. 5–6, lanceolate, 6–12 in. long, 1–2 in. wide, attenuate above, the margin obscurely ciliate: scape ½–1½ ft. high; raceme 12–30-fld., dense, triangular in outline, 3–4 in. wide; fls. self-colored; segms. ovate and strongly imbricate; filaments alternately longer and lanceolate, alternately shorter, dilated above the base and bicuspidate. S. Afr. B.M. 1164 (fls. white, with a brown eye).—In cult., the perianth may be 1 in. long. Var.

aùreum, Ait. (*O. aùreum,* Curt.), has golden yellow fls. B.M. 190. Var. **flavéscens,** Ker, has pale yellow fls. B.R. 305.—**O. kewénse,** Hort., is a hybrid of *O. thyrsoides* and the var. *aureum:* like *O. thyrsoìdes,* but color is bright buff-yellow.

4. **lácteum,** Jacq. Bulb whitish, subglobose, to 1½ in. diam.: lvs. 9 or 10, somewhat fleshy, rosulate about base of st., lorate, 12 in. or less long, the margins lightly ciliate: peduncle strong and erect, 1–2 ft., bearing a dense 20–50-fld. raceme that becomes 6 in. long and about 2 in. wide, the pedicels erect-spreading and the lowermost as much as 1 in. long; perianth ½–¾in. long, scentless; segms. oblong, about ⅓in. wide, milk-white. S. Afr. R.B. 34:307. G.C. III. 57:193.—An interesting and variable species.

cc. *Number of fls. in a cluster of 50 or more.*

5. **latifòlium,** Linn. Bulb globose, 1½–2 in. diam.: lvs. 5–6, ascending, glabrous, fleshy herbaceous, broadly lorate, 12–15 in. long, 1½–2 in. wide in cult.: scape or peduncle strong and erect, 1–2 ft., bearing a raceme 12–18 in. long and containing 50–100 or more fls.; perianth about ½in. long, the segms. milk-white and oblong-oblanceolate; filaments about equal, lanceolate. Tauria, Caucasus, Kurdistan, Arabia, Egypt. B.M. 876. B.R. 1978.

AA. *Segms. of perianth with a green outer face, the outer segms. narrowly margined white.*

B. *Cluster inversely pyramidal in outline.*

6. **tenuifòlium,** Guss. Bulb ovoid, 1 in. thick, simple: lvs. 5–6, narrowly linear, 5–6 in. long, 1–2 lines wide, unspotted: scape 2–3 in. long; raceme 6–10-fld., corymbose or inversely triangular in outline, 2–3 in. long and wide; pedicels ascending; fls. with outer perianth-segms. margined white. Medit. region.

BB. *Clusters quandrangular in outline.*

c. *Number of fls. 12–20.*

7. **umbellàtum,** Linn. Star of Bethlehem. Bulb subglobose, 1 in. thick, bearing numerous bulbils: lvs. 6–9, narrowly linear, 6–12 in. long, 2–4 lines wide, deeply channeled, distinctly spotted white: scape 4–6 in. long; raceme 12–20-fld., quadrangular in outline, 4–6 in. long, 6–9 in. wide; lower pedicels in fr. spreading; fls. white, with outer perianth-segms. margined white. Medit. region. Escaped from old gardens in U. S. G. 5:72; 27:248.

cc. *Number of fls. 3–12.*

8. **exscàpum,** Ten. Bulb, ovoid, ¾–1 in. thick, not proliferous: lvs. 5–6, narrowly linear, 4–6 in. long, 1–2 lines wide, glabrous, spotted, disappearing after the fls.: scape 1–1½ in. long; raceme 3–12-fld., quadrangular in outline, 1½ in. long, 2½–3 in. wide; lowest pedicels in fr. deflexed; bracts ¾–1 in. long, shorter than the pedicels; fls. with outer perianth-segms. margined white; style very short. S. Eu.

AAA. *Segms. of perianth more or less white-faced but keeled with green on the back.*

B. *Blossoms nodding.*

9. **nùtans,** Linn. Bulb ovoid, 1–1½ in. thick, producing offsets freely: lvs. pale green, 1–1½ ft. long, 3–6 lines wide, disappearing after the fls.: scape 8–12 in. long; raceme 3–12-fld., oblong-cylindrical in outline; pedicels shorter than the bracts; fls. white on upper side, green on the back, margined white, the lower ones nodding. Eu., Asia Minor. B.M. 269. Gn. 32:418 and p. 77; 41, p. 376. Gn.W. 21:871.—Sometimes escaped in U. S.

BB. *Blossoms erect or ascending.*

c. *Width of lvs. 3–6 lines.*

10. **narbonénse,** Linn. Bulb ovoid, 9–15 lines thick: lvs. strap-shaped, 1–1½ ft. long, 3–6 lines wide, glabrous, glaucous green, scarcely disappearing before the end of flowering: scape 1–1½ ft. long; raceme 20–50-fld., oblong-cylindrical, 4–8 in. long, 1½–2 in. wide; lowest pedicels 9–15 lines long; fls. whitish, keeled green on the back; filaments lanceolate at base, not squared. S. Eu. B.M. 2510 (striped green back and front). Var. **pyramidàle,** Hort. (*O. pyramidàle,* Linn.), is considered by Baker to be a robust, large-fld. garden form, but it is said to grow wild in Spain and Portugal and may be a distinct species. Fls. white, with a green stripe on back. Gn. 41:376; 73, p. 603.

11. **biflòrum,** Don. Bulb globose, ¾–1¼ in. diam.: lvs. 4–6, somewhat fleshy, linear, attenuate above, concave, 6–12 in. long and 3–6 lines wide: peduncle or scape 6–12 in. high, with a lax 6–20-fld. raceme that is 3–4 in. long, the pedicels strict and erect-spreading, the lowermost in 2's; perianth about ⅓in. long; segms. ovate-lanceolate and subacute, the back with a narrow green stripe; style short (1 line long). Chile, Peru. G. 26:129. —Said to be a good species for greenhouse decoration.

cc. *Width of lvs. 9–18 lines.*

12. **longebracteàtum,** Jacq. Bulb ovoid, 3–4 in. thick: lvs. 5–6, rather fleshy, glabrous, lanceolate, 1½–2 ft. long, ¾–1½ in. wide, persistent until after flowering: scape 1½–2 ft. long; raceme dense, 30–60-fld., oblong-cylindrical, 6–9 in. long, 15–18 lines wide; lowest pedicels 9–12 lines long; fls. whitish, keeled green on the back; bracts 9–15 lines long; filaments alternately linear and lanceolate at the base. S. Afr.

13. **caudàtum,** Ait. Bulb ovoid, 3–4 in. thick: lvs. 5–6, fleshy-herbaceous, lorate, 1½–2 ft. long, 1–1½ in. wide: scape 1½–3 ft. long; raceme dense, ½–1 ft. long; perianth ⅓in. long, white; banded green on face, and keeled green; stamens three-fourths the length of perianth; bracts 6–9 lines long; filaments alternately lanceolate and quadrate at the base. S. Afr. B.M. 805.—Window plant.

AAAA. *Segms. of perianth white, with a brown or greenish yellow eye, revolute.*

14. **revolùtum,** Jacq. Bulb globose, 1 in. or less diam. lvs. 5–6, lanceolate, 6–9 in. long, 6–9 lines wide: peduncle or scape terete and stiff, 1 ft. high, bearing a dense subcorymbose raceme; fls. not keeled with green, white with yellowish eye; segms. oblong and obtuse, ¼in. broad, reflexing or turning back from near the base; style very short and stout. S. Afr. B.M. 653. B.R. 315.

Wilhelm Miller.
L. H. B.†

ORNÍTHOPUS (*bird's foot,* referring to form of pod). *Leguminòsæ.* A few plants allied to Coronilla and Scorpiurus, from the Canary Isls. through Eu. to W. Asia; and also in Trop. Afr. and S. Brazil. They are little known horticulturally. The fls. are very small, whitish, rose or yellow in umbels, papilionaceous; standard nearly orbicular; wings oblong; keel obtuse and nearly straight; stamens diadelphous: pod much exceeding the calyx, separating into 1-seeded joints or parts. They are slender spreading annuals with pinnate lvs. and axillary peduncles.

The genus is known in cult. in the serradella, a forage plant in Eu., but of very small importance in this country. It is *O. sativus,* Brot., of Spain and Morocco: slender-stemmed and much-branched annual, 1½–2 ft., with strong tap-root: lfts. many, ovate: fls. rose-colored, in few-fld. umbels. It is sown in early spring, 40–60 lbs. of seed to the acre. L. H. B.

OROBÁNCHE (old Greek; said to be given because the species strangle or kill the orobus or vetch). *Orobanchàceæ.* Broom-Rape. Parasitic herbs of purple or brown color, without green foliage, growing on the ground and attached to the roots of other plants. Other genera of the family are Aphyllon and Lathræa, which see. In Orobanche, the calyx is deeply divided into 2 or 4 pointed sepals; corolla broadly tubular or bell-shaped, often curved, more or less 2-lipped; stamens 4, in 2 pairs; ovary 1-celled.—About 100 species, if Aphyllon and some others are included, widely distributed, a number of them in Eu. They are scarcely horticultural subjects, although it is possible to grow them. Writing in The Garden (59, p. 93), Francis D. Horner, says that he was able to grow *O. speciosa* 3 ft. 8 in. high, with many showy fls., and that it began to bloom at 8 in. high. He establishes them on the roots of beans. He grows 3 or 4 beans in a 7-in. pot, and when they are 2 or 3 lvs. high and the roots well around the pot, orobanche seeds are sown over the damp surface. Before the beans are pot-bound, they are planted out with the ball of earth unbroken. The orobanche heads will appear in July. It is essential that the beans do not get into bloom before the seed of the parasite is sown, otherwise it will not get a sufficiently early start to ripen. When fls. of the parasite have turned into shades of brown and the stems have fallen, the plants are stored for seed, which is minute. L. H. B.

ÓROBUS (an old Greek name). *Leguminòsæ.* A genus not now kept separate, and referred mostly to Lathyrus, from which it was distinguished largely by its erect habit and lack of tendrils; some of the species now go to Vicia. Five species-names were found by Beal (Study of Genus Lathyrus, Cornell Bulletins) to be offered by American seedsmen: *O. niger* (=*Lathyrus niger*), *O. vernus* (=*Lathyrus vernus*), *O. lathyroides* (probably=*Vicia oroboides*), and *O. albus* and *O. superbus* which are probably horticultural forms of *Lathyrus vernus.* Abroad there are also listed *O. aurantiacus,* which may be *Vicia aurantia; O. canescens, O. azureus, O. varius, O. Smithii* with "creamy yellow fls., dwarf grower," which probably belong in Lathyrus.

ORÓNTIUM (one of many names arbitrarily applied by Linnæus; he probably had in mind some water plant growing in the Syrian river Orontes). *Aràceæ.* A hardy native aquatic plant, which bears in early spring yellow "clubs" on white stalks. The "club" is a cylindrical spadix 1 to 2 inches long.

Spathe usually soon deciduous; fls. hermaphrodite, covering the whole spadix; sepals scale-like, imbricated upon the ovary, usually 4 in the upper and 6 in the lower fls.; ovary 1-celled; ovule solitary, semi-anatropous: fr. a green utricle.—One species, found in swamps and pools from Mass. to Fla., mostly near the seacoast, but extending as far inland as Cent. Pa. and La.

aquáticum, Linn. Golden Club. Lvs. ascending or floating, according to the depth of the water, oblong-elliptic, no distinct midrib, but numerous parallel veins; blade 5–12 x 2–5 in.; stalk 4–20 in. long: scape ½–2 ft. long. B.B. 1:364. L.B.C. 5:402. R.H. 1888:85. Gn. 27, p. 213. G.M. 54:247.—The foliage is handsome, dark velvety green above, silvery below. The plant is very strong and deeply rooted, growing in water 10–18 in. deep. On account of its firm hold on the soil it may be planted in swifter water than most aquatics. It has the fault of being difficult to eradicate when firmly established. F. W. Barclay.

ORÓXYLUM (Greek, *a mountain tree;* nevertheless it grows anywhere from sea-level to an altitude of 3,000 ft.). Also written *Oroxylon. Bignoniàceæ.* An ornamental tree from S. Asia, with large opposite twice- or thrice-pinnate lvs.: fls. in terminal panicles; calyx leathery, campanulate, truncate or shortly toothed; corolla campanulate, white or purplish with 5 crisped and toothed lobes imbricate in bud; stamens 5, slightly exserted; disk large, fleshy: fr. linear, septicidally dehiscent; seeds broadly elliptic, compressed with a broad transparent wing.—A very striking plant with bold much-divided glossy foliage and ample terminal panicles of large white or purple fls. followed by very long and narrow pendulous caps. It is cult. outdoors in Calif, and in Eu. in greenhouses. Demands rich soil. Prop. by seeds and by cuttings with bottom heat.

índicum, Vent. (*Calosánthes índica,* Blume). Tree, to 40 ft.: lvs. 2–4 ft. across; lfts. ovate, entire, glabrous, about 5 in. long: racemes peduncled, to 10 in. long; fls. 2½ in. long and 2–3½ in. across: caps. 1–3 ft. long and 2–3 in. wide, compressed. India to Cochin-China and Malaya. Wight, Icon. 1337.

O. flàvum, Rehd.=Radermachia pentandra.

Alfred Rehder.

ORPINE, or **STONE CROP:** *Sedum,* particularly *S. Telephium.*

ORRIS-ROOT, or **IRIS-ROOT:** *Iris florentina* and others.

ORTHOCÁRPUS (Greek, *straight fruit,* which distinguishes this genus from Melampyrum). *Scrophulariàceæ.* Annual and perennial herbs, which may be transferred to gardens: lvs. alternate, incised, those in the infl. sometimes colored: fls. mostly white, yellow or cream-colored, sometimes marked, in spikes; corolla tubular, 2-lipped; calyx 4-cleft; stamens 4.—Species about 30, W. N. Amer., and 1 in S. Amer. *O. purpuráscens,* Benth., is something like the painted cup (Castilleja). It is a Californian annual, growing a foot high, with gaudy bracts, and crimson or purple corolla 1–1¼ in. long, the lower lip white-tipped and with yellow or purple markings. It is a common and showy plant growing in the Sierra Nevada foothills, the interior valleys and Coast ranges. This plant was offered in 1891. L. H. B.

ORTHÓSIPHON (name refers to the *straight tube*). *Labiàtæ.* Annual or perennial herbs sometimes sub-shrubs, of more than 100 species in the tropics from Afr. to Austral., little known in cult.: lvs. opposite or whorled, glandular-dotted: infl. terminal, sometimes with colored bracts at top, each whorl 2–6-fld., fls. variable in size; calyx unequally 5-toothed; corolla-tube mostly surpassing the calyx; corolla-limb 2-lipped, the upper lip shortly 3–4-lobed and the lower concave or boat-shaped; stamens 4, exserted; ovary deeply 4-lobed, the style filiform and exserted. *O. stamíneus,* Benth., is probably the species most likely to be found in glasshouses: 1–2 ft., glabrous or pubescent, the st. 4-angled: lvs. ovate, acuminate, coarsely toothed, petioled: fls. white or purplish, about 1 in. long, the corolla-tube thrice longer than calyx; stamens much exserted. India. B.M. 5833. G.Z. 29:145.

L. H. B.

ORTHROSÁNTHUS (Greek, *morning flower;* because the fls. open in the morning and fade before noon). *Iridàceæ.* Small plants for indoor use, listed with dealers among bulbs, bearing bright flowers on a scape arising from the clump of narrow leaves.

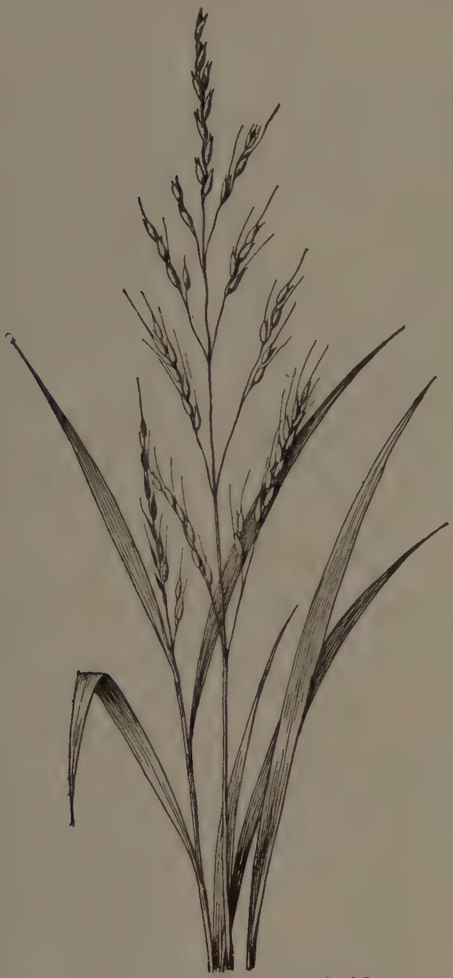
Orthrosanthus is a genus of 9 or 10 species, from Trop. or extra-Trop. Amer. and Austral. Rootstock short: lvs. firm, linear, equitant: clusters many-fld., panicled; fls. pale blue; pedicels so short that the caps. is not protruded from the spathe; perianth-tube very short or none; segms. oblong, nearly equal, spreading; filaments free or connate only at the base; ovary 3-celled; ovules many, superposed; style-branches alternating with the anthers: seeds minute. Very near Sisyrinchium which is a more variable genus, and has longer pedicels.

multiflòrus, Sweet (*Libértia azùrea,* Hort. *Sisyrinchium cyàneum,* Lindl.). Lvs. a dozen or more, 1–1½ ft. long, ⅛–⅙in. wide: panicle 4–6 in. long: caps. obtuse. S. and W. Austral. L.B.C. 15:1474. B.R. 1090.—*O. multiflorus* is a charming plant something like blue-eyed grass or sisyrinchium. It has a tuft of grassy foliage a foot or two high, and sky-blue 6-parted fls. an inch or more across, which open one after another for a week or so. Horticulturally it is classed among tender bulbs, although it has a short thick rhizome.

Wilhelm Miller.

ORỲZA (derived from the Arabic name, *Eruz*). *Gramíneæ.* Marsh plants, with fls. in panicles: spikelets 1-fld., laterally compressed; glumes 2, minute; lemma and palea about equal, keeled, scabrous, the former usually more or less awned.—Six species of the tropics, including *O. sativa*, Linn., the well-known rice of commerce. Dept. Agric., Div. Agrost. 20:49. This is a native of the Old World tropics, and is naturalized in Brazil; cult. extensively in China and India and more recently in the coast region of our southern states. Contrary to the usual supposition, rice paper is not made from rice, but from paper mulberry or bamboo.

A. S. Hitchcock.



2680. Oryzopsis racemosa. (×⅜)

ORYZÓPSIS (Greek, *orusa*, rice, and *opsis*, appearance, from a fancied resemblance to that grain). *Gramíneæ.* Mountain Rice. Mostly tufted perennials, with narrow panicles of rather large greenish one-flowered spikelets.

Glumes thin, nerved, nearly equal; lemma coriaceous, sub-cylindrical, with a short callus at base, and bearing a simple untwisted deciduous awn.—Contains about 24 species of temperate regions. Three of our native species are offered by dealers in wild plants.

racemòsa, Ricker (*O. melanocárpa*, Muhl.). Fig. 2680. Distinguished by its leafy culm, the lvs. broad and flat: panicle simple or compound; lemma blackish; awn about 1 in. long. Rocky woods, New England to Mo.—Blooms late in summer.

asperifòlia, Michx. This and the next have tufted, naked culms, the flat, concave or involute, rough-edged, evergreen lvs. crowded at the base; culms 9–18 in. high, bearing nearly bladeless sheaths; awn ⅓in. long. Northern states to Colo.—Blooms early in spring.

púngens, Hitchcock (*O. canadénsis*, Torr.). Culm 6–15 in.: lowest sheaths leaf-bearing: lvs. involute, filiform; awn very short, deciduous or wanting. Maine to Minn., on rocky hills; rare. Dept. Agric., Div. Agrost. 20:63.

miliàcea, Benth. & Hook. Perennial, 2–3 ft.: blades flat, ⅓in. wide: panicle loose and open, as much as a foot long, with spreading branches; spikelets 1½ lines long, with a deciduous straight awn 2 lines long. Eu.—A form of this (called also *Mílium Thómasii*, Duby, and *Piptathèrum Thómasii*, Kunth) with numerous sterile lower branches of the panicle, is sometimes cult. for ornament.

A. S. Hitchcock.

OSAGE ORANGE: *Maclura.*

OSBÉCKIA (Peter Osbeck, 1723–1805, student of Linnæus, Swedish naturalist). *Melastomàceæ.* About 60 species of herbs, subshrubs and shrubs in the tropical parts of the eastern hemisphere, only seldom cult. for the pink or reddish showy fls. that are borne in heads or panicles or sometimes solitary: usually erect, and scabrous or hispid: lvs. 3–7-nerved, somewhat serrate or entire: calyx-tube urn-shaped or nearly globose, hispid, the limb mostly 5-lobed and the lobes sometimes deciduous; petals commonly 5, obovate; stamens 10 as a rule, the anthers with mostly 2 tubercles at base: caps. small, in the dry calyx-tube. They are grown as warmhouse herbs. Perhaps *O. stellàta*, Wall. is the species most likely to be found in cult.: shrub, 6–7 ft. or less, with 4-angled branchlets: lvs. opposite, ovate-lanceolate, acuminate, 3–6 in. long, ciliate, 5-nerved: fls. lilac-red, in terminal few-fld. clusters; petals 4, nearly or quite orbicular, ciliate, 1½ in. long. India, China. B.M. 8500. J.F. 2:168.

L. H. B.

OSIERS are willows used for baskets and willow-ware in general. Some dogwoods are also sometimes called osiers. The various kinds are described under Salix and Cornus. Osier-culture is generally considered as belonging to general agriculture, rather than to horticulture, and is therefore not treated here.

OSMÁNTHUS (Greek, *fragrant flower*). *Oleàceæ.* Ornamental woody plants grown for their handsome foliage and the white fragrant flowers.

Evergreen shrubs or small trees: lvs. usually opposite, short-petioled, entire or serrate: fls. axillary or terminal, in cymes or short panicles, perfect, polygamous or diœcious; calyx short, 4-toothed; corolla short-tubular, with 4 imbricate lobes; stamens 2, rarely 4; ovary 2-celled: fr. an ovoid drupe with a 1-seeded stone.—About 10 species in E. and S. Asia, and Polynesia, and 1 in N. Amer. Sometimes united with Olea which differs chiefly in its valvate corolla-lobes.

The osmanthuses in cultivation are handsome shrubs with coriaceous rather large leaves and small white very fragrant flowers in axillary clusters followed in the fertile plants by ovoid bluish drupes but rarely produced in cultivation. The hardiest species is *O. Aquifolium* which is hardy in sheltered positions as far north as New York and possibly to Massachusetts. All the others are tenderer and can be grown only in the South and in California. In the North, *O. fragrans* is frequently grown as a greenhouse plant for its very fragrant flowers. It is of the easiest culture in an intermediate temperature. It is almost a continuous bloomer, although ordinarily it should be rested in late winter or summer in order to ripen the wood for fall and winter bloom. Be careful not to overpot, and keep the plant free from mealy-bug. Out-of-doors all the species prefer a place shaded from the mid-day sun. Propagation is usually by cuttings of half-ripened wood in late summer under glass; seeds are rarely obtainable and do not germinate until the second year; grafting on privet, as is sometimes done, is not to be recommended.

Greenhouse treatment of the Olea fragrans of gardens.—This fragrant plant can be grown in a cool house, one that has a night temperature of 45° to 50° in the winter months. The plants should be grown just as cool as possible in the summer months, and allowed to come into flower in their natural way, as they do not take kindly to any kind of forcing. About the first of June, they may be plunged outside in a partially shaded situation where they can be watered and syringed. By September, they may be placed in a cool and airy house where, by receiving care as to watering and ventilation, they will show bloom late in autumn or early winter. When they are through flowering, they may be repotted, using a compost of fibrous soil four parts, well-decayed cow manure one part, leaf-mold one part, and enough of sand to keep it porous.—They will root from ripened points of the young growth placed in sand in a warm propagating-bed. When rooted, they may be potted off into small pots, and grown on in a temperature of 50° to 55°, giving them shade and moisture until they become well established. Give repeated shifts as they fill the pots until they have reached a 7- or 8-inch pot. They may be kept for some time in good vigor by top-dressings and with liquid manure in these pots. When using the compost for these large pots, let the mixture be as lumpy as possible. Do not overlook the importance of giving them plenty of drainage as they will not tolerate anything like a stagnant compost. If the aphis bothers, give light fumigations for two or three nights. When scale shows itself, give a thorough sponging with some good insecticide. (J. J. M. Farrell.)

2681. Osmanthus fragrans. (×½)

A. *Corolla-tube shorter than the lobes or nearly as long: lvs. 1½–5 in. long.*

B. *Lvs. with small teeth or entire, 2½–7 in. long.*

fràgrans, Lour. (*Òlea fràgrans*, Thunb.). Fig. 2681. Small tree, to 30 ft., or shrub: lvs. elliptic to oblong-lanceolate, acute or acuminate, cuneate at the base, finely and sharply toothed or entire, reticulate beneath: fls. very fragrant, in clusters on slender pedicels ½–¾ in. long; corolla divided nearly to the base: drupe ovoid, about ½in. long. Early spring. Himalayas, China, S. Japan. B.M. 1552. L.B.C. 18:1786. Gt. 28, p. 276. G. 3:582. Gn. 19, p. 261.

americànus, Benth. & Hook. (*Òlea americàna*, Linn.). Devil-Wood. Florida Olea. Shrub or small tree, to 40 ft. with whitish bark: lvs. elliptic to lance-oblong, acute, narrowed into the short petiole, entire, lustrous above, 2½–7 in. long: fls. fragrant, in short panicles, on short pedicels or nearly sessile; corolla-lobes spreading, about as long as the tube: drupes ovoid, nearly 1 in. long. Early spring. N. C. to Fla. and Miss. S.S. 6:279, 280.

BB. *Lvs. with few coarse spiny teeth, rarely entire, 1–2 in. long.*

Aquifòlium, Sieb. (*Òlea Aquifòlium*, Sieb. & Zucc. *Òlea ilicifòlia*, Hassk.). Shrub or small tree, to 20 ft.: lvs. oval or ovate to elliptic-oblong, with 2–4 strong spiny teeth on each side, rarely entire, lustrous, 1–2 in. long: fls. fragrant, in axillary clusters, on slender pedicels about ⅓in. long; corolla divided nearly to the base, with reflexed lobes; sepals entire: fr. ovoid, ½–¾in. long. June, July. G.C. II. 7:239 (as *O. ilicifolius*); III. 2:379. S.I.F. 1:82. Var. **myrtifòlius,** Nichols. (*O. myrtifòlia*, Hort.). Lvs. smaller, entire, acute or acuminate. Gn. 50, p. 86. Var. **rotundifòlius,** Nichols. (*O. rotundifòlius*, Hort.). Lvs. about 1 in. long, often obovate, entire or with short obtusish teeth; a dwarf slow-growing form. Var. **atropurpùreus,** Schneid. (*O. Aquifòlium* var. *ilicifòlius purpùreus*, Nichols.). Foliage purplish black while young, later green with purple tinge. Var. **argénteo-marginàtus,** Hort., with white, and var. **aùreo-marginàtus,** Hort., with yellow variegation. —*O. Aquifolium* has often been confused with *O. Fortunei* (see suppl. list) and the true *O. Aquifolium* distinguished as var. *ilicifolia* or *O. ilicifolia*.

AA. *Corolla-tube much longer than the lobes, ⅓–½in. long: lvs. ½–1 in. long.*

Delavàyi, Franch. Shrub, to 6 ft.: young branchlets finely pubescent: lvs. ovate or ovate-elliptic, acute or obtusish, cuneate or rounded at the base, sharply or indistinctly toothed: fls. in terminal, 5–8-fld. cymes, fragrant, white; pedicels short; anthers inclosed in the tube: fr. ovoid, bluish black. Early spring. S. W. China. B.M. 8459. R.H. 1912, p. 173. Gn. 75, p. 178. G. 33:225. V.F. 185. G.C. III. 55:269. G.M. 57:336.

O. armàtus, Diels. Allied to O. fragrans. Shrub: lvs. oblong-lanceolate to lanceolate, remotely spiny-toothed, 3–4 in. long: fls. in axillary clusters, on stout pedicels scarcely ¼in. long. Cent. and W. China.—*O. buxifòlia*, Hort., is probably Olea capensis, Linn., a shrub from S. Afr.—*O. Fórtunei*, Carr. (O. japonicus, Makino). Probably hybrid of O. Aquifolium and O. fragrans. Lvs. elliptic-ovate to oblong-ovate, with few spiny teeth or many small teeth, 3–4 in. long: sepals denticulate. R.H. 1864, p. 70. G.C. II. 6:689; 7:239. Gt. 28, p. 277.—*O. latifòlia* and *O. ligustrifòlia* of the trade are probably phillyreas.

Alfred Rehder.

OSMARÒNIA (derivation doubtful). Syn., *Nuttállia. Rosàceæ*, subfamily *Prùneæ*. Osoberry. Ornamental woody plant grown for its handsome foliage and early-appearing flowers.

Deciduous shrub or small tree: winter-buds stalked, with few imbricate scales: lvs. alternate, short-petioled, entire, with deciduous small stipules: fls. polygamo-diœcious or diœcious, white, in racemes; calyx campanulate; petals spatulate-oblong; stamens 15, 10 inserted with the petals, 5 below, with very short filaments; carpels 5; styles not exceeding the calyx-tube: fr. consisting of 1–5 oblong drupes with thin flesh and smooth stone.—One or possibly more species in W. N. Amer.

The osoberries are usually shrubs with upright clustered stems, bright green generally oblong rather large leaves and with rather small white flowers appearing with the leaves in pendulous racemes followed by bluish black oblong drupes. The flowers resemble somewhat those of *Ribes americanum*. Hardy as far north as Massachusetts in somewhat sheltered positions, but sometimes injured by late frosts, as it leafs and flowers very early. It prefers a humid soil and a partly shaded situation. Propagation is by seeds sown after maturity or stratified, and by suckers.

cerasifórmis, Greene (*Nuttállia cerasifórmis*, Torr. & Gray). Shrub, 6–15 ft., sometimes tree-like: branchlets glabrous: lvs. oblong-lanceolate, acute at both ends, glabrous above, pubescent beneath, 3–4 in. long: racemes short-peduncled, 5–10-fld., glabrous; pedicels with 2 bractlets; fls. about ½in. across; petals about as long as calyx-tube, the triangular sepals half as long: drupe ¼–⅓in. long, bluish black, bloomy. April, May: fr. in July, Aug. Brit. Col. to Calif. G.C. II. 19:309; III. 19:489; 43:266, 267. Gn. 34, p. 78. L.I. 9.—Greene has described 5 more species of which *O. demissa*, Greene, seems the most distinct and is probably occasionally cult. in Calif. It is a low shrub, 2–4 ft. high, with rigid upright sts.: lvs. smaller, mucronate, glabrous, prominently veined: racemes numerous, denser; sepals ciliolate: drupes more rounded, very bloomy. San Francisco Bay region.

Alfred Rehder.

OSMORHÌZA (Greek; referring to the sweet, aromatic, edible roots). *Umbellíferæ*. A small genus of native herbs, 1 to 3 feet high, sometimes called sweet cicely, but the true sweet cicely is *Myrrhis odorata*, a closely allied European plant, the leaves of which have the scent of anise seed and are used in flavoring. Sometimes listed by dealers in native plants.

Perennial, slender, hirsute or glabrous, with thin soft foliage: lvs. ternately compound, the lfts. ovate and toothed: fls. very small, white, in small few-rayed umbels; calyx-teeth obsolete: fr. linear, glabrous or bristly; carpel slightly flattened dorsally or not at all; styles long or short; seed-face from slightly concave to deeply sulcate: root thick, aromatic. By some botanists, the name Washingtonia is used for this genus. The plants thrive in moist more or less shady woodsy places.

A. *Fr. with prominent caudate attenuation (2–4 lines long) at base, very bristly.*

B. *Style a line or more long.*

longístylis, DC. Stout, glabrous or slightly pubescent. Canada to Va. and west to Dakota. B.B. 2:530.—Roots with a stronger smell and taste of anise than *O. Claytonii*. Brotherton says it is a much prettier plant than the next, with larger umbels.

BB. *Style half a line or less long.*

Clàytonii, Clarke (*O. brevistylis*, DC.). Rather stout, villous-pubescent: lvs. 2–3-ternate: rays stout, 1–2 in. long; style and stylopodium half a line long. Canada to N. C. B.B. 2:530.

nùda, Torr. Rather slender, glabrous, 2½ ft.: lvs. somewhat hispid, biternate, the lower ones 5 in. long; lfts. ovate to elliptic, 3-lobed, serrate: rays of umbel, 4 in. or less long, the involucels none: fr. rather more than ½in. long. Calif.

AA. *Fr. without caudate attenuation at base.*

occidentàlis, Torr. (*Mýrrhis occidentàlis*, Benth. & Hook.). Rather stout, puberulent or pubescent: lvs. 2–3-ternate; lfts. 1½–4 in. long: umbel 5–12-rayed; rays 1–5 in. long; stylopodium and style ½–1 line long. Sierras to Wash., east.

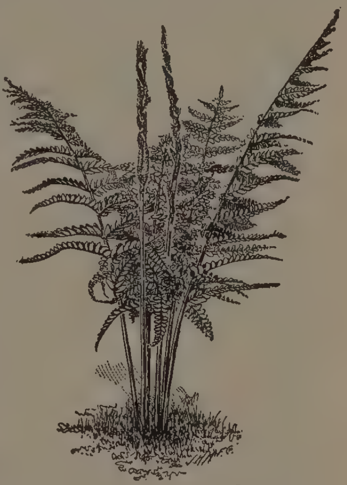
L. H. B.†

OSMÚNDA (from *Osmunder*, a name of a Saxon god). *Osmundàceæ*. A small group of larger ferns, with rather coarse foliage, but highly ornamental from their clustered habit. The sporangia are formed in panicles borne on the veins of reduced lvs., provided with a rudimentary transverse ring and opening vertically.

Osmundas are strong-growing ferns of vigorous constitution, and well adapted for general culture in any fertile soil which is not over-dry. They are deep-rooted ferns and, therefore, require considerable depth of soil. All the species do well in full sunlight, but the most satisfactory position for all the species would be a deeply dug thoroughly enriched border lying north of a wall. *O. regalis* reaches perfection only in rich wet swamps in full sunlight or thin shade, where it may attain a height of 8 feet. *O. Claytoniana* prefers rich peaty soil in moist but not wet, open or partially shaded positions. It may attain a height of 6 feet. *O. cinnamomea* is naturally a fern of the swamp, though not in such wet positions as *O. regalis*. It grows most luxuriantly in partial shade. In a wild state it frequently attains a height of 6 feet. (F. W. Barclay.)

A. *Lvs. fully bipinnate.*

regàlis, Linn. Royal Fern. Growing in clumps 2–10 ft. high, some of the lvs. bearing panicles at their apices; pinnæ 1–2 in. long, rounded at the base and usually blunt. Well adapted for open, moist places. E. N. Amer. and Japan.—Commonly called royal fern, flowering fern or king-fern. *O. japónica*, Thunb., is a form with the sporophylls forming distinct lvs. and soon withering away; various crested forms appear in cult. *O. grácilis*, offered by some dealers, is probably a S. American form of *O. regalis*. *O. palústris* and varieties belong also with *O. regalis*. This is a diminutive form from Brazil, with slender elegant fronds, abundantly produced from a woody rootstock. S. 3:30, and p. 42. G. 37:423. Var. *Màyi*, G.C. III. 40:161, and var. *crispàto-congésta*, a dwarf form, are both forms of *O. palustris*.



2682. Cinnamon fern.—Osmunda cinnamomea.

AA. *Lvs. bipinnatifid only.*

cinnamòmea, Linn. Cinnamon Fern. Fig. 2682. Growing in clusters 2–6 ft. high or even more, the fertile lvs. appearing earliest, entirely covered with sporangia, at first green, but becoming pale, tall, and slender, cinnamon-colored at maturity of the spores, the sterile lvs. growing about a crown from a large creeping rootstock. N. Amer.—Very handsome for decorative purposes, especially for low grounds. The creeping sts. of this species and of the other two osmundas are always covered with a very dense tangled growth of blackish fibrous roots. These are dug up and shaken free of soil, and are then largely used as the matrix upon which to grow orchids and other epiphytes. (See *Osmundine*.)

Claytoniàna, Linn. Interrupted Fern. Lvs. growing in crowns, with the sporangia confined to a few (4–10) of the median pinnæ of the lf., and of a dark brown color. Similar to the preceding, but lacking the tuft of wool in the axils of the pinnæ which characterizes the cinnamon fern. N. Amer., Japan; said also to grow in India.

R. C. Benedict.†

OSMUNDINE. The material now so largely used in this country, and also exported to Europe in quantities for the rooting medium in which to grow epiphytal orchids. Not long ago it was considered necessary to send to England for peat for this purpose, and the word peat used in this connection meant the roots of the bracken, *Pteris aquilina,* when growing in bog-mold. The supply of this became exhausted, owing to the enormous growth of the orchid cultivation, and it was necessary to find a substitute. The first thing tried was the mats of root-fibers of the common *Polypodium vulgare* as found growing on trees in large masses in the moist climate of Ireland. This was composed of a clear light brown fiber with a little humus, and could be torn off the branches in large mats 2 or 3 inches in thickness, and when cut up in suitable pieces made excellent material. However, the supply was soon exhausted and Belgium furnished a quantity which is still being used to some extent. In the meantime the roots of the two species of Osmunda so common and so widespread in this country, *O. cinnamomea* and *O. Claytoniana,* have been found to give very excellent results. These two ferns make huge masses of roots above the level of the soil, sometimes several feet square, and when these are grubbed up, or rather off the ground, sawed in slabs with a cross-cut saw, the fern rhizomes taken out, two grades of material are obtained in which any orchid will grow. The fiber at the base is coarse, black, and contains some earthy matter, and is very suitable for the culture of cypripediums, cœlogynes, and other orchids like the lycastes that are more or less terrestrial. For orchids with the characteristic white aërial roots, the brown upper part of the osmundine is most suitable, as it is sponge-like in color and texture, and will not decay or become unsuitable for at least three years. Care must always be taken in potting orchids to make all firm, or too much moisture will be held in suspension by the osmundine for the roots to ramify and do well.

In cattleyas imported from their native habitats, mats of polypodium are often seen which, together with the orchid roots, enable the plants to anchor securely to the trees. The nature of these fern-masses is identical with that of osmundine except that they are living, whereas the osmundine is not. It is well to use the osmundine as soon as possible after being cut up from the original piece. The pieces are best gathered in autumn, stored in a dry place for the winter's work, and cut up as needed, and if any are not used, place the clumps outdoors for the summer in a shady place where they will grow on indefinitely until wanted for use.

The collection, manufacture, and export of osmundine is now quite a large industry, and the United States is supplying practically all the orchid-growing world with an admirable material, often in thousand-barrel lots, at a price below that of any other kind, with the additional advantage of being more durable than any other. The osmundas named are indigenous to all the eastern states, but the osmundine industry is confined at present to New York because of easy shipment. *Osmunda regalis* is not used, as it is more often found in swamps, and the root-fiber is likely to be sour. Moreover this species does not make the large clumps that the others do, making it unprofitable to gather them.

E. O. Orpet.

OSOBERRY: *Osmaronia.*

OSTEOMÈLES (Greek, *stone apple* or *stone fruit*). *Rosàceæ,* subfamily *Pòmeæ.* Ornamental shrubs, sometimes grown for their graceful foliage and white flowers.

Evergreen: lvs. alternate, pinnate, with linear stipules; lfts. small, entire: fls. in terminal corymbs; calyx-teeth small, acute; petals 5, ovate-oblong; stamens 15–20; styles 5, distinct; ovary inferior, 5-celled, each cell with 1 ovule: fr. a small pome with persistent calyx and 5 1-seeded stones.—Three species in E. Asia and Polynesia. Closely related to Pyracantha and Cotoneaster, but easily distinguished by the pinnate lvs. The S. American genus Hesperomeles, with about 10 species, of which none seems to be in cult., is sometimes united with Osteomeles; it has simple lvs. and is apparently more nearly allied to Cratægus.

These plants are slender-branched shrubs with evergreen small pinnate foliage, and white flowers followed by bluish black berry-like fruits. All three species are in cultivation at least in Europe, but can be grown only in subtropical or warmer temperate regions, the hardiest being probably *O. Schwerinæ.* They prefer a sunny position and well-drained soil. Propagation is by seed sown soon after maturity, but it germinates slowly, sometimes not until the second year, or by cuttings of half-ripened wood in July and August under glass; it also may be grafted on cotoneaster.

anthyllidifòlia, Lindl. Shrub, to 6 ft., or more: young branchlets densely villous: lfts. 13–19, obovate-oblong or oblong, mucronate or obtuse, pubescent on both sides while young, later glabrous and lustrous above, silky pubescent beneath, ⅓–½in. long: corymbs 1–1½ in. across, grayish villous; fls. ½in. across; styles villous: fr. subglobose, bluish black, villous at first, finally nearly glabrous, about ¼in. thick, sweet. Spring. Hawaiian Isls. to Pitcairn Isl. Trans. Linn. Soc. 13:8. —In the Hawaiian Isls. known as "uhi-uhi."

O. Schwerìnæ, Schneid. Shrub, to 10 ft.: lfts. 17–23, oblong or narrow-oblong, acute, ⅙–⅓, rarely ½in. long, slightly pubescent or nearly glabrous: corymbs loose, slightly villous: fr. glabrous. S.W. China. B.M. 7354, G. 27:219, and G.C. III. 50:433 (as O. anthyllidifolia).—*O. subrotùnda,* Koch. Low shrub: lfts. 11–17, obovate-oblong, obtuse: corymbs and calyx silky pubescent. S. Japan, S.E. China. H.I. 27:2644.

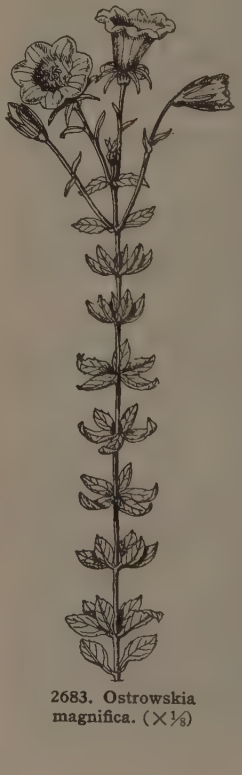
Alfred Rehder.

OSTEOSPÉRMUM (Greek, *bone seed*). *Compósitæ.* A group of South African yellow-flowered shrubs or subshrubs, scarcely in cultivation.

Leaves alternate or rarely opposite: heads many-fld. radiate; pistillate fls. all rays; staminate fls. all disks, with abortive ovules and style; involucre in few rows, the scales free: achenes of the ray drupaceous or nut-like, thick, very hard, glabrous and without pappus.—Thirty-eight species are known, all S. African. In Flora Capensis 3:433–436, the whole group is monographed.

monilíferum, Linn. Shrubby, yellow-fld., grows 2–4 ft. high, and was offered in 1891 in southern Fla. It is a usually unarmed, much-branched, subshrub with leathery lvs. about 1½ in. long. It is known in Austral. as the "bushtick berry." It appears to have dropped out of cult. There are many natural varieties, none of which seems to be known in cult.

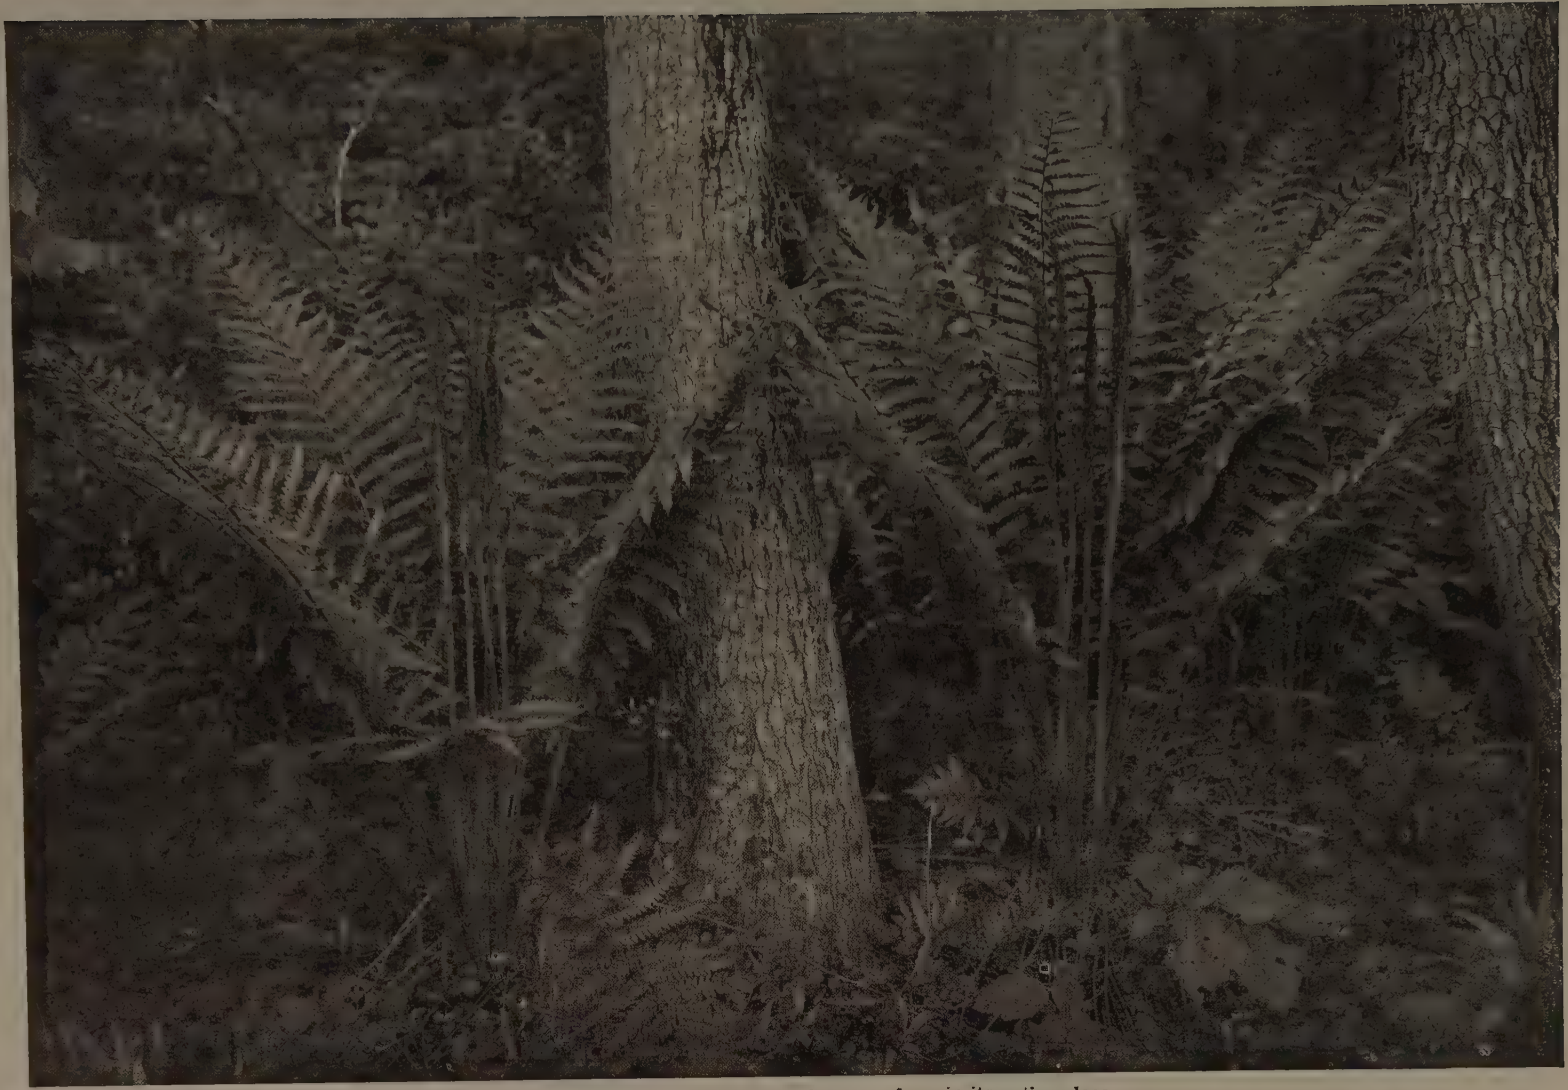
N. Taylor.



2683. Ostrowskia magnifica. (×⅛)

OSTRÒWSKIA (after N. ab Ostrowsky, Russian patron of science). *Campanulàceæ.* GIANT BELL-FLOWER. One species, a very large-flowered perennial herb.

Very closely allied botanically to Campanula but distinguished, according to Hooker, by the whorled lvs., the numerous divisions of the calyx and



LXXX. Osmunda cinnamomea, the cinnamon fern, in its native place.

lobes of the corolla and of the cells of the ovary and stigmas, and by the pores in the caps. double the number of sepals.—The single species is a stately plant of Cent. Asia, first described as recently as 1884, and exhibited in England in 1888. It is a hardy plant, prop. readily by seeds if they are sown as soon as mature, although the plants may not bloom under 3 or 4 years. The long tuberous roots do not bear division well and this is probably one reason why it is not more popular with dealers.

The reason for *O. magnifica* not being catalogued in this country is the difficulty in its successful growing and over-wintering. It requires a light sandy soil, rich in humus and of considerable depth, for the roots of the thick fleshy stock go down deep. A high ground and open sunny exposure are a necessity. After the flowering season, plants like oriental poppies and ostrowskia dry up and should be kept dormant. To prevent growing in autumn, plantations should be protected from excessive moisture. A slopy ground with good drainage is of advantage. For winter cover, dry pine-needles covered with tar-paper are best; leaves will also answer, but by all means avoid manure protection. In early spring, the young growth needs to be protected from late frosts. Treated this way, ostrowskias can be grown in this country and are indeed beautiful border plants.—Propagation is by root- or top-cuttings in spring. Seeds unless sown fresh, require a long time for germination. Seedlings require from three to four years cultivating before reaching a really effective size. (Richard Rothe.)

2684. Ostrya virginiana.—Hop hornbeam. (×¼)

magnífica, Regel. Giant Bell-Flower. Fig. 2683. Tall strict glabrous herb, 4 or 5 ft. or more high, simple, with tuberous roots: lvs. in distant whorls of 4 or 5, ovate, toothed, short-stalked, 4–6 in. long: fls. 4 in. across at the mouth, pale lilac, but varying somewhat in tint; corolla broad-campanulate, the tube 2 in. long and ribbed, the lobes short and broader than long; calyx-lobes 2 in. long, spreading or recurved; floral parts 5–9, usually 7; style large, thick, yellow. E. Bokhara, at 7,000 ft. B.M. 7472. G.C. III. 4:65; 47:400, 401. Gn. 34:604; 52, p. 481; 64, p. 381; 73, p. 375; 75, p. 382; 77, p. 361; 78, p. 374. J.H. III. 60:493. Gt. 50, p. 431. G.W. 4, p. 387. Gn.W. 20:313. G. 30:351; 34:259. G.M. 31:459, 461; 51:765. R.H. 1893:472 and p. 473; 1888, p. 344. I.H. 35:71. S.H. 1:437. G.F. 6:276. A.F. 4:331.

L. H. B.†

ÓSTRYA (ancient name). *Betulàceæ.* Hop Hornbeam. Trees grown for their handsome foliage.

Deciduous: winter-buds conspicuous, pointed: lvs. alternate, doubly serrate, plaited on the straight veins, with oblong or lanceolate stipules: fls. monœcious, in catkins; the staminate catkins slender, pendulous, with 3–14 stamens in the axil of each bract; filaments forked; pistillate upright, slender, with 2 fls. in the axil of each bract; the 2-ovuled ovary crowned by 2 slender stigmas and inclosed in a tubular involucre: fr. a nutlet inclosed by the bladder-like involucre; the inflated involucres loosely imbricated to form a strobile, resembling that of the hop.—Four closely related species in N. Amer., Eu., and E. Asia. From Carpinus distinguished by the bladder-like involucre.

The hop hornbeams are small or medium-sized trees with slender spreading branches forming a round or open head, with handsome bright green foliage, and rather inconspicuous flowers appearing with or before the leaves, followed by the attractive light green strobiles contrasting with the darker foliage. They are hardy and slow-growing, well adapted for planting in dry and exposed localities. The heavy and tough, very close-grained wood is used chiefly for fence-posts, handles of tools and other small articles. Propagation is by seed sown soon after maturity or stratified, otherwise it will usually not germinate until the second year; rarer kinds may be grafted on a common species or on the hornbeam.

virginiàna, Koch (*O. virgínica,* Willd.). Fig. 2684. Tree, to 30, occasionally to 50 ft.: lvs. oblong-ovate, acuminate, glabrous above, pubescent on the veins below, with 11–15 pairs of veins, 3–5 in. long: strobiles slender-stalked, pendulous, 1½–2½ in. long; nutlets spindle-shaped glabrous or nearly so. Dry woods. Cape Breton to Minn., south to Fla. and Texas. S.S. 9:445. Gn. 24, pp. 230, 231.—The lvs. change to clear yellow.

O. carpinifòlia, Scop. (O. vulgaris, Willd. O. italica, Winkl. O. virginiana var. carpinifolia, Schneid.). Tree, to 30 or occasionally 50 ft.: lvs. short-acuminate, pubescent on both sides while young: nutlet ovoid, pubescent at the apex. Eu. R.H. 1905, pp. 188, 189. H.W. 2:18, p. 35. G.C. III. 8:274. Gn. 24, p. 231. G. 7:689.—*O. japónica,* Sarg. (O. virginiana var. japonica, Schneid.). Tree, to 60 ft.: lvs. pubescent beneath: strobiles shorter; nutlets glabrous at the apex. Japan. G.F. 6:384. S.I.F 1:25.—*O. Knòwltonii,* Coville. Tree, to 30 ft.: lvs. ovate or elliptic, obtuse or acute, 1–2 in. long: strobiles 1–1½ in. long; nutlets minutely pubescent. Ariz. G.F. 7:115. S.S. 9:446.

Alfred Rehder.

OSTRYÓPSIS (meaning *Ostrya-like*). *Betulàceæ.* A shrub most nearly related to Ostrya, but frs. tightly inclosed by the 3-parted involucre collected into slender-stalked heads or short racemes: anthers and filaments not divided. In habit and foliage it resembles Corylus. The only species is **O. Davidiàna,** Decne. Low shrub: winter-buds obtuse: lvs. ovate, doubly serrate and slightly lobed, pubescent beneath, 1½–2 in. long: involucre narrowed above the nutlet, ½in. long. N. and W. China, Mongolia. L.I. 3.—Has proved hardy at the Arnold Arboretum. Cult. and prop. like ostrya or corylus.

Alfred Rehder.

OTAHEITE. Tahiti or Tahitian, for an island in the South Pacific, under French rule, as the Otaheite orange and Otaheite mulberry.

OTHÈRA JAPÓNICA: *Ilex integra.*

OTHÒNNA (ancient Greek name, of no particular application here). *Compósitæ.* Herbs and shrubs, of which one is in cultivation as a window-garden plant.

Heads usually yellow, with fertile rays and sterile tubular disk-florets; torus convex or somewhat conical, usually honeycombed; scales of involucre in one series, more or less united to the base, valvate; style of disk-fls. not divided: achenes oval, with bristle-like pappus in many rows or series.—About 80 S. African species, of which only one appears to be in general cult., and this has no established vernacular name in this country, although it is sometimes dubbed "little pickles" because of its cylindrical pulpy lvs.

The plant shown in Fig. 2685 is commonly known as *Othonna crassifolia,* but thereby arises a puzzle in nomenclature. By Linnæus a certain flat-leaved plant was called *Othonna crassifolia.* Subsequently some of the species of Othonna were separated by Jaubert & Spach into a distinct genus, Othonnopsis, distinguished by involucral scales distinct and style of the disk-florets two-parted. One of the plants relegated to this new genus was *Othonna cheirifolia,* Linn., which then became *Othonnopsis cheirifolia,* Jaubert & Spach. Bentham & Hooker consider Linnæus' *Othonna crassifolia* to be a horticultural form of *Othonnopsis cheirifolia.* It was therefore a natural sequence to say that the *Othonna crassifolia* of horticulturists is properly *Othonnopsis cheirifolia*, a statement which the writer made in the revision of Gray's "Field, Forest and Garden Botany."

2685. Othonna crassifolia. A yellow-flowered trailing plant with succulent leaves.

It turns out, however, that the *Othonna crassifolia* of horticulturists is not the *Othonna crassifolia* of Linnæus (if he has been correctly reported). The former plant is a true Othonna. It is the *Othonna crassifolia* of Harvey; but since this name *crassifolia* was used by Linnæus, it leads to confusion to use it again in the same genus, and Harvey's plant might take some other name. In fact, before Harvey's time, the name *Othonna crassifolia* was used by Meyer for still another species. The *O. crassifolia* of Harvey was once described as *O. filicaulis*, but this name also has been previously used in the genus. It seemed to the writer, therefore, as if a new name must be given to the *O. crassifolia* of Harvey and of the horticulturists, and this was done in the Cyclopedia of American Horticulture (*O. capensis*); but under the International Rules, Harvey's name may hold since the other crassifolias are clearly synonyms. What, now, is Linnæus' *Othonna crassifolia?* As early as 1771, this plant was figured in color by Philip Miller as the "*Othonna foliis lanceolatis integerrimis*" of Linnæus' "Hortus Cliffortianus." It was figured again by Edwards in 1818 (B.R. 266). It is an upright or ascending undershrub, with flat leaves reminding one of leaves of the stock. It is described in the European books, but is probably not in commercial cultivation. It is native to the north of Africa. A reproduction of part of Philip Miller's picture of the plant, reduced in size, is shown in Fig. 2686.

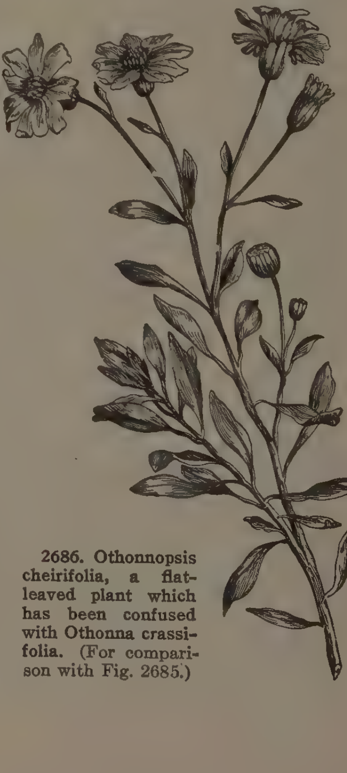
crassifòlia, Harv., not Linn. nor Mey. (*Othónna capénsis*, Bailey). Fig. 2685. Perennial, becoming shrubby at base in its native country, glabrous, with slender trailing or drooping sts.: lvs. 1 in. or less long, fleshy and cylindrical-obovoid, sharp-pointed, either scattered or in clusters: pedicels 2–6 in. long, ascending, slender; heads nearly or quite ½in. across when well grown, the narrow, bright yellow rays wide-spreading. S. Afr. V. 3:117; 10:138.—An excellent plant for hanging-baskets, for it withstands extremes of moisture and temperature. It is readily prop. by planting pieces of the sts. It blooms in nearly all seasons. Fls. open only in sun. L. H. B.

OTTÈLIA (from a name in Malabar). *Hydrocharitàceæ.* Perhaps two dozen fresh-water herbs of the tropics and subtropics of both hemispheres, some of which may be useful as aquatics: lvs. both submerged and floating; the latter with long petioles, the blades lanceolate, ovate or cordate: scape elongated, bearing a fl. in a winged spathe; calyx 3-lobed; petals 3, yellow or white, much longer than calyx-lobes; stamens 6–10 or more, bearing erect anthers: fr. 6-valved, inclosed in the spathe. *O. alismoìdes*, Pers. (*Stratiòtes alismoìdes*, Linn.) is of wide distribution. Afr. to Austral.: perennial, the lvs. arising from the base on long 3-angled petioles; blades broadly cordate, or rounded, obtuse, 2–6 in. or even more long or broad, 7–11-nerved: fls. white, the petals broadly ovate and 1 in. long. B.M. 1201 (as *Damasonium indicum*). G.W. 14, p. 658.—The plants are said to be eaten as pot-herbs by natives. L. H. B.

OURÀTEA (vernacular name in Guiana). Syn. *Gómphia. Ochnàceæ.* Tropical American shrubs and trees of minor importance horticulturally but sometimes grown for the yellow mostly paniculate fls. and evergreen foliage; glabrous: lvs. shining, stiff, alternate, serrate or toothed: sepals and petals 5; receptacle or torus prolonged into a gynophore; stamens 10, attached on base of torus, erect and connivent, the filaments very short; ovary deeply 5- or 6-parted: fr. 5 or less drupes, sessile on the enlarged torus or disk. *O. cuspidàta*, Engler (*Gómphia cuspidàta*, St. Hil.), from Brazil, is mentioned in horticultural literature abroad: shrub 3–6 ft.: lvs. alternate, elliptic, to 6 in. long, minutely toothed: fls. yellow, about ½in. across, in a terminal simple or branched panicle; petals obovate, more or less crisped. *O. olivæfórmis*, Engler (*O. décorans*, Baill. *Gómphia olivæfórmis*, St. Hil. *G. décorans*, Lem.). Tall shrub from Brazil: lvs. broad-lanceolate, shining, finely serrulate: fls. bright yellow, in a large dense terminal raceme; petals obovate and broad. B.M. 5262. G 27:325. Gn. 62, p. 339 (note). J.F. 4:415. L. H. B.

OURÍSIA (Governor Ouris, of the Falkland Islands). *Scrophulariàceæ.* Small herbs, used in alpine gardening and for borders.

Perennial, rarely somewhat woody at the base, usually dwarf, decumbent or creeping a short distance, glabrous or sparsely hairy: lvs. opposite, nearly all radical, crenate or entire: fls. either axillary and solitary, or in a raceme at the apex of a scape, usually scarlet or rose-colored; corolla-tube cylindrical or slightly bell-shaped at the throat, mostly somewhat curved, lobes nearly equal; stamens 4, didynamous; style entire: caps. 2-celled.—About 20 species in Tasmania, New Zeal., S. Amer.



2686. Othonnopsis cheirifolia, a flat-leaved plant which has been confused with Othonna crassifolia. (For comparison with Fig. 2685.)

coccínea, Pers. Hardy herbaceous perennial, sparsely hairy: lvs. mostly radical, long-stalked, heart-shaped, unequally lobed and crenate: scape furnished with 1- or 2-stalked lvs. at the base, and pairs of toothed bracts, from which the pedicels arise; calyx-lobes 5, short, spreading. Chile. B.M. 5335. G.M. 50:633.

macrophýlla, Hook. (*O. robústa,* Col.). To 2 ft. high, from a short decumbent rhizome, mostly somewhat hairy: radical lvs. long-petioled, the blade 1–5 in. long and ovate to orbicular-oblong, crenate, thinnish; st.-lvs. only 1 or 2 pairs, sessile: fls. large (to ¾in. diam.), white or with purplish streaks, in whorls or sometimes in a few-fld. umbel; corolla villous within. the lobes obovate and retuse. New Zeal. B.M. 8295. G.C. III. 45:390. J.H. III. 66:583. Gn. 73, p. 435. G. 34:641.—A good plant for blooming under glass in spring.

O. Cockaynidna, Petrie. A New Zeal. species forming large matted patches, reported in England: sts. 3–6 in. or more long, creeping and rooting: lvs. ovate or ovate-spatulate, obtuse, crenate, with sheathing petioles: peduncles few-fld. and 3–6 in. high, bearing large white fls.

L. H. B.†

OUVIRÁNDRA (Madagascar name meaning *water yam,* referring to the edible tubers). *Aponogetonàceæ.* The lace-leaf or lattice-leaf plant, *O. fenestralis,* is one of the most distinct and interesting plants in cultivation It grows in Madagascar, its skeletonized leaves floating just under the surface of the water. The genus is now included with *Aponogeton,* which see.

ÓXALIS (Greek, *sharp,* referring to the usual acidity of the foliage, which also gives the common name of sorrel). *Oxalidàceæ,* formerly treated as a division of *Geraniàceæ.* Mostly bulbous or tuberous herbs with clover-like leaves, usually cultivated as hanging-basket or window plants for their flowers; a few are used in salads and several South American species like *O. Deppei* (Gn. 8, p. 43) furnish edible roots or tubers.

Annual, or with a bulbous, tuberous or creeping, perennial rootstock: lvs. alternate, mostly digitately compound (3-foliolate in the native species): peduncles axillary, 1- to several-fld.; sepals and petals 5; stamens 10, monadelphous at base, 5 longer and 5 shorter; ovary 5-celled; several ovules in each cell; styles 5: caps. loculicidally dehiscent.—Over 400 species mostly of S. Afr. and the warmer parts of Amer. The fls. usually close at night and in cloudy weather, and the lvs. "sleep" at night (Fig. 2690). Trimorphic heterogone fls. occur in many species; our native *O. violacea,* sometimes grown as a hardy perennial, presents long- and short-styled fls.; and our common native yellow-fld. species offer puzzling transitions between heterogone and homogone types. The small seeds are interestingly discharged from the fr. by the pressure of a fleshy outer envelope. The classical works on the genus are Jacquin's Oxalis Monographia (1794) and Zuccarini's Monographie der Amerikanischen Oxalis-Arten, and its Nachtrag (1825–31). Many of the earlier species, characterized by the relative length of stamens and styles, prove to be long-, short-, and mid-styled forms of identical species. The principal groups are sometimes segregated as distinct genera.

Generally speaking, the genus Oxalis is not highly esteemed by the florists. However, several species and varieties are used in masses for floral displays in botanical collections. The noteworthy species occasionally seen are *O. Bowiei, O. lasiandra* and its varieties *alba, cærulescens* and *lilacina, O. variabilis* and its varieties *alba* and *rubra, O. Simsii,* and *O. rosea.* When used for display during February or March, the bulbs or tubers should be cleaned and divided into convenient sizes during August or September. Excellent results may be accomplished by potting three bulbs, forming a triangle in each 4-inch spot, placing them just below the surface of the soil. The soil ingredients should consist of loam, leaf-soil and sand, in proportion to give a good porous medium. As root-action and growth increase, repot into 5- or 6-inch pots, which will carry them throughout the flowering period. Occasionally the crowns have a tendency to rise above the level of the soil; these may be lowered during repotting. When the plants are well rooted, periodical watering with organic fertilizer will help the development of good substantial flowers. During growth place the plants on the side stages near the glass in a temperature of 60° F. After the flowering period gradually reduce the water-supply and finally place in a cool cellar for the resting-period, or under the greenhouse bench, laying the pots side down. Specimen clumps are an acquisition planted below the benches in the floral display house; under these conditions they will practically naturalize themselves. Plants are also conveniently grown as common house plants, either in hanging-baskets or as pot-plants for the window during the summer months. When dormant they are easily stored in the cellar. A disappointing feature is the partial closing of the flowers during dull weather. (G. H. Pring.)

A. *Producing neither tubers nor bulbs.*

B. *Leafy-stemmed.*

C. *Lfts. notched at end.*

D. *Fls. red or rosy.*

1. **ròsea,** Feuill. Tall, erect: petioles scarcely 1 in. long: fls. long-stalked, in open irregularly forked cymes on long axillary peduncles, rather large, rosy with deeper veins. Chile. B.M. 2830. B.R. 1123 (as *O. floribunda*).

2. **Símsii,** Sweet. Resembling the preceding but more delicate: fls. deep red. Chile. B.M. 2415.

DD. *Fls. yellow.*

E. *Sts. erect.*

3. **Ortgièsii,** Regel. Fig. 2687. Red-tinged: st. tall, rather succulent: petioles long; lfts. deeply notched, with acute tips: fls. in close forked cymes on long axillary peduncles, small, yellow with deeper veins. Peru. Gt. 1875:817.

2688. Oxalis corniculata.

4. **valdiviénsis,** Barn. (*O. valdiviàna,* Hort.). St. short: lvs. clustered; petioles long: fls. in close umbels on long axillary peduncles, small, yellow with reddish veins. Chile.

EE. *Sts. low or creeping.*

5. **corniculàta,** Linn. (*O. stricta.* Linn.). Fig. 2688. Slender, prostrate, often rooting, loosely hairy: lfts. obcordate. Var. **atropurpùrea,** Planch. (*O. tropæoloìdes,* Schlecht.). Spreading, red-purple: fls. few, in umbels on rather short axillary peduncles, small, yellow. Eu. F.S. 12:1205; 19:1968 (a form with variegated lvs.). R.H. 1897, p. 499.—A closely related smaller plant common everywhere as a greenhouse weed, especially in agave and cactus tubs, is the tropical *O. rèpens,* Thunb.

CC. *Lfts. entire, separated.*

6. **delicàta,** Pohl. St. slender, erect, branching: lfts. ovate or lance-ovate: fls. in forked cymes on long axillary peduncles, small, pale rosy. Brazil.

7. **díspar,** N. E. Br. St. rather stout, tall, erect, branching: lfts. lanceolate, subacuminate, heavy-veined: fls. nearly sessile, in compact cymes on long axillary peduncles, rather small, golden. Guiana. B.M. 7794.

BB. *Lvs. and scapes from scaly ends of the rootstocks.*

8. **oregàna,** Nutt. Low: lfts. broadly obcordate, 1–2 in. wide: fls. white or rosy, yellowish at base, deeper veined. N. W. coast.

9. **Acetosélla,** Linn. Scarcely half as large in its various dimensions, otherwise very similar. E. U. S. and Eu. Fl. Dan. 980.—Often taken for the shamrock. Like the preceding, used sparingly in rockeries.

AA. *Producing tubers: not leafy-stemmed.*

10. **rùbra,** St. Hil. Lvs. spreading, long-petioled, thin, somewhat hairy, obcordate: fls. in usually compound umbels, rosy with deeper veins. Brazil. Gn. 50, p. 511 (as *O. floribunda*).—Forms occur also with lilac or white fls.

11. **enneáphylla,** Cav. Fig. 2689. Lvs. crowded; lfts. 9–20, glaucous, ½in. long, obcordate-cuneate, nearly sessile: fls. large, solitary, white, with lavender veins. Falkland Isls. Gn. 52:202; 73, p. 339. G.C. III. 49:414. G.M. 50:565. G. 34:717; 36:719.—A rosy-fld. form is var. *ròsea,* Hort.

12. **adenóphylla,** Gillies. (*O. Bustillòsii,* Phil.). Lvs. crowded; lfts. 12–22, glaucous, ½in. long, obcordate-cuneate with short gland-like base: fls. large, solitary or in few-fld. umbels, rosy-tinged with deeper veins and base. Chile. B.M. 8054. G.C. III. 46:164; 55. 400. Gn. 75, p. 358. G. 35:237.

AAA. *Producing bulbs.*

B. *Bulbs loosely scaly: not leafy-stemmed.*

C. *The bulbs compound, of numerous small ones: lfts. 3.*

13. **Martiàna,** Zucc. (*O. úrbica,* St. Hil. *O. bipunctàta,* Graham. *O. floribúnda,* Lehm. *Ionóxalis Martiàna,* Small). Somewhat long-hairy: lvs. long-petioled, thin, obcordate, orange-warty beneath, at least around the margin: fls. in loose usually compound umbels, rosy. Trop. Amer. B.M. 2781, 3938.

CC. *The bulbs simple.*

14. **tetraphýlla,** Cav. (*Ionóxalis tetraphýlla,* Rose). Lfts. mostly 4, 1 in. long, inversely deltoid, retuse, each crossed by a purple band: fls. rather few in simple umbels, lilac or rosy. Mex. Cav. Icon. 237. G.M. 39, p. 403 (as *O. Deppei*). L.B.C. 8: 790.

15. **Déppei,** Lodd. (*Ionóxalis Déppei,* Small). Differs chiefly in the lfts. being truncate instead of notched at apex. Mex. L.B.C. 15:1500.

16. **lasiándra,** Zucc. (*Ionóxalis lasiándra,* Rose). Lfts. 5–10, several inches long, oblong, spatulate, entire at end, glabrous: fls. in crowded umbels, rosy crimson. Mex. B.M. 3896.—Under the variously used name "*floribunda*" said to occur in the color varieties *álba, cæruléscens* and *lilácina.*

BB. *Bulbs firm, usually fusiform: lfts. 3.*

C. *Fls. umbelled, large: acaulescent.*

17. **Bòwiei,** Herb. (*O. Bowieàna,* Hort. *O. purpùrea,* Hort.). Fig. 2690. Lvs. spreading and large, fleshy, deep green; lfts. obovate, more or less notched: fls. bright rose-red. Cape. B.R. 1585. B. 1:25. R.H. 1858, p. 120. Gn. 10, p. 159; 37:508.

18. **cérnua,** Thunb. (*Bolbóxalis cérnua,* Small). BERMUDA BUTTERCUP. Fig. 2691. Lvs. ascending, not very large or fleshy, often purplish or mottled; lfts. obcordate: fls. bright yellow. Cape. L.B.C. 12:1154. B.M. 237.—A form with double fls. is var. *plèna,* F.S. 19:1964.

CC. *Fls. solitary on bractless or 2-bracted peduncles.*

D. *Lfts. broad, notched: nearly acaulescent.*

19. **variábilis,** Jacq. (*O. grandiflòra,* Jacq. *O. láxula,* Jacq. *O. purpùrea láxula,* Hort. *O. rigídula,* Jacq. *O. suggilàta,* Jacq. *O. variábilis albiflòra,* Lindl.). Hairy: lvs. petioled, rather fleshy, often purplish: fls. large, white or shaded with rose, yellow at base. Cape. B.M. 1683. B.R. 1505.—A form with deep rosy fls. is var. *rùbra,* Jacq. (*O. purpùrea,* Jacq. *O. speciòsa,* Jacq. *O. venústa,* Lowe). B.M. 1712. A white form, var. *álba,* Hort., is grown.

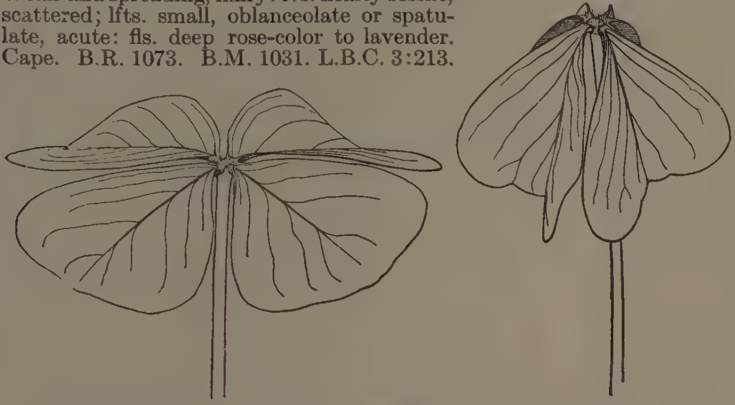
2689. Oxalis enneaphylla. (×½)

DD. *Lfts. narrow or small: leafy-stemmed.*

20. **versícolor,** Linn. (*O. elongàta,* Jacq.). Glandular: lvs. petioled, clustered at top of the st.: lfts. linear-

wedge-shaped, notched: fls. white, margined with red, yellow below. Cape. B.M. 155. F.S. 8:834.

21. **hírta,** Linn. (*O. fúlgida,* Lindl. *O. hirtélla,* Jacq. *O. multiflòra,* Jacq. *O. rosàcea,* Jacq. *O. rubélla,* Jacq.). Weak and spreading, hairy: lvs. nearly sessile, scattered; lfts. small, oblanceolate or spatulate, acute: fls. deep rose-color to lavender. Cape. B.R. 1073. B.M. 1031. L.B.C. 3:213.



2690. Leaves of Oxalis Bowiei, showing day and night positions.

O. japónica, Franch. & Sav. Lfts. broadly triangular, scarcely notched, and truncate. Otherwise similar to O. Acetosella. Japan.—*O. violàcea,* Linn. Lvs. rather fleshy, glabrous: fls. in simple umbels, rose-violet. E. U. S. B.M. 2215. Mn. 5:121.—Scarcely useful, except for hardy borders or rockeries.

William Trelease.

OXÈRA (meaning dubious, probably referring to sourness). *Verbenàceæ.* Shrubby often climbing plants, useful for growing under glass for the showy flowers, but little known horticulturally.

Leaves opposite, entire, leathery: fls. whitish or yellowish, in twice- or thrice-forked cymes, varying greatly in form of calyx and corolla, but the latter always 4-lobed, and wide-throated: drupes 4-parted or by abortion reduced to a single segm.—Species about two dozen, New Caledonia.

pulchélla, Labill. Lvs. 2–5 in. long, stalked, the lower ones oblong-lanceolate: calyx conspicuous, loose, composed of 4 more or less united greenish yellow sepals, each ½–¾in. long. B.M. 6938. Gn. 33:510; 45, p. 333. I.H. 36:76. J.H. III. 30:33; 42:39; 55:521. G.C. III. 3:209. R.H. 1890, p. 274.—Once offered by John Saul, Washington, D. C. Also cult. outdoors in S. Calif. It needs but a glance at any of the colored portraits of *O. pulchella* to see that it is one of the most interesting climbers cult. in hothouses. It has ivory-white trumpet-shaped sweet-scented fls. 2 in. long and 1 in. across, borne profusely in clusters of a dozen or more. A plant 2 years old from cuttings will clothe the rafters and bloom freely, the weight of the clusters causing the fls. to droop gracefully. The prominent calyx suggests *Clerodendron Thompsonæ,* a near relative. As the corolla-tube leaves the calyx, it makes a bend and then broadens into a funnel-shaped fl., with the 4 lobes scarcely spreading. The appearance of the fls. is enhanced by the long style and the 2 stamens, which are thrust out and strongly curved. It is reported as thriving in a winter temperature of 55–60°; it requires a warmer place than the ordinary greenhouse. It blooms well in the winter months. It prop. readily by cuttings placed around the side of a pot; also from seeds, which it matures in considerable numbers.

Wilhelm Miller.
L. H. B.†

OX-EYE: in America, *Heliopsis;* in Europe, *Buphthalmum.* Ox-eye daisy: *Chrysanthemum Leucanthemum* and *Rudbeckia hirta.*

OXLIP: *Primula elatior.*

OXYÁNTHUS (Greek, *sharp flower;* referring to the acute lobes of the corolla and calyx). *Rubiàceæ.* African trees and shrubs, allied to the cape jasmine (Gardenia). They are remarkable for their extremely long and slender corolla-tubes, which are topped by a five-pointed star of spreading narrow lobes.

Leaves opposite: fls. usually white, in axillary racemes or panicles; calyx-tube truncate, or with 5 short teeth; corolla salver-shaped, throat glabrous; stamens 5, inserted at the mouth of the tube; ovary 2-celled, except in 1 species; style usually exserted; stigma usually spindle-shaped or club-shaped, 2-cut at the top; ovules numerous, not immersed in the 2 fleshy placentæ: fr. a sort of berry.—Species 30–40, mostly in Trop. Afr., some in S. Afr.

natalénsis, Sond. Branches, lvs. and calyx glabrous: lvs. elliptic-oblong or ovate-lanceolate, shortly acuminate, entire, 7–8 in. long, 3 in. wide: racemes axillary, loosely 16–20-fld.; fls. white, fragrant; corolla-tube about half the length of the lvs. Wet places in woods, Natal.—Cult. outdoors in S. Fla., and in Eu. under glass.

ísthmia, Hort. Described as a splendid flowering shrub in S. Fla., similar to the above but with larger calyces and possibly more fragrance. Probably S. American, and requiring further study. The name is not identified botanically.

O. tubiflòrus, DC. (Gardenia tubiflora, Andr.). Hispidulous-puberulous: lvs. obtusely rounded or somewhat eared at the base: fls. 6–7 in. long, at first creamy white, then tawny or ochrous: fr. terete, not grooved. Trop. Afr. F.S. 7:737. B.M. 1992 (as *O. speciosus*) 4636. J.F. 3:245.

Wilhelm Miller.
L. H. B.†

OXYDÉNDRUM (Greek, *sour tree;* from the acid taste of the foliage). Also written *Oxydéndron. Ericàceæ.* Sour-Wood or Sorrel-Tree. Ornamental tree grown for its white flowers appearing in summer and the handsome foliage turning scarlet in autumn.

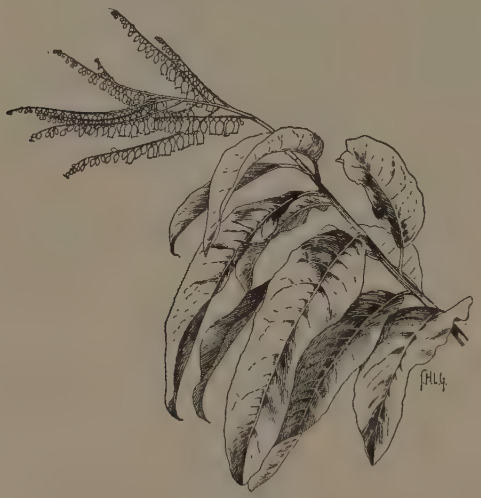
2691. Oxalis cernua.

Deciduous: lvs. alternate, petioled, serrulate: fls. whitish in terminal panicles composed of 6 or more

1-sided racemes; calyx divided nearly to the base into 5 sepals valvate in bud; corolla cylindric-ovoid, puberulous, with 5 minute lobes; stamens 10; anthers linear-oblong, opening from the apex to the middle; style slightly exserted: caps. ovoid-pyramidal, 5-valved, loculicidally dehiscent, many-seeded; seeds slender, the reticulate loose seed-coat produced at the ends into slender points.—One species in E. N. Amer.

A handsome medium-sized tree with slender spreading branches, rather large, generally oblong bright green leaves turning scarlet in fall and with small white flowers, followed by small grayish capsules nearly as conspicuous as the flowers. It is hardy North and of easy culture in any moderately good soil, but rather slow in becoming established and of rather slow growth. It is useful in shrubberies, along the borders of woods, or even within the woodland, since it endures shade fairly well. Propagation is by seeds treated like those of Andromeda.

arbòreum, DC. (*Andrómeda arbòrea,* Linn.). Fig. 2692. Tree with deeply fissured bark, occasionally to 60 ft. high: branchlets glabrous: lvs. slender-stalked, oblong-lanceolate, acuminate, broadly narrowed at the base, serrulate, glabrous except a few hairs on the midrib, 4–7 in. long: panicle 6–10 in. long; fls. ⅓in. long: caps. ⅓–½in. long. June–Aug.; fr. in Sept., Oct. Pa. to Ind. and along the mountains to Fla. and La. S.S. 5:235. B.M. 905. L.B.C. 13:1210. G. 27:415. F.E. 24:131. M.D.G. 1904:253. ALFRED REHDER.†



2692. Oxydendroum arboreum. Sour-wood or sorrel-tree. (×⅓)

OXYLÒBIUM (Greek, *sharp pod*). Including *Callístachys. Leguminòsæ.* One of many genera of Australian shrubs with pea-like flowers which are little known in cultivation.

Undershrubs or shrubs: lvs. very short-stalked, opposite or more or less whorled, rarely scattered or alternate: fls. in terminal or axillary racemes; petals clawed; stamens free; ovary villous, sessile or stalked, 4–30-ovuled. Nearest to Chorizema, but the keel is about as long as the wings, while in Chorizema the keel is much shorter. The following species was considered the type of another genus; it is distinguished from all other species of Oxylobium by the incomplete dehiscence of the pod.—Species nearly 30, of which perhaps a dozen have been cult. in Europe. Their fls. are yellow, or more or less flushed with red on the keel or the base of the standard. *O. Callistachys* is perhaps the best for conservatories. In America it is cult. only in S. Calif.

Callístachys, Benth. Tall shrub: lvs. mostly in irregular whorls of 3, varying from ovate-oblong and 1½–2 in. long to lanceolate and 4–5 in. long, leathery, silky-pubescent beneath when young: racemes oblong or pyramidal, 2–6 in. long. B.R. 216 (as *Callistachys lanceolata*). B.M. 1925 (as *C. ovata*). P.M. 8:31 (as *C. longifolia*). L.B.C. 20:1983 (as *C. retusa*). J.H. III. 35:35. WILHELM MILLER.

OXYPÉTALUM (Greek, *sharp petal*). Incl. *Tweèdiea. Asclepiadàceæ.* S. American and largely Brazilian herbs or subshrubs, twining or not: lvs. opposite: calyx 5-parted; corolla deeply 5-cut, short-tubed; scales of the corona 5, fastened at the base of the corolla and staminal tube.—Species about 100, not widely known in cult.

cærùleum, Decne. Herbaceous, but more or less woody below, downy: lvs. short-petioled, oblong, but cordate-hastate at the base: peduncles axillary from one of each pair of the upper lvs., 3–4-fld.: corolla-lobes spreading: scales of the corona 5, erect, darker blue, fleshy, exserted, recurved and notched at the apex. B.M. 3630 (as *Tweediea versicolor*).—*O. cæruleum* is a tender twining plant from Argentina with changeable 5-lobed fls. about an inch across. The fls. are said to be pale blue when they first open, then purplish, and when withered lilac. Not cult. in Amer., but apparently desirable for cult. here.

solanoìdes, Hook. & Arn. (*Tweèdiea floribúnda,* Hort.). Erect, little branched, shrubby or somewhat so, 6 ft.: lvs. lanceolate to oblong-cordate, acute, tomentose, the sinus at the base deep: fls. not so large as in *O. cæruleum,* bluish tinged rose (or dull purplish red), in terminal or axillary few-fld. cymes; staminal crown of 5 fleshy parts. Brazil. B.M. 4367. L. H. B.†

OXÝPOLIS (derivation not explained). *Umbellíferæ.* A few erect glabrous wet-ground perennials in N. Amer., seldom used in bog- and swamp-gardening; formerly known as Tiedemannia. The plants have tuberous clustered roots: lvs. pinnate or ternate, sometimes reduced to hollow and jointed phyllodia: fls. small, white, in compound mostly involucrate and involucellate umbels: fr. glabrous, ovate or obovate, dorsally flattened, ribbed or winged. *O. rígidius,* Raf. (*Tiedemánnia rígida,* Coult. & Rose), COWBANE, is a poisonous herb, 2–6 ft. tall, growing in swamps, N. Y. to Minn. and Fla., which was once offered in the trade: lvs. pinnate; lfts. oblong to ovate-lanceolate or nearly linear, entire or sparsely dentate. Probably not now listed.

OXYTENANTHÈRA: *Bamboo.*

OXÝTROPIS (Greek, *sharp keel*). *Leguminòsæ.* Perennial herbs, half-shrubs and shrubs.

The genus is like Astragalus, but is distinguished by a subulate beak at the tip of the keel. The American species are tufted with numerous short sts. from a hard and thick rootstock: lvs. odd-pinnate with 7–16 pairs of lfts., which are woolly and white beneath: calyx tubular or tubular-campanulate: fls. pea-shaped (papilionaceous), with an erect standard, wings elongated, keel occasionally with thorn-like apex, longer or shorter than the wings, in racemes, spikes or heads and range from yellow, white through blue and purple to crimson: pods many-seeded.—About 234 species with the center of their distribution in Asia from Siberia to the Caucasus Mts. and Turkestan. A few species reach the mountains of Cent. Eu. None occurs in Afr. About 18 species found in the Rocky Mts. are referred to Aragallus, a generic name brought into prominence by E. L. Greene (Pittonia 3:208) and reviewed in Erythea 7:57–64 (1899) without definition. *O. Lambertii* is poisonous to stock. It is one of the most characteristic loco-weeds of the W. (see *Poisonous Plants*). Locoed sheep are difficult to herd, as they stray away from the flock; slight locomotor ataxia is manifested with twitching of the eyelids and grinding motion of the jaws. About a dozen kinds of Oxytropis are cult. in Eu., mostly as rock plants. They are hardy, easily prop. by seeds or division, and prefer a dry, sandy loam. These plants are of minor value horticulturally.

A. *Stipules free: pod 1-celled.*

defléxa, DC. (*Arágallus defléxus,* Heller). Leafy-stemmed to nearly stemless, a foot or less tall with crowded lfts. in 12–16 pairs, lanceolate to oblong, 3–6 lines long: fls. rather small, about 3 lines long, pale purple: pods pendant, 1-celled, many times exceeding the calyx. Mountains, Brit. Amer. to Colo. and Utah. Fls. June, July.—Prefers moist open ground throughout the eastern Rockies at lower altitudes. A very distinct species by reason of its stipules almost free, or only slightly adnate to the base of the petioles.

AA. *Stipules decidedly adnate to petioles: pods not pendant, 2-celled.*

B. *Lvs. strictly pinnate; lfts. opposite.*

Lámbertii, Pursh. (*Arágallus Lámbertii,* Greene). Fig. 2693. A tufted perennial with strong taproot and several erect scapes, 4–20 in. tall: spike short-oblong, densely fld.; fls. usually purple or violet: lfts. about 7 pairs: pod broadly or narrowly oblong, silky pubescent, firm-coriaceous, 2-celled. Fls. June, July. Includes *O. campéstris,* Hook. Fl. Bor. Am. in part, also *Arágallus pátens, A. angustàtus* and *A. atropurpùreus* of Rydberg. B.M. 2147 (dark blue). B.R. 1054 (blue). V. 3:138.—Aven Nelson, in Erythea 7:62, says that the specific name should be kept for the purple-violet-fld. forms. D. M. Andrews offers a crimson-fld. form and also var. **spicàta,** which has large spikes of white fls. Common along the Great Plains from Sask. to New Mex. and in the foothills where it is held to be responsible, as a loco-weed, for the poisoning and death of sheep and cattle. A clue as to its cultural requirements may be had from its wild habitat in open ground growing in masses of considerable extent.

BB. *Lfts. verticillate, numerous.*

spléndens, Douglas. A very showy, densely silky, silvery-villous, stemless, tufted plant, 4–18 in. tall: lfts. numerous, fascicled in 3's or 4's, as if verticillate: scape spicately, many-fld.; fls. bright-blue to deep purple, about ½in. long in June: pod ovate, hairy, much longer than the calyx. Native to open ground on the eastern slopes of the Rockies and in dry alpine meadows.

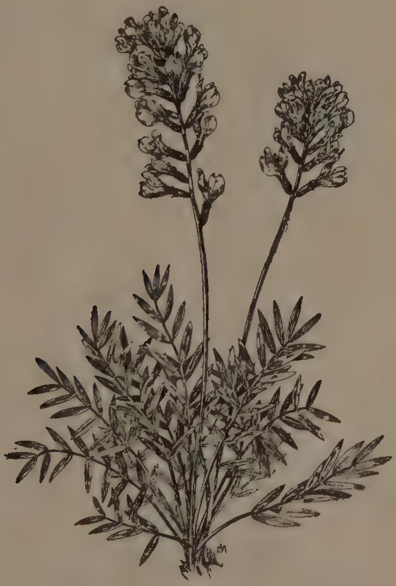
O. hýbrida, Bruegg. Probably a hybrid between O. campestris and O. sericea or O. Hallesi. Perennial, from Switzerland.—*O. ochroleùca,* Bunge. Lvs. pinnate, 3–4 in. long, with oblong-lanceolate lfts.: fls. small, drooping, in short racemes, yellowish white. N. Asia.—*O. villòsa,* Blank (Aragallus villosus, Rydb.). Densely cespitose: foliage silvery white: fls. creamy white, in dense spikes; calyx silky, villous: pod white-silky tipped with hooked beak. Mont.—*O. yunnanénsis,* Franch. Sts. many, woody: lfts. in 8–11 pairs, lanceolate: fls. in dense head of 7–12, deep blue. Yunnan.

JOHN W. HARSHBERGER.

OXYÙRA: *Layia.*

OYSTER PLANT or SALSIFY: *Tragopogon porrifolius.*

OZOTHÁMNUS: *Helichrysum diosmæfolium* (*O. rosmarinifolius*).



2693. Oxytropis Lambertii. (×⅓)
